AN INVARIANCE PRINCIPLE FOR REVERSED MARTINGALES

R. M. LOYNES

Abstract. Let $X_n$, $n = 1, 2, \ldots$, be a reversed martingale with zero mean and for each $n$ construct a random function $W_n(t)$, $0 \leq t \leq 1$, by a suitable method of interpolation between the values $X_k/(EX_n^2)^{1/2}$ at times $EX_n^2/EX_n^2$; these are the natural times to use. Then it is shown that the distribution of $W_n$ (in function space $C$ or $D$) converges weakly to that of the Wiener process, if the finite-dimensional distributions converge appropriately. It is also shown that the sufficient conditions recently given by the author for the central limit theorem for such martingales also imply convergence of finite-dimensional distributions. Illustrations of the use of these results are given in applications to $U$-statistics and sums of independent random variables.

A result for forward martingales exactly analogous to the first result above is also given, but is given no emphasis.

1. Introduction and summary. It was shown in Loynes [4] that, under suitable conditions, if $\{X_n:n \geq 1\}$ is a reverse martingale there exists a function $\phi(n)$ such that the distribution of $\phi(n)^{1/2}X_n$ converges to $N(0, 1)$ weakly as $n \to \infty$. (For convenience, we take the limit of $X_n$ as 0 in the present paper.)

Under the same conditions, define for each $n$ a random function $W_n(t)$ for $0 \leq t \leq 1$ as follows:

1. $W_n(0) = 0$;
2. $W_n(t_n^k) = \phi(n)^{1/2}X_k$, where $t_n^k = \phi(n)^{-1}\{\phi(k)\}$, for $k \geq n$;
3. $W_n(t) = W_n(t_n^k)$ if $t_{k+1} < t < t_n^k$.

(Condition (3) ensures that $W_n(t)$ is a step-function which is continuous on the left: as in other situations the theorems below would remain true under slight variations in the definition of $W_n$.) Then it will be shown, in Theorem 1, that the finite-dimensional distributions of $W_n$ converge to those of the Wiener process $W$.

In general it is not sufficient, in order to prove weak convergence of the distribution of random functions such as $W_n$ to that of $W$, to prove convergence of the finite-dimensional distributions. It will be
shown in Theorem 2 that in the present case, in which reverse martingales appear, this condition is sufficient provided that \( \phi(n) = [E(X_n^2)]^{-1} \). This rather striking result has an obvious analogue for forward martingales, which is stated as Theorem 3. There is an analogue of Theorem 1 also, but it will not be presented here.

The theorems are stated in §2, after the definitions and notation, and their proofs follow in §§3 and 4. §5 contains some applications.

2. Definitions, notation, and statement of results. The notation will be as in [4]. Thus on a fixed probability space \((\Omega, \mathcal{F}, P)\) we have a sequence of random variables \( X_n \) and a sequence of \( \sigma \)-fields \( \mathcal{G}_n \); in both cases, \( n \geq 1 \). Then for all \( n: \mathcal{G}_n \supseteq \mathcal{G}_{n+1}, \) \( X_n \) is measurable with respect to \( \mathcal{G}_n; \) \( E[|X_n|] < \infty \); \( E(X_n | \mathcal{G}_{n+1}) = X_{n+1} \) with probability 1. We suppose \( X_n \to 0 \) with probability 1, and write

\[
Y_n = X_n - X_{n+1},
\]

\[
\sigma_n^2 = E(Y_n^2 | \mathcal{G}_{n+1}),
\]

and

\[
\sigma_n^2 = \sum_{r=n}^{\infty} \sigma_r^2.
\]

Then it follows that

\[
E(Y_n | \mathcal{G}_{n+1}) = 0,
\]

\[
X_n = \sum_{r=n}^{\infty} Y_r,
\]

and

\[
E(X_n^2) = \sum_{r=n}^{\infty} E(Y_r^2) = ES_n^2.
\]

Now we may state the results: the notation \( W_n \Rightarrow W \) means that the distribution of the random function \( W_n \) converges weakly to that of the Wiener process \( W \) (cf. Billingsley [1, p. 7]).

