

## TAMENESS IMPLIED BY EXTENDING A HOMEOMORPHISM TO A POINT

L. D. LOVELAND<sup>1</sup>

A 2-sphere is a homeomorphic image of the unit sphere  $B$  defined in  $E^3$  by the equation  $x^2 + y^2 + z^2 = 1$ . A 2-sphere  $S$  is defined to be *tame* in  $E^3$  if there exists a homeomorphism of  $S$  onto  $B$  that can be extended to a homeomorphism of  $E^3$  onto itself. Stated another way,  $S$  is tame if some homeomorphism of  $E^3 - S$  onto  $E^3 - B$  exists that can be extended to take  $S$  onto  $B$ . The main result in this note states that  $S$  is tame if, for each point  $p$  of  $S$ , a homeomorphism  $h$  of  $E^3 - S$  onto  $E^3 - B$  exists such that  $h$  extends to take  $p$  onto some point  $b \in B$ . Actually such a homeomorphism need exist only for each point of a subset of  $S$  whose complement in  $S$  is a closed 0-dimensional set.

The above condition can also be used to characterize "one sided" tameness; that is, a crumpled cube  $C$  is a 3-cell if and only if for each point  $p$  of  $\text{Bd } C$  there exists a point  $b \in B$  and a homeomorphism  $h$  of  $\text{Int } C \cup p$  onto  $\text{Int } B \cup b$ . In this case such a homeomorphism need exist only for the piercing points of  $C$ . Perhaps of interest in this respect are those crumpled cubes  $C$  in  $E^3$  having the property that  $\text{Bd } C$  is locally tame from  $\text{Int } C$  modulo a 0-dimensional set  $W$  of points where  $\text{Bd } C$  is wild from  $\text{Int } C$ . Such an example has been described by Fox and Artin [7]. In case  $W$  consists of a point  $p$  it can be deduced from a result by Doyle and Hocking [6] that no homeomorphism exists between  $\text{Int } C \cup q$  and  $\text{Int } B \cup b$  as long as  $q \neq p$  ( $b \in B$ ). It follows from Theorem 2 that no such homeomorphism exists for any point of  $\text{Bd } C$ .

We also show that  $S$  is tame if for each  $p$  in  $S$  and for each  $\epsilon > 0$  there exist an  $\epsilon$ -disk  $D$  on  $S$  containing  $p$  and a homeomorphism  $h$  of  $E^3 - S$  onto  $E^3 - B$  such that  $h$  extends to take the boundary of  $D$  homeomorphically into  $B$ . For example this means that  $S$  is tame if it has a curvilinear triangulation  $T$  of arbitrarily small mesh such that some homeomorphism of  $E^3 - S$  onto  $E^3 - B$  can be extended to take the 1-skeleton of  $T$  homeomorphically into  $B$ .

Doyle and Hocking [6] have defined a  $K - R$  3-manifold  $M$  to be a 3-manifold-with-boundary such that  $\text{Int } M$  and  $\text{Bd } M$  are topologically  $E^3$  and  $E^2$ , respectively. Suppose that  $M^2$  is a closed topo-

logical plane in a 3-manifold  $M^3$  and  $U$  is a component of  $M^3 - M^2$ . It follows from Corollary 2 that  $M^2 \cup U$  is a  $K-R$  manifold if, for each point  $p \in M^2$ ,  $U \cup p$  is topologically  $\text{Int } B \cup b$  ( $b \in B$ ). Furthermore, applying [6] we see that the  $K-R$  manifold  $M^2 \cup U$  is topologically  $E^2 \times [0, 1)$ .

In the following definitions and in Lemma 1,  $V$  denotes a component of  $E^3 - S$  and  $p$  denotes a point of  $S$ . A point set  $V$  is called an *open 3-cell* if  $V$  is homeomorphic to  $\text{Int } B$ . An  $\epsilon$ -set is a set having diameter less than the positive number  $\epsilon$ . A 2-sphere  $S$  is said to be *locally  $\alpha$ -capped in  $V$  at  $p$*  if for each  $\epsilon > 0$  there exists an  $\epsilon$ -disk  $R$  on  $S$  such that  $p \in \text{Int } R$  and for each  $\alpha > 0$  there is an open  $\epsilon$ -disk  $D$  in  $V \cap N(S, \alpha)$  such that  $\text{Bd } D$  lies in  $S - R$  and  $R$  lies on the boundary of an  $\epsilon$ -component of  $V - D$ . The following lemma is easily proved and appears as Theorem 1 of [10].

