THEOREMS OF ACCOLA TYPE FOR HIGHER DIMENSIONAL MANIFOLDS

SU-SHING CHEN

Abstract. Two theorems of Accola concerning automorphisms of Riemann surfaces can be extended to higher dimensional manifolds. Formulas are obtained concerning signatures of compact oriented $4k$-dimensional differentiable manifolds and Euler-Poincaré characteristics of compact differentiable manifolds and compact complex manifolds.

1. Introduction. In [1], R. D. M. Accola has obtained formulas which relate invariants (such as the genera and the dimensions of spaces of meromorphic functions) of a Riemann surface $X$ and quotients of $X$ by certain subgroups of a finite automorphism group $G$ of $X$. The purpose of this note is to exhibit some generalizations to higher dimensional manifolds. The author would like to thank the referee and Professor Accola for their comments. Applications of our formulas and some related results will be given in a forthcoming note.

2. Differentiable actions of a finite group. We shall generalize the first theorem of Accola in [1] to differentiable actions of finite groups on compact differentiable manifolds. Instead of the Riemann-Hurwitz formula, we apply a formula of Conner [3] concerning differentiable actions of a finite group $G$ on a compact differentiable manifold $X$, namely, the Euler-Poincaré characteristic of $X/G$ is given by

$$
\chi(X/G) = \sum_{g \in G} \chi(F_g)/n,
$$

where $n$ is the order of $G$ and $F_g$ is the set of points in $X$ fixed under the element $g \in G$. It is clear that the first theorem in [1] is a consequence of the following.

Theorem 1. Let $X$ be a compact differentiable manifold admitting a finite group $G$ of diffeomorphisms. Let $G_1, G_2, \ldots, G_s$ be subgroups of $G$ so that $G = \bigcup_{i=1}^s G_i$. For indices $1 \leq i < j < \cdots < k \leq s$, let $G_{ij}\ldots k$...
480  SU-SHING CHEN

Let n, n_{ij}...k be the orders of G, G_{ij}...k. Then

\[ n_X(X/G) = \sum_{1 \leq i \leq s} n_{iX}(X/G_i) - \sum_{1 \leq i < j \leq s} n_{ijX}(X/G_{ij}) + \sum_{1 \leq i < j < k \leq s} n_{ijkX}(X/G_{ijk}) - \cdots \]

\[ - (-1)^s n_{12...sX}(X/G_{12...s}). \]

**Proof.** Formula (1) implies \( n_{i...k}X(X/G_{i...k}) = \sum_{\pi \in \chi_{ij...k}} \chi(\pi) \) for indices \( 1 \leq i < j < \cdots < k \leq s \). Now formula (2) follows from counting elements in G and the fact that

\[ 1 = \sum_i 1 - \sum_{i < j} 1 + \sum_{i < j < k} 1 \cdots. \]

**Corollary.** Suppose for \( 0 \neq i \neq j \neq 0 \), it happens that \( G_i \cap G_j = \{1\} \). G is then said to admit a partition. In that case, formula (2) becomes

\[ n_X(X/G) = \sum_{i=1}^s n_{iX}(X/G_i) + \chi(X) \left[ -\binom{s}{2} + \binom{s}{3} - \binom{s}{4} + \cdots \right] \]

or

\[ n_X(X/G) = \sum_{i=1}^s n_{iX}(X/G_i) + (1 - s)\chi(X). \]

3. **Finite groups of Accola type.** Let G be a finite group and \( G_1, G_2, \cdots, G_s \) be normal subgroups of G. We shall call G an Accola group if for each irreducible complex representation \( \pi \) of G there is an \( i \) (\( 1 \leq i \leq s \)) so that \( G_i \subseteq \text{kernel} \pi \). For indices \( 1 \leq i < j < \cdots < k \leq s \), let \( G_{ij}...k = G_i G_j \cdots G_k \). For a finite group G, we denote by \( \mathfrak{R}(G) \) the set of complex irreducible representations of G. Let A be a finite dimensional complex vector space such that A is the representation space of a complex representation \( \rho \) of G. The Maschke theorem implies that \( \rho \) is completely reducible and

\[ A = \sum_{\pi \in \mathfrak{R}(G)} \sum_{j=1}^{t_\pi} (A_\pi)_j, \]

where G acts irreducibly on \( (A_\pi)_j \) for each \( j \) and gives the irreducible representation \( \pi \) (\( \pi \) occurs in \( \rho \) \( t_\pi \) times). If \( q_\pi = t_\pi (\dim(A_\pi)_j) \), then

\[ \dim A = \sum_{\pi \in \mathfrak{R}(G)} q_\pi. \]

If \( N \) is a normal subgroup of G, let \( \hat{N} = \{ \pi \in \mathfrak{R}(G) | T \in N \Rightarrow \pi(T) = 1 \} \). That is \( \hat{N} \) is the set of irreducible representations which include \( N \) in
their kernels. The following two lemmas are included in [1].