**Theorem 1.** If (a) \( \phi(n) \sigma_n^2 \to 1 \), for some function \( \phi \) satisfying

\[
\phi(n + 1) \geq \phi(n) \quad \text{and} \quad \phi(n + 1)/\phi(n) \to 1,
\]

and (b) either

\[
\frac{1}{\sigma_n^2} \sum_{r=n}^{\infty} Y_r^2 \to 1
\]

or

\[
\phi(n) E(\sigma_n^2) \to 1
\]

and

\[
\frac{1}{\sigma_n^2} \sum_{r=n}^{\infty} E[Y_r^2 I(|Y_r| > \epsilon \sigma_n) | \mathcal{G}_{r+1}] \to 0 \quad \text{for all } \epsilon > 0,
\]

all convergence being with probability 1, and if \( W_n(t) \) is defined by (1),
(2) and (3), then the finite-dimensional distributions of $W_n(t)$ converge to those of $W(t)$.

**Remark.** In [4], some stronger conditions are given which imply the conditions required here and which are probably simpler to verify in practice.

**Theorem 2.** If $X_n$ is a reversed martingale, and if the finite-dimensional distributions of $W_n$, as defined by (1), (2), and (3) with $\phi(n) = [E(X_n^2)]^{-1}$, converge to those of $W$, then $W_n \Rightarrow W$.

For the next theorem, suppose \{X_n: n \geq 1\} is a forward martingale, and for each $n$ define a random function $W_n(t)$ for $0 \leq t \leq 1$ by

1. $W_n(0) = 0$;
2. $W_n(t_k^n) = \phi(n)^{1/2} X_k$, where $t_k^n = \phi(n) \{\phi(k)\}^{-1}$, for $k \leq n$;
3. $W_n(t) = W_n(t_k^n)$, if $t^k_n < t < t_{k+1}^n$.

**Theorem 3.** If $X_n$ is a (forward) martingale, and if the finite-dimensional distributions of $W_n$, as defined by (10), (11) and (12) with $\phi(n) = [E(X_n^2)]^{-1}$, converge to those of $W$, then $W_n \Rightarrow W$.

Although Theorem 3 would appear to be useful, there seems less need for an analogue to Theorem 1; in any case, none will be given here. The possibility of embedding a forward martingale in a Wiener process, noted by Strassen [6], allows an approach to convergence problems (see Theorem 4.4 of [6]) which is capable of giving much more delicate results. Now one may speculate that a reversed martingale might similarly be embedded: presumably a sequence of stopping-times $0 \leq \cdots \leq T_n \leq \cdots \leq T_1$ would be constructed in such a way that \{W(T_n)\} has the same distribution as \{X_n\}. However, although it is very plausible that such an embedding is possible, and that if it were it would allow an elegant treatment of the present results, it appears that a proof would be difficult, and none has so far been given.

We are therefore thrown back on to more direct methods, of the type described in the recent monograph by Billingsley [1]. A weak convergence result is given there (in §23) for (forward) martingales, but the proof leans heavily on the assumed stationarity, and our proofs will return to first principles.

3. **Proof of Theorem 1.** To prove convergence of the finite-dimensional distributions is rather straightforward, most of the work having already been done in [4]; in view of this, we shall assume familiarity with its contents. We shall consider the joint distribution of $W_n(a)$
and $W_n(b)$ only, where $0 < a < b \leq 1$, but the joint distribution for three or more times can be treated quite similarly. In [4], equation (17) onwards, various quantities are defined as functions of a single variable $t$; we shall need to deal simultaneously with two values $a$ and $b$, since our first aim is to prove that the distribution of $(t^{-1/2}Z_{at}, t^{-1/2}Z_{bt})$ converges weakly to that of $(W(a), W(b))$. We shall, therefore, have two sets of quantities which will be denoted by $m_{at}$, $m_{bt}$, $\bar{Y}_{a,k}$, $\bar{Y}_{b,k}$ and so on: notice that $m_{at} \geq m_{bt}$, so that $\bar{Y}_{ak} = \bar{Y}_{bk}$ if $m_{at} < k$, and that we have $\sum \sigma_{ak}^2 = at$, $\sum \sigma_{bk}^2 = bt$. In the definition of $\eta_n$, a sequence of independent Normal random variables is needed: we choose the same sequence for both $\eta_{an}$ and $\eta_{bn}$. It will be shown that as $t \to 0$