LEMMA 1. *If  $S$  is locally  $\alpha$ -capped in  $V$  at  $p$ , then  $V$  is locally simply connected at  $p$ .*

THEOREM 1. *If  $p$  is a point of  $S$  and there exists a homeomorphism of  $\text{Int } S \cup p$  onto  $\text{Int } B \cup b$  ( $b \in B$ ), then  $\text{Int } S$  is locally simply connected at  $p$ .*

PROOF. We shall show that  $S$  is locally  $\alpha$ -capped in  $\text{Int } S$  at  $p$  and then rely on Lemma 1 to complete the proof. Let  $\epsilon > 0$ , let  $U$  be an  $\epsilon/2$ -neighborhood of  $p$  restricted to  $\text{Int } S \cup p$ , and let  $h$  be a homeomorphism as given in the hypothesis. There is a disk  $E$  in  $B$  such that  $h(p) \in \text{Int } E \subset E \subset \text{cl}(h(U))$  and  $E \cap \text{cl}(\text{Int } B - h(U)) = \emptyset$  (otherwise some sequence  $\{h(p_i)\}$  of points in  $\text{Int } B - h(U)$  converges to  $h(p)$  without  $\{p_i\}$  converging to  $p$ ). Let  $I$  be the unit interval  $[0, 1]$ . Since  $B \cup \text{Int } B$  is a 3-cell, there exists a homeomorphism  $f$  of  $E \times I$  into  $B \cup \text{Int } B$  such that  $f(E \times 0) = E$  and  $f(E \times (0, 1)) \subset h(U)$ . Let  $A'$  be the open annulus  $f(\text{Bd } E \times (0, 1))$  and let  $A = h^{-1}(A')$ . Then  $A \subset U$  and one component  $M$  of  $\text{Bd } A$  lies in  $S - p$ . Select a disk  $R$  such that  $p \in \text{Int } R \subset R \subset S - M$ , and let  $\alpha > 0$ . If  $H$  is the set of all points of  $\text{Int } S$  within  $\alpha$  of  $S$ , then  $h(H)$  contains  $f(E \times (0, t))$  for some  $t$  such that  $0 < t < 1$ . Let  $D'$  be the open disk  $f(\text{Bd } E \times (0, t)) \cup f(E \times t)$ . Then  $D = h^{-1}(D')$  is an open  $\epsilon$ -disk in  $N(S, \alpha)$  such that  $\text{Bd } D = M \subset S - R$ . Certainly  $R$  lies on the boundary of an  $\epsilon$ -component of  $\text{Int } S - D$ , so  $S$  is locally  $\alpha$ -capped in  $\text{Int } S$  at  $p$ .

COROLLARY 1. *Suppose  $M$  is a compact connected 2-manifold that separates a connected 3-manifold  $M^3$ ,  $U$  is a component of  $M^3 - M$ , and  $K$  is a polyhedral homeomorphic image of  $M$  in  $M^3$ . If there is a component  $V$  of  $M^3 - K$  such that, for each  $p \in M$ , a point  $b \in K$  and a homeomorphism taking  $U \cup p$  onto  $V \cup b$  exist, then  $M$  is tame from  $U$ .*

PROOF. The proof given for Theorem 1 is not only valid for 2-spheres but will also hold for 2-manifolds as in the hypothesis. Thus  $U$  is locally simply connected at each point of  $M$ , and it follows from [2] that  $M$  is tame from  $U$ .

REMARK. In case  $M$  is a 2-sphere Corollary 1 can be improved somewhat by weakening the hypothesis. We proceed toward an improved version, Theorem 3 to follow, by establishing Lemma 2 and Theorem 2 below. Corollary 2 seems of interest relative to  $K-R$  manifolds as defined in [6].