**Lemma 1.** Let $A_N$ be the subspace of $A$ which $N$ leaves pointwise fixed, then $\dim A_N = \sum_{q \in q} q_e$.

**Lemma 2.** Let $G$ be an Accola group and $A$ be the representation space of a complex representation $\rho$ of $G$. Then

$$\dim A = \sum_{1 \leq i < j \leq s} \dim A_{ij} - \sum_{1 \leq i < j < k \leq s} (-1)^s \dim A_{ijk}$$

where, for indices $1 \leq i < j < \cdots < k \leq s$, $A_{ij \cdots k} = A_{g_{ij \cdots k}}$ the invariant subspace of $A$ under $G_{ij \cdots k}$.

4. **The signature formula.** Let $X$ be a compact oriented differentiable manifold of dimension $4k$. The signature of $X$ is defined as the signature of the quadratic form in $H^{2k}(X, \mathbb{R})$ given by the cup product. Thus $\text{Sign}(X) = p - q$, where $p$ is the number of $+$ signs in a diagonalization of the quadratic form and $q$ is the number of $-$ signs (see [4], [5]). If $G$ is a finite group of orientation preserving diffeomorphisms acting on $X$, then $H^{2k}(X, \mathbb{R})$ is a $G$-module. An Accola group $G$ of orientation preserving diffeomorphisms is called admissible if $(1 \leq i < j < \cdots < k \leq s) X/G_{ij \cdots k}$ and $X/G$ are again oriented manifolds. The action of $G$ on $H^{2k}(X, \mathbb{R})$ preserves $Q$. We may decompose $H^{2k}(X, \mathbb{R})$ as $H^{2k}(X, \mathbb{R}) = H^+ \oplus H^-$, where $H^+$ and $H^-$ are $Q$-orthogonal and where $Q$ is positive definite on $H^+$ and negative definite on $H^-$ and $T(H^+) = H^+$, $T(H^-) = H^-$ for $T \in G$. Thus, $\text{Sign}(X) = \dim H^+ - \dim H^-.

**Theorem 2.** Let $G$ be an admissible Accola group of orientation preserving diffeomorphisms of a compact oriented differentiable manifold $X$ of dimension $4k$. Then

$$\text{Sign}(X) = \sum_{1 \leq i < j \leq s} \text{Sign}(X/G_{ij}) - \sum_{1 \leq i < j < k \leq s} (-1)^s \text{Sign}(X/G_{ijk})$$

Proof. Lemma 2 implies that for $G$-invariant vector spaces $H^+$ and $H^-,$

$$\dim H^+ = \sum_{1 \leq i < j \leq s} \dim H^+_{ij} - \sum_{1 \leq i < j < k \leq s} (-1)^s \dim H^+_{ijk}$$

$$\dim H^- = \sum_{1 \leq i < j \leq s} \dim H^-_{ij} - \sum_{1 \leq i < j < k \leq s} (-1)^s \dim H^-_{ijk}$$

$$\text{Sign}(X) = \sum_{1 \leq i < j \leq s} \text{Sign}(X/G_{ij}) - \sum_{1 \leq i < j < k \leq s} (-1)^s \text{Sign}(X/G_{ijk}).$$
Subtracting (5) from (4), we get (3).

The above theorem is not exactly a generalization of Accola's second theorem, because the signature of a Riemann surface (any manifold of dimension \( \neq 4k \)) is defined to be zero.

5. **The Euler-Poincaré characteristic formula.** Let \( X \) be a compact complex manifold. We denote by \( H^{p,q}(X) \) the finite dimensional vector space of complex harmonic forms of type \((p, q)\) on \( X \) and denote by \( h^{p,q}(X) \) the dimension of \( H^{p,q}(X) \). The Euler-Poincaré characteristic \( \chi(X) \) of \( X \) is, according to [4],

\[
\chi(X) = \sum_{p+q} (-1)^{p+q} h^{p,q}(X).
\]

Suppose that \( X \) admits a finite group \( G \) of analytic automorphisms. In general \( X/G \) is not necessarily a manifold (see [2], [6]). We call an Accola group \( G \) of analytic automorphisms admissible if \( X/G_{ij} \cdots k \)
\((1 \leq i < j < \cdots < k \leq s)\) and \( X/G \) are manifolds. The vector space \( H^{p,q}(X) \) is invariant under \( G \) and hence is a representation space of \( G \) canonically.

**Theorem 3.** Let \( G \) be an admissible Accola group of analytic automorphisms of a compact complex manifold \( X \). Then

\[
h^{p,q}(X) = \sum_{1 \leq i \leq s} h^{p,q}(X/G_i) - \sum_{1 \leq i < j \leq s} h^{p,q}(X/G_{ij}) + \cdots - (-1)^s h^{p,q}(X/G_{12\cdots s}).
\]

**Proof.** This follows from Lemma 2.

**Theorem 4.** Let \( G \) be an admissible Accola group of analytic automorphisms of a compact complex manifold \( X \). Then

\[
\chi(X) = \sum_{1 \leq i \leq s} \chi(X/G_i) - \sum_{1 \leq i < j \leq s} \chi(X/G_{ij}) + \cdots - (-1)^s \chi(X/G_{12\cdots s}).
\]

**Proof.** This follows from

\[
\chi(X/G_{ij}\cdots k) = \sum_{p+q} (-1)^{p+q} h^{p,q}(X/G_{ij}\cdots k)
\]

for indices \( 1 \leq i < j < \cdots < k \leq s \).

Theorem 4 is a generalization of the second theorem of Accola. It would be interesting to see whether this theorem is still true for non-admissible groups.