(13)  $E[\exp(iua^{1/2}\eta_{an} + ivb^{1/2}\eta_{bn})] - E[\exp(iua^{1/2}\eta_{an+1} + ivb^{1/2}\eta_{bn+1})] \to 0$: the first term of (13) is the characteristic function of $(t^{-1/2}Z_{at}, t^{-1/2}Z_{bt})$ and the second term tends, as $t \to 0$, to that of $(W(a), W(b))$. (The means and variances of the second term are correct for all $t$, and the distribution is Normal, but the covariance will not in general be exactly equal to $a$ for finite $t$; however, convergence to the correct value as $t \to 0$ is a consequence of the fact that $\sigma_n^2/\sigma_{n+1}^2 \to 0$.) Now following the same argument as in [4], we find

\[
| E(\exp(iua^{1/2}\eta_{an} + ivb^{1/2}\eta_{bn}) - \exp(iua^{1/2}\eta_{an+1} + ivb^{1/2}\eta_{bn+1})) | \leq E \left| E \left\{ \left( \frac{|u| + |v|}{t} \right)^2 \bar{Y}_{bn} \exp \left( \left| u \right| + \left| v \right| \right) t^{-1/2} \right\} \right| \]

(14)

\[
\leq E \left\{ \left( \frac{|u| + |v|}{t} \right)^2 \bar{Y}_{bn} \exp \left( \left| u \right| + \left| v \right| \right) t^{-1/2} \right\} \]

on using the fact that $|\bar{Y}_{an}| \leq |\bar{Y}_{bn}|$, $\sigma_{an}^2 \leq \sigma_{bn}^2$. (Note that (29) of [4] contains two misprints: an exponent is obviously misplaced, and the interior expectation on the right-hand side should be conditional on $\mathcal{G}_{n+1}$.) As the bound obtained in (14) is essentially the same as that entering into (30) of [4], this first part of the proof is complete.

Next we shall show that for fixed $a$ ($0 < a \leq 1$) $W_n(a) - t_n^{-1/2}Z_{at_n} \to 0$ in probability, where $t_n = \phi(n)^{-1}$; from this and the previous results will follow convergence of the finite-dimensional distributions. Observe that $W_n(a) = \phi(n)^{1/2}X_{k(n)}$, where $k(n)$ is an integer such that

(15)  $\phi(n)/\phi(k(n) + 1) < a \leq \phi(n)/\phi(k(n))$. 

License or copyright restrictions may apply to redistribution; see https://www.ams.org/journal-terms-of-use
If we write $m_{atn} = m_{an}$ for convenience, it follows as in (45) of [4] that
\[ \phi(m_{an})/\phi(k(n)) \to 1 \quad \text{with probability 1}, \]
and then the argument used to prove (47) of [4] (in which the suffix of $Z$ should be $t_n$) will complete the proof.

4. Proof of Theorems 2 and 3. According to Theorem 15.1 of Billingsley [1], we have only to show that the sequence $W_n$ is tight, and we can conveniently separate some parts of the proof into preliminary lemmas.

**Lemma 1.** If the finite-dimensional distributions of $W_n$ converge to those of $W$, then
\[ \sup_{k \leq n} \left| \frac{\phi(n)}{\phi(k)} - \frac{\phi(n)}{\phi(k + 1)} \right| \to 0 \quad \text{as } n \to \infty. \]

**Proof.** It is clearly sufficient to show that $\phi(n+1)/\phi(n) \to 1$. Suppose the contrary: then along some subsequence we have $\phi(n)/\phi(n+1) < 1 - \epsilon$ for some $\epsilon > 0$, so that $W_n(1-\epsilon) = W_n(1)$. Thus along this subsequence $P[W_n(1-\epsilon) = W_n(1)] = 1$, which contradicts the hypothesis of the lemma.

**Lemma 2.** If for some random variable $X$, $E(X^2) < \infty$, and $h$ is a function with values in $[0, 1]$ then
\[ E[X^2h(X)] \leq E[X^2\lambda(X)] \]
where
\[ 0 \leq \lambda(x) \leq 1, \quad \text{for all } x, \]
\[ \lambda(x) = 0, \quad |x| < \alpha(h), \]
\[ = 1, \quad |x| > \alpha(h), \]
and $E[\lambda(X)] = E[h(X)]$.

