Quantum Probability Spaces

Stanley P. Gudder

1. Introduction. In [5] P. Suppes introduced the notion of a quantum probability space. He noted that such spaces may be used to describe the position and momentum of a quantum mechanical particle but cannot be used for more general systems. This author has considered quantum probability spaces not only because they are an interesting example of a nonclassical logic but because quantum mechanical phenomena are seen to develop in a quite transparent fashion in this case.

2. \( \sigma \)-classes and compatibility. Let \( \Omega \) be a nonempty set. A \( \sigma \)-class \( C \) of subsets of \( \Omega \) is a collection of subsets which satisfy
   
   (i) \( \Omega \subset C \);
   
   (ii) if \( a \in C \), then \( a' \in C \);
   
   (iii) if \( a_i \) are mutually disjoint, then \( \bigcup a_i \in C \), \( i = 1, 2, \ldots \);
   
   where we have denoted the complement of a set \( a \) by \( a' \). A state \( m \) on \( C \) is a map \( m : C \to [0, 1] \) such that
   
   (i) \( m(\Omega) = 1 \);
   
   (ii) if \( a_i \) are mutually disjoint elements of \( C \) then \( m(\bigcup a_i) = \Sigma m(a_i) \).

A quantum probability space is a triple \( (\Omega, C, M) \) where \( C \) is a \( \sigma \)-class of subsets of \( \Omega \) and \( M \) is the set of states on \( C \).

Lemma 2.1. Let \( C \) be a \( \sigma \)-class of subsets of \( \Omega \).
   
   (i) If \( a, b \in C \) and \( a \subset b \), then \( b \setminus a' \in C \).
   
   (ii) If \( a_1, a_2, \ldots \in C \) and \( a_1 \subset a_2 \subset a_3 \subset \ldots \), then \( \bigcup a_i \in C \).
   
   (iii) If \( a_1, a_2, \ldots \in C \) and \( a_1 \supset a_2 \supset a_3 \supset \ldots \), then \( \bigcap a_i \in C \).

Proof. (i) Since \( a \cap b' = \emptyset \) we have that \( a \cup b' \in C \). Hence \( b' \setminus a' = (a \cup b')' \in C \). (ii) By (i) \( a_1 \cap a_1', a_2 \cap a_2', \ldots \in C \). Since these last sets are mutually disjoint we have \( \bigcup a_i = a_1 \cup (a_2 \cap a_1') \cup (a_3 \cap a_2') \cup \ldots \in C \). (iii) This follows from (ii) by complementation.

If \( a \subset b \) we use the notation \( b - a = b \cap a' \). We next show that there is an abundance of states on any \( \sigma \)-class. A state \( m \) is concentrated at a point \( \omega \in \Omega \) if \( m(a) = 1 \) if \( \omega \in a \) and \( m(a) = 0 \) if \( \omega \notin a \).

Lemma 2.2. If \( (\Omega, C, M) \) is a quantum probability space and \( a, b \in C \), then \( a \subset b \) if and only if \( m(a) \leq m(b) \) for all \( m \in M \).

Proof. If \( a \subset b \), then \( b = a \cup (b - a) \) where \( a \) and \( b - a \) are disjoint.

Received by the editors June 26, 1968.

296
Thus $m(b) = m(a) + m(b - a) \geq m(a)$ for all $m \in M$. If $m(a) \leq m(b)$ for all $m \in M$, by considering states concentrated on $a$, we see that $a \subset b$.

The motivation for this theory is, of course, quantum mechanics. Physically $C$ corresponds to a class of quantum mechanical events. In quantum theory the experiments used to verify two events $a, b \in C$ may interfere and it may be meaningless to consider $a$ and $b$ at the same time. However, if $a \cap b = \emptyset$ then there is no danger of interference so we may consider their logical join $a \cup b$, which is why we defined a $\sigma$-class as we did. If $a$ and $b$ are not disjoint, then they may be incompatible in the sense that no experiment can verify $a \cap b$ or $a \cup b$. Motivated by this we say that $a, b \in C$ are compatible (written $a \leftrightarrow b$) if $a \cap b \in C$. Notice that if $a \subset b$ or if $a \cap b = \emptyset$ then $a \leftrightarrow b$.

