

# THE ANALYSIS OF THE CHARACTERS OF THE LIE REPRESENTATIONS OF THE GENERAL LINEAR GROUP

H. O. FOULKES

1. If a free Lie ring has  $n$  generators and  $A$  is a nonsingular  $n \times n$  matrix of complex elements, then when the generators undergo a linear transformation of matrix  $A$ , the module of all forms of degree  $m$  in the generators is mapped into itself by a linear transformation of matrix  $L_m(A)$  on a set of basis elements. The mapping  $A \rightarrow L_m(A)$  is a representation of the full linear group known as the  $m$ th Lie representation [1]. The character of this representation has been shown [2] to be  $\gamma_m = m^{-1} \sum_{d|m} \mu(d) s_d^{m/d}$ , where  $\mu(k)$  is the Möbius function of the integer  $k$ , and  $s_r$  is the sum of the  $r$ th powers of the eigenvalues of  $A$ . The decomposition of the  $m$ th Lie representation into its irreducible constituents is in exact correspondence with the analysis of the symmetric function  $\gamma_m$  into Schur functions. When  $m$  is prime there is a simple rule for the coefficient  $\alpha_\lambda$  of any  $S$ -function  $\{\lambda\}$  in  $\gamma_m$ , [2], but there is no such rule when  $m$  is composite. Since  $s_d^{m/d} = \sum_\lambda \chi_\lambda^{m/d} \{\lambda\}$ , where  $\chi_\rho^\lambda$  is the irreducible character of the class  $(\rho)$  of the symmetric group  $\mathfrak{S}_m$  corresponding to the partition  $(\lambda)$  of  $m$ , it follows that [10],

$$\alpha_\lambda = \frac{1}{m} \sum_{d|m} \mu(d) \chi_\lambda^{m/d}.$$

The calculation of  $\alpha_\lambda$  thus reduces to the calculation of characters of the form  $\chi_\lambda^{m/d}$ .

It is the purpose of this note to suggest, in §2, a method of calculation of these characters, and, in §3, to indicate some relations satisfied by the  $\alpha_\lambda$ .

2. The well known formulae for  $\chi_{1^m}^\lambda$  are

$$\chi_{1^m}^\lambda = \frac{m! \prod_{r < s} (\lambda_r - \lambda_s - r + s)}{\prod_r (\lambda_r + p - r)!}$$

where  $p$  = number of parts in  $(\lambda)$ ;

$$\chi_{1^m}^\lambda = \frac{m!}{\prod_{r,s} (\lambda_r + \bar{\lambda}_s - r - s + 1)},$$

---

Received by the editors July 18, 1958 and, in revised form, October 8, 1958.

where  $(\bar{\lambda}) = (\bar{\lambda}_1, \bar{\lambda}_2, \dots)$  is the partition conjugate to  $(\lambda)$ ;

$$\chi_{1^m}^\lambda = \frac{m!}{H_\lambda},$$

where  $H_\lambda$  is the product of the hook-lengths  $h_{ij}$  in the hook-graph of  $(\lambda)$  [3]. These give the coefficient of  $\{\lambda\}$  in  $s_1^m$ . An alternative method, which extends to  $\chi_r^{\lambda m/r}$ , the coefficient of  $\{\lambda\}$  in  $s_r^{m/r}$ , is by evaluation of certain determinants; [4, pp. 134–135; 5]. Thus to find  $\chi_{10}^{531^2}$  we evaluate

$$10! \begin{vmatrix} 1 & 1 & 1 & 1 \\ 5! & 6! & 7! & 8! \\ 1 & 1 & 1 & 1 \\ 2! & 3! & 4! & 5! \\ \cdot & 1 & 1 & 1 \\ & & 1! & 2! \\ \cdot & \cdot & 1 & 1 \\ & & & 1! \end{vmatrix}, \text{ or preferably } 10! \begin{vmatrix} 35 & 4 \\ 8! & 5! \\ 1 & 1 \\ 5! & 2! \end{vmatrix},$$

obtained respectively from

$$\{531^2\} = \begin{vmatrix} \{5\} & \{6\} & \{7\} & \{8\} \\ \{2\} & \{3\} & \{4\} & \{5\} \\ \cdot & \{0\} & \{1\} & \{2\} \\ \cdot & \cdot & \{0\} & \{1\} \end{vmatrix} \text{ and } \{531^2\} = \begin{vmatrix} \{51^3\} & \{21^3\} \\ \{5\} & \{2\} \end{vmatrix},$$

[6] giving 567. To find the coefficient of  $\{531^2\}$  in  $s_r^{10/r}$  we replace every  $\{k\}$  in the first of these determinants by zero if  $k$  is not a multiple of  $r$ , and by  $1/(k/r)!$  if it is. Multiplying the determinant by  $(10/r)!$  gives the required coefficient. Thus the coefficients of  $\{531^2\}$  in  $s_2^5, s_5^2, s_{10}$  are respectively

$$5! \begin{vmatrix} \cdot & \frac{1}{3!} & \cdot & \frac{1}{4!} \\ 1 & \cdot & \frac{1}{2!} & \cdot \\ \cdot & 1 & \cdot & 1 \\ \cdot & \cdot & 1 & \cdot \end{vmatrix} = 15, \quad 2! \begin{vmatrix} 1 & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & 1 \\ \cdot & 1 & \cdot & \cdot \\ \cdot & \cdot & 1 & \cdot \end{vmatrix} = 2, \text{ and zero,}$$

giving the coefficient of  $\{531^2\}$  in  $\gamma_{10}$  as 55. This was given as 53 by Thrall [1], but was later corrected by Brandt [2].