**Proof.** This is an immediate consequence of the Neyman Pearson Lemma. The constant $\alpha(h)$ does of course depend on the distribution of $X$.

We may now begin the main part of the proof of Theorem 2. We shall apply Theorem 15.5 of [1], proving the second condition by applying the Corollary to Theorem 8.3; the first condition is already satisfied. It is sufficient to show that given $\epsilon, \eta, r$ may be chosen to make
\[ p = \sum_{i=1}^{r} P \left[ \sup_{(i-1)/r \leq s \leq i/r} \left| W_n(s) - W_n \left( \frac{i-1}{r} \right) \right| \geq \epsilon \right] < \eta. \]
Let us for convenience write

\begin{equation}
A_r(n, i) = \left\{ \sup_{(i-1)/r \leq s \leq i/r} \left| W_n(s) - W_n \left( \frac{i - 1}{r} \right) \right| \geq \epsilon \right\}
\end{equation}

and

\begin{equation}
Z_r(i, n) = r^{1/2} \{ W_n(i/r) - W_n((i - 1)/r) \}.
\end{equation}

Then for fixed \(i\) and \(r\), \(Z_r(i, n) \Rightarrow N(0, 1)\) by hypothesis, while from Lemma 1 it follows that \(E[Z_r(i, n)^2] \rightarrow 1\), so that if \(n \geq n_r\) (to be chosen suitably) \(E[Z_r(i, n)^2] \leq 2\).

If we apply Theorem 3.2 in Chapter VII of Doob [2], recalling the definition of \(W_n\), we find

\begin{equation}
P(A_r(n, i)) \leq \frac{1}{\epsilon^2 r} \int_{A_r(n, i)} Z_r(i, n)^2 dP
\end{equation}

\begin{equation}
\leq \frac{1}{\epsilon^2 r} E[Z_r(i, n)^2]
\end{equation}

\begin{equation}
\leq \frac{2}{\epsilon^2 r} \text{ if } n \geq n_r.
\end{equation}

According to Lemma 2, we have

\begin{equation}
\int_{A_r(n, i)} Z_r(i, n)^2 dP = E[Z_r(i, n)^2 P\{ A_r(n, i) \mid Z_r(i, n) \}]
\end{equation}

\begin{equation}
\leq E[Z_r(i, n)^2 \lambda(Z_r(i, n))]
\end{equation}

with \(\lambda(x) = 0\) if \(|x| < \alpha_r(i, n)\), \(1\) if \(|x| > \alpha_r(i, n)\), and

\begin{equation}
E[\lambda(Z_r(i, n))] = P\{ A_r(n, i) \}.
\end{equation}

Next choose \(\theta\) so that

\begin{equation}
\int_{|X| \geq \theta} X^2 dP = \eta \epsilon^2/2
\end{equation}

when \(X\) is \(N(0, 1)\), and \(r\) so that

\begin{equation}
2/\epsilon^2 r < 1/3 P[|X| \geq \theta].
\end{equation}

It follows from (19), (21) and (23), since \(Z_r(i, n)\) converges to \(N(0, 1)\), that if \(n\) is sufficiently large \(\theta \leq \alpha_r(i, n)\), for \(1 \leq i \leq r\). Then from (20) we find

\begin{equation}
\int_{A_r(n, i)} Z_r(i, n)^2 dP \leq \int_{|Z_r| \geq \theta} Z_r(i, n)^2 dP,
\end{equation}

License or copyright restrictions may apply to redistribution; see https://www.ams.org/journal-terms-of-use
and because of (22), the convergence of $Z_i(n)$ to $N(0, 1)$, and the convergence of $E[Z_i(n)^2]$ to 1, the right-hand side of (24) is less than $\eta^2$ for sufficiently large $n$. (Compare the argument in [1, p. 33].) But now (16) follows from (19).

The proof of Theorem 3 is almost identical, and will therefore not be given.

5. Applications. Apart from observing that Theorem 3 is especially easy to apply when $X_n$ is the partial sum of independent random variables, and that in particular Donsker's original theorem follows from it, by using the Central Limit Theorem, we shall make no reference to forward martingales.

