

## SOME CHARACTERIZATIONS OF SEMI-LOCALLY CONNECTED SPACES

YU-LEE LEE<sup>1</sup>

Let  $(X, \mathfrak{u})$  be a connected  $T_1$ -space and let  $\mathfrak{C}$  be the class of all closed connected subsets of  $(X, \mathfrak{u})$ . Define the operator  $K$  on all the subsets of  $X$  as follows:  $K(A)$  is the intersection of all the finite unions of elements of  $\mathfrak{C}$  which cover  $A$ . Then we see that  $K$  has the following properties:

- (1) If  $A \subset X$ , then  $K(A)$  is closed and  $\text{Cl}(A) \subset K(A)$ .
- (2) If  $A$  is connected in  $(X, \mathfrak{u})$ , then  $\text{Cl}(A) = K(A)$ .
- (3) If  $A$  is closed and connected, then  $K(A) = A$ .
- (4) The operator  $K$  satisfies the Kuratowski axioms.

Thus  $K$  defines a new topology  $\mathfrak{v}$  for  $X$ , we call  $\mathfrak{v}$  the derived topology of  $\mathfrak{u}$ .

- (5) The space  $(X, \mathfrak{v})$  is a connected  $T_1$ -space.
- (6) If  $A$  is connected in  $(X, \mathfrak{u})$ , then  $A$  is connected in  $(X, \mathfrak{v})$ .
- (7) If  $A$  is closed and connected in  $(X, \mathfrak{u})$ , then  $A$  is closed and connected in  $(X, \mathfrak{v})$ .
- (8) The topology  $\mathfrak{v}$  is contained in  $\mathfrak{u}$ .

Recall from [1] that a connected  $T_1$ -space  $X$  is said to be semi-locally connected (s.l.c.) at  $x$  provided there exists a local open base at  $x$  such that  $X - V$  has only a finite number of components for any  $V$  in the local open base at  $x$ . The space  $X$  is s.l.c. provided  $X$  is s.l.c. at every  $x$  in  $X$ .

**THEOREM 1.** *The connected  $T_1$ -space  $(X, \mathfrak{u})$  is s.l.c. if and only if  $\text{Cl}(A) = K(A)$  for any subsets  $A$  of  $X$ .*

**PROOF.** Suppose  $(X, \mathfrak{u})$  is s.l.c.,  $A \subset X$  and  $x \notin \text{Cl}(A)$ . Then there exists an open neighborhood  $V$  of  $x$  such that  $X - V$  is the union of a finite number of closed connected sets which cover  $A$ . Hence  $x \notin K(A)$  and therefore  $\text{Cl}(A) = K(A)$ .

Conversely suppose  $\text{Cl}(A) = K(A)$  for all  $A \subset X$  and  $U$  is an open neighborhood of a point  $x$  in  $X$ . Since  $\text{Cl}(X - U) = K(X - U)$ , we have  $x \notin K(X - U)$ . Therefore there exists a finite family of closed connected sets  $C_1, C_2, \dots, C_n$  which covers  $X - U$  and such that  $x \notin C_i$  for each  $i = 1, 2, \dots, n$ . Since  $X - \bigcup \{C_i: i = 1, 2, \dots, n\}$  is open and is contained in  $U$ , it follows that  $X$  is s.l.c. at  $x$ .

**THEOREM 2.** *Let  $(X, \mathfrak{U})$  be a connected  $T_1$ -space and let  $\mathfrak{V}$  be the derived topology of  $\mathfrak{U}$ . Then  $(X, \mathfrak{V})$  is s.l.c.*

**PROOF.** Since  $(X, \mathfrak{U})$  is a connected  $T_1$ -space by (5), we can consider the derived topology  $\mathfrak{W}$  of  $\mathfrak{U}$  with the defining operator  $J$ . Let  $\mathfrak{C}$  and  $\mathfrak{C}'$  be the families of all closed connected subsets of  $(X, \mathfrak{U})$  and  $(X, \mathfrak{V})$  respectively. By (1),  $\text{Cl}(A) \subset K(A) \subset J(A)$  for any  $A \subset X$ . Since by (7),  $\mathfrak{C} \subset \mathfrak{C}'$ , it follows that any finite cover of  $A$  by elements of  $\mathfrak{C}$  is a finite cover of  $A$  by elements of  $\mathfrak{C}'$ . Hence by definition of  $K$  and  $J$  we have  $K(A) \supset J(A)$ . By Theorem 1,  $(X, \mathfrak{V})$  is s.l.c.