Justification of the above procedure is given conveniently by the use of the differential operator  $D_\lambda$  obtained from  $\{\lambda\}$  by replacing  $s_i^a$  by  $i^a \partial^a / \partial s_i^a$ , [7]. Thus the coefficient of  $\{\lambda\}$  in  $s_1^m$  is  $D_\lambda s_1^m$ , and if  $(\lambda) = (\lambda_1, \lambda_2, \dots, \lambda_p)$ , the coefficient can be written as

$$\begin{vmatrix} D_{\lambda_1} & D_{\lambda_1+1} & \cdots & D_{\lambda_1+p-1} \\ D_{\lambda_2-1} & D_{\lambda_2} & \cdots & D_{\lambda_2+p-2} \\ D_{\lambda_3-2} & D_{\lambda_3-1} & \cdots & D_{\lambda_3+p-3} \\ \cdots & \cdots & \cdots & \cdots \\ D_{\lambda_{p-p+1}} & \cdots & \cdots & D_{\lambda_p} \end{vmatrix} s_1^m$$

and the only effective part of each  $D_k$  is  $(k!)^{-1} \partial^k / \partial s_1^k$ . Then in  $D_\lambda s_1^{m/r}$  the only effective part of each  $D_k$  is

$$\frac{1}{k!} \frac{k!}{r^{k/r} (k/r)!} r^{k/r} \frac{\partial^{k/r}}{\partial s_1^{k/r}} = \frac{1}{(k/r)!} \frac{\partial^{k/r}}{\partial s_1^{k/r}}$$

so that we get zero elements in the determinant when  $k$  is not a multiple of  $r$ , and elements  $1/(k/r)!$  when  $k$  is a multiple of  $r$ .

3. We now list a number of results concerning the  $\alpha_\lambda$ .

I. When  $m$  is prime,  $\alpha_\lambda$  is the integer nearest to  $m^{-1} \chi_1^\lambda$  [2].

II.  $\alpha_m = 0$  for  $m > 1$ , [10], and  $\alpha_1^m = 0$  for  $m > 2$ .

These follow since  $\alpha_m = m^{-1} \sum \mu(d)$ , and  $\alpha_1^m = m^{-1} \sum (-1)^{m+m/d} \mu(d)$ .

III.  $\alpha_{m-1,1} = 1$  for  $m > 1$ , [10], and  $\alpha_{21^{m-2}} = 1$  for  $m > 2$ .

These follow since

$$\chi_1^{m-1,1} = m - 1, \quad \text{and} \quad \chi_a^{m-1,1} = -1 \quad \text{for } a > 1, b \geq 1,$$

[8, p. 137] and so

$$\alpha_{m-1,1} = m^{-1} \left[ m - 1 - \sum_{d \neq 1} \mu(d) \right] = 1 \quad \text{for } m > 1,$$

$$\alpha_{21^{m-2}} = m^{-1} \left[ m - 1 - \sum_{d \neq 1} (-1)^{m+m/d} \mu(d) \right] = 1, \quad \text{for } m > 2.$$

IV. If  $m$  is odd or a multiple of four, then  $\alpha_\lambda = \alpha_{\tilde{\lambda}}$ . It is well known that  $\chi_a^{\lambda/d} = \chi_a^{\tilde{\lambda}/d}$  for odd values of  $d$ , and also for even  $d$  whenever  $m/d$  is even. This proves IV.

When  $m$  is twice an odd integer,  $\chi_a^{\lambda/d} = -\chi_a^{\tilde{\lambda}/d}$  for even  $d$ , and in this case  $\gamma_m$ , expressed in power sums, can be written as  $P + Q$ , where the coefficients of  $\{\lambda\}$  and  $\{\tilde{\lambda}\}$  are the same in  $P$ , but have opposite signs in  $Q$ .  $P$  has all  $s_d^{m/d}$  with odd  $d$ , and  $Q$  has all  $s_d^{m/d}$  with even  $d$ . There are certain partitions  $(\lambda)$  for which the coefficient of  $\{\lambda\}$  in  $Q$  is zero, and for these  $\alpha_\lambda = \alpha_{\tilde{\lambda}}$ .