COROLLARY 2. *Suppose  $M$  is a closed topological plane in a 3-manifold  $M^3$  and  $U$  is a component of  $M^3 - M$ . If, for each  $p \in M$ , a homeomorphism exists taking  $U \cup p$  onto  $\text{Int } B \cup b$  ( $b \in B$ ), then  $M \cup U$  is homeomorphic to  $E^2 \times [0, 1)$ .*

PROOF. As shown in the proof of Theorem 1  $U$  is locally simply connected at each  $p \in M$ . Thus  $M \cup U$  is a 3-manifold with boundary [2]. Now it follows from the corollary in [6] that the  $K-R$  manifold  $M \cup U$  is topologically  $E^2 \times [0, 1)$ .

LEMMA 2. *Suppose a 2-sphere  $S$  in  $E^3$  is locally tame from  $\text{Int } S$  modulo a 0-dimensional set  $W$  and some point  $q$  in  $S - W$  has the following property: There exists an arc  $A$  and a sequence  $\{S_i\}$  of 2-spheres converging to  $S$  such that, for each  $i$ ,  $S_i \subset \text{Int } S$ ,  $S_i \cap A$  is a point at which  $A$  pierces  $S_i$ ,  $q$  is an endpoint of  $A$ , and  $S \cap A = \{q\}$ . Then  $S$  is tame from  $\text{Int } S$ .*

PROOF. Since  $\text{Int } S$  is an open 3-cell,  $S$  is locally tame from  $\text{Int } S$  modulo one point  $p$  [5]. We shall show that  $S$  can be locally spanned from  $\text{Int } S$  at  $p$  and then apply the results of [4] to conclude that  $S$  is tame from  $\text{Int } S$ . There is some resemblance between our proof and the proof given for Theorem 1 in [5].

Let  $\epsilon > 0$  and choose  $\delta$  such that  $0 < 7\delta < \epsilon$  and  $\delta < d(p, A)$ . There exists a disk  $R$ , a locally polyhedral annulus  $B$ , and a simple closed curve  $J$  such that  $p \in \text{Int } R \subset S$ ,  $\text{Bd } R \subset B$ ,  $B - \text{Bd } R \subset \text{Int } S$ ,  $\text{Diam } (B \cup R) < \delta$ ,  $J \cap S = \{p, q\}$ ,  $J \cap B = \emptyset$ ,  $A \subset J$ , and  $J$  pierces  $S$  at both  $p$  and  $q$ . Let  $J_1 = \text{Bd } B - \text{Bd } R$ . There is a 3-cell  $K$  such that  $J_1 \subset \text{Int } K \subset \text{Int } S$ , there is an annulus  $B' \subset B$  such that  $\text{Bd } R \subset \text{Bd } B'$  and  $B' \cap K = \emptyset$ , and there is a subarc  $F$  of  $J$  such that  $p \in \text{Bd } F$ ,  $F - p \subset \text{Int } S$ ,  $F \cap K = \emptyset$ , and  $\text{Diam } F < \delta$ . Using the hypothesis, we choose a polyhedral 2-sphere  $S'$  in  $\text{Int } S$  such that  $S' \cap (J - A) \subset F$ ,  $K \subset \text{Int } S'$ ,  $S' \cap B \subset B'$ ,  $S' \cap A$  is a point,

- (1)  $S' \subset N(S, \delta)$ , and
- (2)  $d(x, S) < d(K, S)$  for all  $x \in S'$ .

We also assume that  $S' \cap B'$  consists of a finite collection of disjoint simple closed curves  $L_1, L_2, \dots, L_n$  no one of which can be contracted in  $B$ . Then each  $L_i$  bounds a disk  $E_i$  on  $S'$  where  $E_i \cap A = \emptyset$ . We choose an integer  $k$  such that  $\text{Int } E_k$  contains no  $L_i$ . Then  $L_k$  and  $\text{Bd } R$  bound an annulus  $B''$  on  $B'$  such that  $B'' \cup E_k$  is a disk  $D$  lying, except for its boundary  $\text{Bd } R$ , in  $\text{Int } S$ . Notice that  $D \cap (K \cup A) = \emptyset$ . In the next paragraph we complete the proof by showing  $\text{diam } D < \epsilon$ .