Three types of reversed martingale were considered in [4]:
(a) $S_n/n$, where $S_n$ is the $n$th partial sum of a sequence of independent identically distributed random variables with mean 0 and variance $\sigma^2 < \infty$;
(b) $U_n$, the $n$th $U$-statistic formed from a given kernel with mean 0 and finite variance;
(c) $R_n = \sum_{r=n}^{\infty} c_r P_r$, where $P_r$ are independent and identically distributed with mean 0 and variance $\sigma^2$, and $c_r^2 = o(\sum_{r=n}^{\infty} c_r^2)$.

(The notation is slightly different from [4].) Both $S_n/n$ and $R_n$ were shown in [4] to satisfy the conditions of the present Theorem 1, and weak convergence for the random functions $W_n$ constructed as in (1), (2) and (3) then follows from Theorem 2. Weak convergence in the case of $U_n$ also follows from Theorem 2, although it has not been shown that the conditions of Theorem 1 are satisfied, for convergence of finite-dimensional distributions follows easily from Hoeffding [3].

If we now apply Theorem 5.1 of [1] with some admissible function $h$, we obtain limit theorems about $S_n/n$, $U_n$, and $R_n$. The following are examples. (The variances of $U_n$ and $R_n$ are denoted by $v_U(n)$ and $v_R(n)$ respectively for brevity.)
(i) $h(x) = \sup \{x(t) : 0 \leq t \leq 1\}$.

**Theorem 4.** Each of

$$P\left[ \sup_{k \geq n} S_k/k \geq n^{-1/2} x\sigma \right], \quad P\left[ \sup_{k \geq n} U_k \geq v_U(n)x \right], \quad P\left[ \sup_{k \geq n} R_k \geq v_R(n)x \right]$$

tends to

$$P\left[ \sup_{0 \leq t \leq 1} W(t) \geq x \right] = 2(1 - \Phi(x)) \quad \text{as} \ n \to \infty,$$
for all $x > 0$, where $\Phi(x)$ is the distribution function of $N(0, 1)$.

From this, Theorem 1 of [5] follows immediately and Theorem 3 is also easy to prove. Similar results may be obtained from $h(x) = \sup \{ |x(t)| : 0 \leq t \leq 1 \}$.

The functionals $h$ used in the next two results are not almost everywhere continuous on $D$, and thus Theorem 2 as stated can not be applied. They are, however, admissible if attention is restricted to $C$, and since as already observed Theorem 2 remains true if the definition of $W_n$ is changed slightly, for example by requiring linear interpolation between successive points $t_k^*$ for fixed $n$, the results are valid.

(ii) $h(x) = \sup \{ t : t \in [0, 1] \text{ and } x(t) = 0 \}$.

For a reversed martingale $X_n$, let us say that a 0-crossing takes place at $i$ if the event

$$E_i = \{ X_i = 0 \} \cup \{ X_{i-1} > 0 > X_i \} \cup \{ X_{i-1} < 0 < X_i \}$$

occurs (cf. Billingsley [1] equation (11.28)). Define $K_n$ with appropriate superfixes as the minimum $\leq n$ for which a 0-crossing takes place at $i$.

**Theorem 5.** Each of

$$P[K_n^S \leq \lambda n], \quad P[v_U(K_n)^{-1} \leq \lambda v_U(n)^{-1}], \quad P[v_R(K_n)^{-1} \leq \lambda v_R(n)^{-1}]$$

tends to $(2/\pi) \arcsin (1/\lambda)^{1/2}$ as $n \to \infty$.

(iii) $h(x) = \inf \{ t : x(t) = \sup_{0 \leq s \leq 1} x(s) \}$.

The results will not be given in detail, but they determine the asymptotic distribution of the largest $k$ for which $X_k = \sup_{j \leq n} X_j$.

One may of course investigate the joint distributions of such quantities, and other choices of $h$ may be made. Because of the nonuniform spacing of the $t_k^*$ for a given $n$ the results are sometimes intuitively less appealing than the corresponding ones for the partial sums derived from the Donsker principle: as an example the choice of $h$ to be the Lebesgue measure of the set of times that $x(t)$ is positive may be cited.

**References**

---

* A referee has pointed out that Theorem 5 at least can be obtained from the stated version of Theorem 2 if $h$ is redefined by

$$h(x) = \sup \{ t : t \in [0, 1] \text{ and } x(t)x(t+) \leq 0 \}.$$