**Lemma 2.3.** Let $C$ be a $\sigma$-class. (i) If $a, b \in C$ and $a \leftrightarrow b$, then $a \leftrightarrow b'$ and $a \cup b \in C$. (ii) Suppose $a, a_1, a_2, \cdots \in C$, $a \leftrightarrow a_i$, $i = 1, 2, \cdots$, $\bigcup a_i$ and $\bigcup(a \cap a_i) \in C$. Then $a \leftrightarrow \bigcup a_i$.

**Proof.** (i) Since $a \cap b \subset a$ by Lemma 2.1(i), $a - (a \cap b) \in C$. But $a \cap b' = a - (a \cap b)$ so $a \leftrightarrow b'$. Also

$$a \cup b = \left[ a - (a \cap b) \right] \cup (a \cap b) \cup \left[ b - (a \cap b) \right]$$

and since the latter sets are mutually disjoint $a \cup b \in C$.

(ii) By the distributive law $a \cap (\bigcup a_i) = \bigcup(a \cap a_i) \in C$.

A $\sigma$-field of subsets $F$ of a nonempty set $\Omega$ is a class of subsets that satisfies

(i) $\Omega \in F$;

(ii) if $a \in F$, then $a' \in F$;

(iii) if $a_i \in F$, $i = 1, 2, \cdots$, then $\bigcup a_i \in F$.

If (iii) holds for finite unions, $F$ is called a field.

**Lemma 2.4.** A $\sigma$-class $C$ is a $\sigma$-field if and only if all its elements are compatible.

**Proof.** Necessity is trivial. If all the elements of $C$ are compatible then finite unions of elements in $C$ are in $C$ by Lemma 2.3(i). If $a_i$ is a sequence in $C$, then

$$\bigcup a_i = a_1 \cup (a_2 - a_1 \cap a_2) \cup (a_3 - (a_1 \cup a_2) \cap a_3) \cup \cdots \in C.$$
Theorem 2.5. If $F_1$ and $F_2$ are sub $\sigma$-fields of a $\sigma$-class $C$ there is a sub $\sigma$-field containing them if and only if $F_1 \leftrightarrow F_2$.

Proof. Necessity is trivial. For sufficiency let us first assume that $F_1 \leftrightarrow F_2$ and that $F_1$ and $F_2$ have a finite number of elements. Let $\{a_i\}_{i=1}^{p}$ and $\{b_i\}_{i=1}^{p}$ be the distinct nonempty minimal elements of $F_1$ and $F_2$ respectively. Then clearly the $a_i$'s are mutually disjoint (so are the $b_i$'s), and $\cup a_i = \Omega$ (since $b_i = \Omega$). Let $c_{ij} = a_i \cap b_j$, $i = 1, 2, \ldots, p$, $j = 1, 2, \ldots, p$. Clearly the $c_{ij}$'s are mutually disjoint and $\cup_i c_{ij} = \cup(a_i \cap b_j) = a_i \cup \cap b_j = a_i$, $\cup_i c_{ij} = b_j$, and $\cup_i c_{ij} = \Omega$. If $F_1 \cup F_2$ is $\emptyset$ together with all unions of the $c_{ij}$'s then $F_1$, $F_2 \subset F_1 \cup F_2$ and $F_1 \cup F_2$ is a sub $\sigma$-field with a finite number of elements. Now assume that $F_1$ and $F_2$ are arbitrary sub $\sigma$-fields and $F_1 \leftrightarrow F_2$. Let $F = \cup A_1 \cup A_2$ where $A_1$, $A_2$ run over all finite sub $\sigma$-fields such that $A_1 \subset F_1$, $A_2 \subset F_2$. Clearly, $F_1 \subset F$ and $F_2 \subset F$. Now $\emptyset, \Omega \subset F$ and if $a \in F$ then $a' \in F$. If $a, b \in F$ then there is an $A_1, A_2, A_0^1, A_0^2$ such that $a \in A_1 \cup A_2, b \in A_1 \cup A_2$. Letting $A_0^1 = A_1 \cup A_2^0$ and $A_0^2 = A_2 \cup A_2^0$, we see that $a$ and $b$ are in $A_0^1 \cup A_0^2$. Thus $a \leftrightarrow b$, and $a \cup b \in F$. Thus $F$ is a subfield of $C$. The smallest monotone class of sets including $F$ is a $\sigma$-field [2, p. 27] and is included in $C$ by Lemma 2.1.