Let  $E_k = E$ . Since  $J$  links  $\text{Bd } E$  there exists a point  $a \in J \cap \text{Int } E$ . From the construction we see that  $a \in F$ , so  $d(p, a) < \delta$ . Suppose  $\text{Diam } E$  is greater than  $6\delta$ . Then some point  $b \in \text{Int } E$  exists such that  $d(a, b) > 3\delta$  and there is an arc  $ab$  from  $a$  to  $b$  in  $\text{Int } E$ . It follows from (1) and (2) that there exists a point  $c \in S$  such that the segment  $bc$  does not intersect  $K \cup B \cup R$  and  $d(b, c) < \delta$ . The union of a subarc of  $F$  from  $p$  to  $a$ ,  $ab$ ,  $bc$ , and an open arc in  $\text{Ext } S$  from  $c$  to  $p$  is a simple closed curve  $J'$  such that  $J' \cap B = \emptyset$ ,  $J' \subset E^3 - K$ , and  $J'$  links  $\text{Bd } R$ . This means that  $J'$  links  $J_1$  [1]; however, this is a contradiction since  $J_1$  can be contracted in the 3-cell  $K$ . Hence  $\text{Diam } E \leq 6\delta$ . Since  $\text{Diam } B'' < \delta$ , we know that  $\text{Diam } D < 7\delta < \epsilon$ .

**THEOREM 2.** *Suppose that  $S$  is a 2-sphere in  $E^3$  such that the set  $W$  of points where  $S$  is wild from  $\text{Int } S$  is 0-dimensional. If for some point  $q \in S$  there exists a homeomorphism  $h$  of  $\text{Int } S \cup q$  onto  $\text{Int } B \cup b$  ( $b \in B$ ), then  $S \cup \text{Int } S$  is a 3-cell.*

**PROOF.** It is easy to find an arc  $A'$  and a sequence  $\{S_i'\}$  of round 2-spheres in the range of  $h$  such that their inverse images under  $h$  satisfy the hypothesis of Lemma 2. If  $q \in S - W$ , it follows from Lemma 2 that  $S$  is tame from  $\text{Int } S$ .

If  $q \in W$  then  $S$  is locally tame from  $\text{Int } S$  at each point of  $S - q$  [5]. That  $S$  is locally tame from  $\text{Int } S$  in this case follows from Theorem 1 and [2].

**THEOREM 3.** *If there exists a closed 0-dimensional subset  $G$  of a 2-sphere  $S$  such that, for each point  $p \in S - G$ , there exists a homeomorphism of  $p \cup \text{Int } S$  onto  $b \cup \text{Int } B$ , then  $S \cup \text{Int } S$  is a 3-cell.*

**PROOF.** Since  $S - G$  is open it follows from Theorem 1 and [2] that  $S$  is locally tame from  $\text{Int } S$  at each point of  $S - G$ . Thus Theorem 3 follows from Theorem 2.

A point  $p$  of a 2-sphere  $S$  has been called a *piercing point of the crumpled cube*  $C = S \cup \text{Int } S$  if and only if there is a homeomorphism  $h$  of  $C$  into  $E^3$  such that  $h(S)$  can be pierced at  $h(p)$  by a tame arc [13].

**COROLLARY 3.** *If  $S$  is a 2-sphere in  $E^3$  such that, for each piercing point  $p$  of  $S \cup \text{Int } S$ , there exists a homeomorphism of  $\text{Int } S \cup p$  onto  $\text{Int } B \cup b$  ( $b \in B$ ), then  $S \cup \text{Int } S$  is a 3-cell.*

**PROOF.** From the fact that  $S \cup \text{Int } S$  has piercing points [13] and the hypothesis, we see that  $\text{Int } S$  is an open 3-cell. Then  $S \cup \text{Int } S$  has at most one nonpiercing point (see [11] or [14]), so Corollary 3 follows from Theorem 3.

**THEOREM 4.** *If there is a closed 0-dimensional subset  $G$  of a 2-sphere  $S$  such that for each  $p \in S - G$  there exists a homeomorphism of  $(E^3 - S) \cup p$  onto  $(E^3 - B) \cup b$ , then  $S$  is tame.*

**PROOF.** We may think of  $S$  as lying in  $S^3$  so that it follows from Theorem 3 that  $S$  bounds two 3-cells in  $S^3$ . Thus  $S$  is tame.