The following three results are typical of many which can be obtained by equating appropriate coefficients when the right hand side of

$$m^{-1} \sum_{d|m} \mu(d) s_d^{m/d} = \sum_{\lambda} \alpha_{\lambda} \{ \lambda \}$$

is expressed in terms of power sums by writing

$$\{ \lambda \} = (m!)^{-1} \sum_{\rho} h_{\rho} \chi_{\rho}^{\lambda} S_{\rho},$$

where  $h_{\rho}$  is the order of the class  $(\rho) = 1^{x_1} 2^{x_2} \dots$  of  $\mathfrak{S}_m$ , and  $S_{\rho} = s_1^{x_1} s_2^{x_2} \dots$ .

V.  $\sum_{\lambda} \chi_{\lambda}^{\lambda} \alpha_{\lambda} = (m-1)!$  This is obtained by equating coefficients of  $s_1^m$ .

VI.  $\sum_{\lambda=(m-r, 1^r)} (-1)^r \alpha_{\lambda} = \mu(m)$ . Obtained by equating coefficients of  $s_m$ .

VII. If  $S$ -functions of ranks one and two are written respectively in Frobenius notation as

$$\{ \lambda \} = \left\{ \begin{matrix} X_r \\ Y_r \end{matrix} \right\} \quad \text{and} \quad \{ \nu \} = \left\{ \begin{matrix} X_{t_1} & X_{t_2} \\ Y_{t_1} & Y_{t_2} \end{matrix} \right\},$$

and  $a, b$  are any two unequal positive integers such that  $a+b=m$ , then  $\sum_{\lambda} \theta_r \alpha_{\lambda} + \sum_{\nu} \phi_t \alpha_{\nu} = 0$ , where

$$\begin{aligned} \theta_r &= (-1)^{Y_r} && \text{if } m > X_r \geq a, \\ &= 0 && \text{if } a > X_r \geq b, \\ &= (-1)^{Y_r+1} && \text{if } b > X_r \geq 0, \\ \phi_t &= (-1)^{Y_{t_1}+Y_{t_2}} && \text{if } X_{t_1} + Y_{t_1} = a - 1, \\ &= (-1)^{Y_{t_1}+Y_{t_2}+1} && \text{if } X_{t_1} + Y_{t_2} = a - 1, \\ & && \text{or if } X_{t_2} + Y_{t_1} = a - 1, \\ &= 0 && \text{otherwise.} \end{aligned}$$

This result follows by equating coefficients of  $s_a s_b$ , [9]. Other special relations of this kind may be obtained by equating coefficients of  $s_a s_b s_c$ , and of other terms. They depend on a knowledge of expressions such as  $\theta_r, \phi_t$  above for the appropriate characteristics of  $\mathfrak{S}_m$ .

VIII. If  $h_d$  is the order of the class  $(d^{m/d})$  of  $\mathfrak{S}_m$ , then

$$\sum_{\lambda} \alpha_{\lambda}^2 = \frac{(m-1)!}{m} \sum_d \frac{1}{h_d},$$

for square free values of  $d$ .

We have  $D_{\gamma_m} \gamma_m = \sum_{\lambda} \alpha_{\lambda} D_{\lambda} \sum_{\lambda} \alpha_{\lambda} \{ \lambda \} = \sum_{\lambda} \alpha_{\lambda}^2$ . Also

$$\begin{aligned}
 D_{\gamma_m} \gamma_m &= m^{-1} \left[ \sum_d \mu(d) d^{m/d} \frac{\partial^{m/d}}{\partial s_d^{m/d}} \right] m^{-1} \sum_d \mu(d) s_d^{m/d} \\
 &= (m^2)^{-1} \left[ \sum (\mu(d))^2 d^{m/d} (m/d)! \right] \\
 &= (m^2)^{-1} \sum \frac{m!}{h_d}
 \end{aligned}$$

for square free values of  $d$ .

More explicit results may be written down when  $m$  has some prescribed form. Thus when  $m$  is a prime  $p$ ,  $\sum \alpha_\lambda^2 = p^{-1} [1 + (p-1)!]$ , and when  $m$  is the product of two distinct primes  $p, q$ ,

$$\sum \alpha_\lambda^2 = \frac{1}{pq} [(pq-1)! + p^{q-1}(q-1)! + q^{p-1}(p-1)! + 1].$$

When  $m$  is not twice an odd number we have  $\alpha_\lambda = \alpha_{\tilde{\lambda}}$  by IV. But if  $m = 2(2k+1)$ , then by evaluating  $D_{\gamma_m} \tilde{\gamma}_m$  in two ways, we obtain a further result;

IX. If  $m$  is twice an odd number, then  $\sum_\lambda \alpha_\lambda \alpha_{\tilde{\lambda}} = (m-1)!/m \cdot \sum_d (-1)^{d+1} (h_d)^{-1}$  for square free values of  $d$ .

Some results on the characters of the Lie representations in the special case when the number of generators is two have been given in a recent paper by Davis [10].

I am indebted to the referee for his comments.