3. $\sigma$-classes and internal compatibility. Let us now consider some examples.

Example 1. Let $\Omega = \{1, 2, 3, 4, 5, 6\}$ and let $C$ be the class of subsets of $\Omega$ with an even number of elements. Then $C$ is a $\sigma$-class of subsets but is not a $\sigma$-field since $\{1, 2\} \cap \{2, 3\} = \emptyset \notin C$, for instance. We thus see, of course, that $\{1, 2\} \leftrightarrow \{2, 3\}$.

We have seen in Theorem 2.5 that if $F_1$ and $F_2$ are compatible sub $\sigma$-fields of a $\sigma$-class then they are contained in a common sub $\sigma$-field. This result does not hold for three sub $\sigma$-fields, as the next example shows.

Example 2. Let $\Omega = \{1, 2, \ldots, 8\}$ and let $C$ be the class of subsets of $\Omega$ with an even number of elements. Then again $C$ is a $\sigma$-class but not a $\sigma$-field. Let $a = \{1, 2, 3, 4\}$, $b = \{1, 2, 5, 6\}$, and $c = \{1, 3, 6, 8\}$. Then $a$, $b$, and $c$ are mutually compatible and are thus contained in three mutually compatible sub $\sigma$-fields $F_1$, $F_2$, and $F_3$ respectively. However, we see that $a \cup b \leftrightarrow c$ and hence there is no sub $\sigma$-field containing $F_1$, $F_2$, and $F_3$.

We can get around the difficulty in Example 2 by making the following definition. If $\Omega$ is a nonempty set, a $\sigma$-class ($\sigma$ is for compatibility) $C$ of subsets of $\Omega$ is a $\sigma$-class which satisfies the following: If $a$, $b$, $c$ are mutually compatible sets in $C$, then $c \leftrightarrow a \cup b$. From the physical point of view it is reasonable to assume that quantum events
satisfy this postulate. One can show that the \( \sigma \)-class in Example 1 is a \( c \)-class but clearly the \( \sigma \)-class in Example 2 is not. Of course a \( \sigma \)-field is a \( c \)-class. As we shall see \( c \)-classes are much better behaved than \( \sigma \)-classes.

If \( C \) is a \( \sigma \)-class and \( A \subseteq C \), then the \textit{compatant} of \( A \) is \( A^* = \{ b \in C : b \leftrightarrow a \text{ for all } a \in A \} \). Clearly \( A_1 \subseteq A_2 \) implies \( A_2^* \subseteq A_1^* \). Denoting \( (A^*)^* \) by \( A^{**} \) it is clear that \( A \subseteq A^{**} \). A set \( A \subseteq C \) is \textit{compatible} if the elements of \( A \) are mutually compatible and obviously \( A \subseteq A^* \) if and only if \( A \) is compatible.

**Theorem 3.1.** Let \( C \) be a \( \sigma \)-class in \( \Omega \). Every compatible subset of \( C \) is contained in a sub \( \sigma \)-field if and only if \( C \) is a \( c \)-class.

**Proof.** Necessity is trivial. To prove sufficiency suppose \( C \) is a \( c \)-class and \( A \subseteq C \) is compatible. Since \( A \subseteq A^{**} \), it suffices to show that \( A^{**} \) is a sub \( \sigma \)-field. Obviously \( \emptyset, \Omega \subseteq A^{**} \) and if \( a \in A^{**} \) then \( a^* \in A^{**} \). Now since \( A \subseteq A^* \) we have that \( A^{**} \subseteq (A^{**})^* \) and thus \( A^{**} \) is compatible. Let \( a_i \) be a sequence of elements of \( A^{**} \). As in the proof of Lemma 2.4, \( \bigcup a_i \subseteq C \) (here we use the fact that \( C \) is a \( c \)-class). If \( b \in A^* \), then \( b \leftrightarrow a_i \), \( i = 1, 2, \ldots \), and since \( b \cap a_i \leftrightarrow b \cap a_j \) we have \( \bigcup (b \cap a_i) \subseteq C \) as in the previous sentence. Hence by Lemma 2.3(ii), \( b \leftrightarrow \bigcup a_i \) and \( \bigcup a_i \subseteq A^{**} \) which completes the proof.