**COROLLARY 4.** *If  $S$  is a 2-sphere in  $E^3$  such that, for each point  $p$  of  $S$  that lies in a tame arc on  $S$ , there exists a homeomorphism of  $(E^3 - S) \cup p$  onto  $(E^3 - B) \cup b$ , then  $S$  is tame.*

**PROOF.** Corollary 4 follows from Theorem 4 because at most two points of  $S$  fail to lie in tame arcs in  $S$  (see [8] and [11] or [14]).

**THEOREM 5.** *Let  $S$  be a 2-sphere in  $E^3$  and let  $\epsilon > 0$ . If for each  $p \in S$  there exist an  $\epsilon$ -disk  $D$  in  $S$  containing  $p$  and a homeomorphism  $h$  of  $\text{Int } S$  onto  $\text{Int } B$  such that  $h$  extends to take  $\text{Bd } D$  homeomorphically into  $B$ , then  $S \cup \text{Int } S$  is a 3-cell.*

**PROOF.** Let  $p \in S$  and notice that  $\text{Int } S$  is locally simply connected at  $p$  if  $p$  lies in the boundary of some disk  $D$  as given in the hypothesis (see Theorem 1). Otherwise  $p$  lies in the interiors of arbitrarily small such disks, and we are able to prove that  $S$  is locally  $\alpha$ -capped from  $\text{Int } S$  at  $p$ . Once this is done we rely on Lemma 1 and [2] to complete the proof.

Let  $U$  be an open set containing  $p$ , let  $D$  be a disk such that  $p \in \text{Int } D \subset D \subset U \cap S$ , and let  $h$  be a homeomorphism of  $\text{Int } S$  onto  $\text{Int } B$  that extends to take  $\text{Bd } D$  homeomorphically into  $B$ . As in the proof of Theorem 1, we choose a disk  $E'$  in  $h(U \cap \text{Int } S) \cup h(\text{Bd } D)$  such that  $\text{Bd } E' = h(\text{Bd } D)$ , and we let  $E = h^{-1}(E')$ . Such a disk  $E$  can be chosen in any neighborhood of  $S$ , so  $S$  is locally  $\alpha$ -capped from  $\text{Int } S$  at  $p$ .

**THEOREM 6.** *If for each point  $p$  of a closed subset  $F$  of a 2-sphere  $S$  in  $E^3$  there exists a homeomorphism  $h$  of  $\text{Int } S \cup p$  onto  $\text{Int } B \cup b$ , then  $F$  lies on the boundary of a 3-cell.*

PROOF. From Theorem 1 we see that  $\text{Int } S$  is locally simply connected at each point of  $F$ . Now the techniques in the proof of Theorem 1 in [2] can be applied, as indicated in the proof of Theorem 10 of [9], to yield Property  $(*, F, \text{Int } S)$ ; that is,  $S$  can be side approximated from  $\text{Int } S$  missing  $F$  (see [8] or [9] for a precise definition). The reason no restriction is placed on the size of the components of  $F$  in Theorem 6 is that the local simple connectedness of  $\text{Int } S$  at each point of  $F$  is a much stronger hypothesis than that of Theorem 10 of [9]. We omit the tedious details since they are like those of [9]. Once  $(*, F, \text{Int } S)$  is known the conclusion of Theorem 6 follows from [12].

THEOREM 7. *If  $S$  is a 2-sphere in  $E^3$  and  $p$  is a point of  $S$  such that there exists a homeomorphism of  $\text{Int } S \cup p$  onto  $\text{Int } B \cup b$  ( $b \in B$ ), then  $p$  is a piercing point of  $S \cup \text{Int } S$ .*

PROOF. As indicated in the proof of Theorem 6, Property  $(*, p, \text{Int } S)$  can be established. This is sufficient for  $p$  to be a piercing point of  $S \cup \text{Int } S$  [11].

REMARK. Of course the converse to Theorem 7 is false even if  $\text{Int } S$  is an open 3-cell (see Theorem 2 and an appropriate example in [7]).

THEOREM 8. *Suppose  $F$  is a set as given in Theorem 6. If for each point  $p$  of  $F$  there exists a homeomorphism of  $(E^3 - S) \cup p$  onto  $(E^3 - B) \cup b$  ( $b \in B$ ), then  $F$  lies on a tame 2-sphere.*

PROOF. The proof here is much the same as that outlined for Theorem 6. We first obtain Property  $(*, F, S)$ , then we appeal to Theorem 6 of [9].
