

AN ADDITIVE DECOMPOSITION THEOREM FOR ANALYTIC FUNCTIONS

DONALD E. MYERS

ABSTRACT. Kraut, Busenberg, and Hall have shown that the uniqueness of the additive decomposition for functions of several variables given by Bochner is due to the asymptotic properties of the summands. In this paper, the uniqueness theorem is used to extend the class of functions possessing unique decompositions.

Recently Kraut, Busenberg and Hall [2] have observed that the asserted uniqueness for additive decompositions of holomorphic functions on tubes in complex n -space as given by Bochner [1] is due to the asymptotic decay of the summands. In this note we will show that [1], [2] actually provide somewhat more general results than are stated. Following [1], a tube T in C^n is of the form $\{z \mid z = (z_1, \dots, z_n), \sigma_i < \Re(z_i) < \mathfrak{J}_i\}$. A tube is said to be octant shaped if for each i either $\sigma_i = -\infty$ or $\mathfrak{J}_i = +\infty$ but not both. As observed in [2], Bochner's hypothesis for a unique decomposition is sufficient and the following theorem shows that it is not necessary.

THEOREM. *Let f be analytic in a tube T and suppose there exists a point $\alpha = (\alpha_1, \dots, \alpha_n)$ not in the closure of the base of T and an n -tuple $\beta = (\beta_1, \dots, \beta_n)$, $0 < \beta_i < 1$, such that*

$$|f(z)| \prod_{i=1}^n |z_i - \alpha_i|^{\beta_i} < M$$

for some positive constant M . Then there exist unique functions f_1, \dots, f_{2^n} each analytic in an octant shaped tube such that $f = f_1 + \dots + f_{2^n}$ in T .

PROOF. Clearly $g(z) = f(z) / \prod_{i=1}^n (z_i - \alpha_i)$ satisfies Bochner's condition of being square integrable with respect to the imaginary part for each z_i . Then $g(z)$ has a decomposition $g = g_1 + \dots + g_{2^n}$ and hence $f = f_1 + \dots + f_{2^n}$ where $f_j(z) = g_j(z) \prod_{i=1}^n (z_i - \alpha_i)$. It is only necessary then to show that each $f_j(z)$ is unique, i.e. independent of $\alpha = (\alpha_1, \dots, \alpha_n)$. By Theorem 1 [2], it is sufficient to show each f_j is

bounded in the octant-shaped tube T_j and $f_j \rightarrow 0$ as any one of the $x_j \rightarrow \pm \infty$ in T_j .

Since the construction of the summands, as given by Bochner, is typified by the case $n=1$ we will verify the result for $n=1$ and indicate the general case. Let the base of T be $\{x \mid \sigma < x < \mathfrak{J}\}$. Then $T_1 = \{z \mid \operatorname{Re} z > \sigma\}$, $T_2 = \{z \mid \operatorname{Re} z < \mathfrak{J}\}$.

$$\begin{aligned} f(z) &= (z - \alpha)g(z) = \frac{(z - \alpha)}{2\Pi i} \int_c \frac{[f(w)/(w - \alpha)]}{w - z} dw \\ &= \frac{-1}{2\Pi i} \int_c \frac{f(w)}{w - \alpha} dw + \frac{1}{2\Pi i} \int_c \frac{f(w)}{w - z} dw \\ &= \frac{1}{2\Pi} \int_{-\infty}^{\infty} \frac{f(\mathfrak{J} + iv)}{\mathfrak{J} + iv - z} dv + \frac{1}{2\Pi} \int_{\infty}^{-\infty} \frac{f(\sigma + iv)}{\sigma + iv - z} idv \\ &= f_2(z) + f_1(z), \end{aligned}$$

since

$$\frac{1}{2\Pi i} \int_{\mathfrak{J}}^{\sigma} \frac{f(u + it)}{u + it - z} du \rightarrow 0 \quad \text{and} \quad \frac{1}{2\Pi i} \int_{\sigma}^{\mathfrak{J}} \frac{f(u - it)}{u - it - z} du \rightarrow 0$$

as $t \rightarrow \infty$ and $\sigma < \operatorname{Re} z < \mathfrak{J}$.

$$\begin{aligned} |f_2(z)| &= \frac{1}{2\Pi} \left| \int_{-\infty}^{\infty} \frac{f(\mathfrak{J} + iv)}{\mathfrak{J} + iv - z} dv \right| \\ &\leq \frac{1}{2\Pi} \int_{-\infty}^{\infty} \frac{M}{|\mathfrak{J} + iv - z| |\mathfrak{J} + iv - \alpha|^{\beta}} dv \\ &\leq \frac{1}{2\Pi} \int_{-\infty}^{\infty} \frac{M}{|v|^{1+\beta}} dv < \infty \end{aligned}$$

for $\operatorname{Re} z < \mathfrak{J}$, so that f_2 is bounded and similarly for f_1 . Furthermore, as $x \rightarrow \pm \infty$, f_1 and f_2 respectively tend to zero. The general case merely requires iterations.