**Corollary 3.2** If \( C \) is a \( c \)-class and \( \{ F_i \} \) a collection of mutually compatible sub \( \sigma \)-fields, then \( \bigcup F_i \) is contained in a sub \( \sigma \)-field.

One might expect, in view of Theorem 3.1 and Lemma 2.4, that if we had some compatible elements in a \( c \)-class then the smallest sub \( c \)-class containing these elements would be a sub \( \sigma \)-field. (Or the corresponding statement about two sub \( \sigma \)-fields in a \( \sigma \)-class.) However, these statements are not true. For instance, consider Example 1. Let \( C_1 \) be the class of all subsets of \( \Omega \) and let \( C \) be the \( \sigma \)-class of that example. Then the elements of \( C \) are certainly compatible relative to \( C_1 \), however the smallest sub \( c \)-class containing \( C \) is \( C_1 \) itself which is certainly not a sub \( \sigma \)-field of \( C_1 \).

The previous paragraph emphasizes the fact that compatibility is defined relative to a certain \( \sigma \)-class and that elements compatible relative to one \( \sigma \)-class obviously need not be compatible relative to another. This is not the case, however, in the following situation. A class of subsets \( A \) of a nonempty set \( \Omega \) is \textit{internally compatible} if \( a \cap b \in A \) for all \( a, b \in A \). Thus if \( A \) is internally compatible it is compatible relative to any \( \sigma \)-class containing it.

**Corollary 3.3.** If \( A \) is internally compatible then the \( c \)-class \( C \) generated by \( A \) (i.e. the smallest \( c \)-class containing \( A \)) is a \( \sigma \)-field.
Proof. Since \( A \) is compatible relative to \( C \), applying Theorem 3.1 there is a sub \( \sigma \)-field \( F \) containing \( A \). But \( F \) is a \( c \)-class and by the minimality of \( C \) we have \( C = F \).

Corollary 3.3 does not hold if we replace the word \( c \)-class by \( \sigma \)-class. Indeed, in Example 2, let \( A = \{ a, b, c, \{ 1, 2 \}, \{ 1, 3 \}, \{ 1, 6 \}, \{ 1 \} \} \). Then \( A \) is internally compatible and \( C \) in Example 2 is a \( \sigma \)-class containing \( A \). Hence the \( \sigma \)-class \( C_1 \) generated by \( A \) is contained in \( C \). But since \( c \cap (a \cup b) \notin C \) then \( c \cap (a \cup b) \notin C_1 \) and hence \( C_1 \) cannot be a \( \sigma \)-field.

We now give an application of Corollary 3.3. Let \( \Omega \) be a topological space and let \( A \) be the class of open subsets of \( \Omega \). Since the intersection of two open sets is open, \( A \) is internally compatible. Hence the \( \sigma \)-class generated by \( A \) is a \( \sigma \)-field which is the usual Borel field. Thus in topological spaces if one wants to consider all the open sets then nothing new is gained by using \( c \)-classes. The author does not know whether the \( \sigma \)-class \( C \) generated by \( A \) is the Borel field, although \( C \), of course, is contained in it. However, \( C \) is certainly quite large. For example, if \( \Omega \) is the real line \( R \) then it is easily seen that \( C \) contains all the \( G \)-s and \( F \)-s and thus \( C \) differs from the Borel field at most by sets of Lebesgue measure zero.