**COROLLARY 1.** *A topological space  $(X, \mathfrak{V})$  is s.l.c. if and only if  $\mathfrak{V}$  is the derived topology of some connected  $T_1$ -space  $(X, \mathfrak{U})$ .*

**COROLLARY 2.** *A locally connected continuum  $(X, \mathfrak{U})$  is s.l.c.*

**PROOF.** Let  $A$  be a closed set in  $(X, \mathfrak{U})$  and  $p \notin A$ . Then there exists a finite family of closed connected sets which covers  $A$  but not  $p$ . Hence  $p \notin K(A)$  and  $K(A) = A$ . By Theorem 1,  $(X, \mathfrak{U})$  is s.l.c.

A mapping  $f$  of  $(X, \mathfrak{U})$  into  $(Y, \mathfrak{V})$  is called semi-connected if whenever  $A$  is a closed connected set in  $(Y, \mathfrak{V})$ ,  $f^{-1}(A)$  is a closed connected set in  $(X, \mathfrak{U})$ . The following theorem is a generalization of a result of Tanaka [2] and W. J. Pervin and N. Levine [3].

**THEOREM 3.** *A semi-connected mapping  $f$  from  $(X, \mathfrak{U})$  into a s.l.c. space  $(Y, \mathfrak{V})$  is continuous.*

**PROOF.** Let  $A$  be a closed subset of  $Y$ ; then

$$\begin{aligned} A &= \text{Cl}(A) = K(A) \\ &= \bigcap \{ \bigcup \{ C : C \in \mathfrak{C}' \} \} \end{aligned}$$

where  $\mathfrak{C}'$  is a finite family of closed connected subsets which covers  $A$ . Hence

$$f^{-1}(A) = \bigcap \{ \bigcup \{ f^{-1}(C) : C \in \mathfrak{C}' \} \}$$

is closed and  $f$  is continuous.

**THEOREM 4.** *If  $(X, \mathfrak{U})$  is a connected  $T_1$ -space, then the following statements are equivalent:*

- (a)  $(X, \mathfrak{U})$  is s.l.c.
- (b) Every semi-connected mapping  $f$  from a topological space  $Y$  into  $(X, \mathfrak{U})$  is continuous.
- (c) The identity mapping from  $(X, \mathfrak{V})$  onto  $(X, \mathfrak{U})$  is continuous where  $\mathfrak{V}$  is the derived topology of  $\mathfrak{U}$ .

**PROOF.** The previous theorem shows that (a) implies (b). The

identity mapping  $i$  is semi-connected, by (7). Hence (b) implies (c). If (c) holds then  $i$  is a homeomorphism. By Theorem 2,  $(X, \mathfrak{u})$  is s.l.c.

## A TECHNIQUE FOR CONSTRUCTING EXAMPLES

MARY ELLEN RUDIN

The word *space* in this paper will refer to Hausdorff spaces.

I have recently been asked the following questions.

1 (by the topology class of R. H. Bing). Is there a regular, sequentially compact space in which some nested sequence of continua intersect in a disconnected set?

2 (by E. Michael). Is there a normal, sequentially compact but not compact, space having a separable, metric, locally compact, dense subset?

Examples showing that the answer to both questions is yes, modulo the continuum hypothesis, are easily constructed using a technique I have often used before. The technique, described in §I, is perhaps more interesting than the particular examples which are given in §II. §III gives a variation of the technique and raises some questions.

I. This technique is useful in the construction of pathological spaces having nice dense subsets.

Let  $R$  be the wedge in the plane consisting of all points  $(x, y)$  such that  $0 \leq x \leq 1$  and  $0 \leq y \leq x$ ; let  $T = R - \{(0, 0)\}$ .

Let  $F$  be the set of all continuous real valued functions whose domain is the set of all positive numbers less than or equal to 1 and whose graph lies in  $T$ .

There is a natural partial ordering of the terms of  $F$ : if  $f$  and  $g$
