

## NOTE ON NONNEGATIVE MATRICES

D. Ž. DJOKOVIĆ<sup>1</sup>

ABSTRACT. Let  $A$  be a nonnegative square matrix and  $B = D_1 A D_2$  where  $D_1$  and  $D_2$  are diagonal matrices with positive diagonal entries. Several proofs are known for the following theorem: If  $A$  is fully indecomposable then  $D_1$  and  $D_2$  can be chosen so that  $B$  is doubly stochastic. Moreover,  $D_1$  and  $D_2$  are unique up to a scalar factor. It is shown that these results can be easily obtained by considering a minimum of a certain rational function of several variables.

Several recent papers [1], [2], [3], [4] were devoted to the following problem: Given a nonnegative square matrix  $A$ , find the conditions for the existence of two diagonal matrices  $D_1$  and  $D_2$  such that  $D_1 A D_2$  is doubly stochastic. We shall show that it is related to a simple minimum problem. This leads to a short proof of Theorem (6.1) of [1] which avoids the use of Menon's operator.

We begin with some definitions. An  $n \times n$  ( $n \geq 2$ ) matrix  $A$  is reducible if there exists a permutation matrix  $P$  such that

$$P A P^T = \begin{pmatrix} A_1 & 0 \\ B & A_2 \end{pmatrix}$$

where  $A_1$  is a  $k \times k$  matrix,  $1 \leq k \leq n-1$ . Otherwise we say that  $A$  is irreducible.

An  $n \times n$  ( $n \geq 2$ ) matrix  $A$  is fully indecomposable if there do not exist permutation matrices  $P$  and  $Q$  such that

$$P A Q = \begin{pmatrix} A_1 & 0 \\ B & A_2 \end{pmatrix}$$

where  $A_1$  is a  $k \times k$  matrix,  $1 \leq k \leq n-1$ .

**THEOREM.** *Let  $A$  be a nonnegative  $n \times n$  fully indecomposable matrix. Then there exist diagonal matrices  $D_1$  and  $D_2$  with positive diagonals such that  $D_1 A D_2$  is doubly stochastic. Moreover  $D_1$  and  $D_2$  are uniquely determined up to scalar multiples.*

For the proof we need the following

LEMMA. Let  $A$  be a nonnegative  $n \times n$  matrix. Then  $A$  is fully indecomposable if and only if there exist permutation matrices  $P$  and  $Q$  such that  $PAQ$  has a positive main diagonal and is irreducible.

A short proof of this lemma appears in [1].

PROOF OF THE THEOREM. By the lemma we can assume that  $A = (a_{ij})$  has positive main diagonal and is irreducible. Let

$$f(x_1, \dots, x_n) = \prod_{k=1}^n \left( \sum_{i=1}^n a_{ki} x_i \right) / \prod_{k=1}^n x_k$$

the variables being restricted by

$$(1) \quad x_k > 0 \quad (1 \leq k \leq n), \quad \sum_{k=1}^n x_k = 1.$$

Let  $(b_i)$  be a boundary point of the region (1) and, for instance,  $b_1 = \dots = b_s = 0, b_k > 0 (s < k \leq n)$ . Since  $A$  is irreducible we infer that at least one entry  $a_{ij} > 0$  for  $1 \leq i \leq s, s < j \leq n$ . This implies that  $f(x_1, \dots, x_n) \rightarrow +\infty$  when  $(x_k) \rightarrow (b_k)$ . Therefore  $f$  attains its minimum in some point  $(c_k)$  of the region (1). The partial derivatives of  $f$  vanish at  $(c_k)$  since  $f$  is homogeneous. Hence,

$$\sum_{k=1}^n c_j a_{kj} \left( \sum_{i=1}^n a_{ki} c_i \right)^{-1} = 1 \quad (j = 1, \dots, n)$$

which proves the first assertion of the theorem.

For the uniqueness it is sufficient to prove the following assertion: If the matrices  $X = (x_{ij}), D_1 = \text{diag}(d'_1, \dots, d'_n), D_2 = \text{diag}(d''_1, \dots, d''_n)$  satisfy

(i)  $X$  is irreducible doubly stochastic with positive elements on the main diagonal;

(ii)  $d'_i > 0, d''_i > 0 (1 \leq i \leq n)$ ;

(iii)  $D_1 X D_2$  is doubly stochastic, then  $D_1$  and  $D_2$  are scalar matrices.

Since

$$\sum_{j=1}^n d'_i x_{ij} d''_j = 1 \Rightarrow (\max d'_i)(\min d''_j) \leq 1,$$

$$\sum_{i=1}^n d'_i x_{ij} d''_j = 1 \Rightarrow (\max d'_i)(\min d''_j) \geq 1.$$

we conclude that none of these inequalities is strict. This implies that  $x_{rs} = 0$  whenever  $d'_r = \max d'_i$  and  $d''_s > \min d''_j$  or  $d'_r < \max d'_i$  and  $d''_s = \min d''_j$ . This contradicts (i) unless  $D_1$  and  $D_2$  are scalar matrices.

The proof is completed.