4. Observables. Let us now consider what corresponds in this theory to measurable functions. If \( (\Omega, C, M) \) is a quantum probability space, a real valued function \( f : \Omega \to R \) is observable if \( f^{-1}(E) \in C \) for every set \( E \) in the Borel field \( B(R) \). Observable functions are called observables. If \( f \) is observable we use the notation \( A_f = \{ f^{-1}(E) : E \in B(R) \} \). It is easily seen that \( A_f \) is a \( \sigma \)-field. We say that two observables \( f \) and \( g \) are compatible (written \( f \leftrightarrow g \)) if \( A_f \leftrightarrow A_g \). It is clear that if \( g \) is a real Borel function and \( f \) an observable then \( g \circ f \) is observable. Also if \( f_1 \leftrightarrow f_2 \) and \( g_1, g_2 \) are real Borel functions, then \( g_1 \circ f_1 \leftrightarrow g_2 \circ f_2 \).

Theorem 4.1. Let \( C \) be a \( \sigma \)-class. (i) If \( a, b \in C \), then \( a \leftrightarrow b \) if and only if there is an observable \( f \) such that \( a, b \in A_f \). (ii) If \( f \) and \( g \) are observable and \( f \leftrightarrow g \), then \( f + g \) and \( f \cdot g \) are observable. (iii) \( C \) is a \( \sigma \)-field if and only if the sum of any two observables is observable.

Proof. (i) If \( f \) is observable and \( a, b \in A_f \), then \( a \leftrightarrow b \) since \( A_f \) is a sub \( \sigma \)-field. If \( a \leftrightarrow b \) define the function \( f \) by \( f(\omega) = 0 \) for \( \omega \in a \cap b \), \( f(\omega) = 1 \) for \( \omega \in a - a \cap b \), \( f(\omega) = 2 \) for \( \omega \in b - a \cap b \), and \( f(\omega) = 3 \) for \( \omega \in a' \cap b' \). Then \( f \) is observable and \( a = f^{-1}(\{ 0, 1 \}) \), \( b = f^{-1}(\{ 0, 2 \}) \) and hence \( a, b \in A_f \). (ii) Since \( f \leftrightarrow g \), we have \( A_f \leftrightarrow A_g \). By Theorem 2.5 \( A_f \cup A_g \) is contained in a sub \( \sigma \)-field and the result follows from the usual measure theoretic argument. (iii) If \( C \) is a \( \sigma \)-field, then all ob-
servables are mutually compatible and the result follows from (ii).
Now suppose the sum of any two observables is observable and
\( a, b \in C \). If \( \chi_a \) and \( \chi_b \) denote the characteristic functions of \( a \) and
\( b \) respectively then, \( \chi_a + \chi_b \) is observable and hence \( a \cap b = (\chi_a + \chi_b)^{-1}(\{2\}) \subseteq C \). Thus \( a \leftrightarrow b \) and by Lemma 2.4 \( C \) is a \( \sigma \)-field.

It follows from Theorem 4.1 that the sum of two noncompatible
observables need not be observable. However, there are noncom-
patible observables whose sums are observable. For instance, in
Example 1 define the functions \( f \) and \( g \) by \( f(1) = f(2) = 0, f(3) = f(4) = 1, 
\( f(5) = f(6) = 2; \ g(1) = g(6) = 1, \ g(2) = g(4) = 2, \ g(3) = g(5) = 0 \). Then 
\( f \leftrightarrow g \) since \( f^{-1}(\{0\}) \cap g^{-1}(\{1\}) = \{1\} \subseteq C \) for instance. Now it is easy
to check that \( f + g \) and \( f \cdot g \) are observable. However, \( f - g \) is not observ-
able! Notice also that \( f + g \) and \( f \cdot g \) are not compatible with \( f \) or \( g \).
This type of behavior cannot occur with characteristic functions.

**Lemma 4.2.** If \( C \) is a \( \sigma \)-class and \( a, b \in C \), then the following statements
are equivalent, (i) \( a \leftrightarrow b \); (ii) \( \chi_a \leftrightarrow \chi_b \); (iii) \( \chi_a + \chi_b \) is observable; (iv)
\( \chi_a \cdot \chi_b \) is observable; (v) \( \chi_a - \chi_b \) is observable.

We leave the simple proof to the reader.

Let us now briefly consider integration in this theory. If \( f \) is observ-
able and \( m \) a state then \( A_f \) is a \( \sigma \)-field and \( m \) is a measure on \( A_f \). Thus 
\( (\Omega, A_f, m) \) becomes an ordinary probability space and we can define
the integral \( \int fdm \) in the usual way.

**Lemma 4.3.** If \( f \) and \( g \) are (not necessarily compatible) bounded ob-
servables and \( \int fdm = \int gdm \) for every state \( m \), then \( f = g \).

**Proof.** If \( m \) is concentrated at a point \( \omega_0 \) and \( s \) is a simple function,
it follows that \( \int sdm = s(\omega_0) \). Since \( f \) is a limit of simple functions we see that \( \int fdm = f(\omega_0) \).

We thus see that bounded observables satisfy the uniqueness con-
dered in [1]. Another natural question is whether integration is linear. That is, does \( \int (f+g)dm = \int fdm + \int gdm \) for \( f, g \) bounded
observables whose sum is observable and \( m \) any state? The author
does not know the answer to this question; however, it is trivial that
the answer is affirmative for states concentrated at points. The an-
swer is also affirmative if \( f \) and \( g \) are simple functions.

5. Comparison with Mackey's theory. Let us now compare our
theory to that given by Mackey [3] in his axiomatic development of
quantum mechanics. In the sequel we will always assume \( C \) is a
\( \sigma \)-class. Now \( C \) may be regarded as a complemented partially ordered
set in which we define $a \leq b$ if $a \subset b$ and use the usual set complementation. The sup and inf $a \lor b$, $a \land b$, respectively, are defined in the usual way relative to $C$. Note however that $a \lor b$ ($a \land b$) need not equal $a \cup b$ ($a \cap b$) even if the former exist. (They are equal if the latter are in $C$.) For instance, in Example 1 $\{1, 2\} \land \{2, 3\} = \emptyset$ while $\{1, 2\} \cap \{2, 3\} = \{2\} \neq \emptyset$. This also shows that if $a \land b = \emptyset$ then $a$ and $b$ need not be disjoint ($a \cap b = \emptyset$). Thus $a \leftrightarrow b$ is not equivalent to $a \land b \in C$ although the former does imply the latter. We say that $a, b \in C$ split if there exist mutually disjoint elements $a_1, b_1, c \in C$ such that $a = a_1 \lor c$ and $b = b_1 \lor c$. Mackey calls this simultaneous answerability and it corresponds to our notion of compatibility.

**Theorem 5.1.** Suppose $a, b \in C$. (i) If $a \leftrightarrow b$ then $a \lor b = a \cup b$ and $a \land b = a \cap b$. (ii) $a \leftrightarrow b$ if and only if $a$ and $b$ split.

**Proof.** (i) If $a \leftrightarrow b$ then $a \cap b \in C$ and then clearly $a \lor b = a \land b$. (ii) Suppose $a$ and $b$ split and $a = a_1 \lor c$, $b = b_1 \lor c$ where $a_1, b_1 c$ are mutually disjoint elements of $C$. By (i) $a = a_1 \cup c$ and $b = b_1 \cup c$. Thus $c \subset a \lor b$. If $a \cap b = \emptyset$ we are finished. Otherwise suppose $\omega \in a \cap b$. Then $\omega \in c$ or $\omega \in b_1$. Suppose $\omega \in b_1$. Then $\omega \in c$, $\omega \in a_1$ and hence $\omega \in a$, a contradiction. Hence $a \land b = c \in C$ and $a \leftrightarrow b$. Conversely, if $a \leftrightarrow b$ then $a \land b \in C$ and $a - a \cap b$, $b - a \cap b \in C$. Thus $a = (a - a \cap b) \lor (a \cap b)$ and $b = (b - a \cap b) \lor (a \cap b)$.

Using this theorem we see that our language can be translated into the language in Mackey's theory and that our Theorems 2.5, 4.1(i) and 3.1 are related to the results of Varadarajan [6], [7], and Pool [4] respectively. It is left to the reader to find the exact relation between these theories.
