AN EXTREMAL PROBLEM FOR THE GEOMETRIC MEAN OF POLYNOMIALS

E. BELLER AND D. J. NEWMAN

Abstract. Let $M_{0,n}$ be the maximum of the geometric mean of all nth degree polynomials $\sum_{k=0}^{n} a_k e^{ikt}$ which satisfy $|a_k| = 1$, $k = 0, 1, \cdots, n$. We show the existence of certain polynomials $R_n$ whose geometric mean is asymptotic to $\sqrt{n}$, thus proving that $M_{0,n}$ is itself asymptotic to $\sqrt{n}$.

Consider the class $\mathcal{P}_n$ of all nth degree polynomials $\sum_{k=0}^{n} a_k z^k$ for which $|a_k| = 1$, $k = 0, 1, \cdots, n$. Following the usual notation, let

$$M_r(f) = \left((2\pi)^{-1} \int_{-\pi}^{\pi} |f(e^{i\theta})|^r d\theta\right)^{1/r}$$

for $r > 0$, and let

$$M_0(f) = G(f) = \exp\left((2\pi)^{-1} \int_{-\pi}^{\pi} \log |f(e^{i\theta})| d\theta\right),$$

so that, in particular, for $r = 0, 1, 2$, $M_r(f)$ is the geometric mean, arithmetic mean, and mean square of $f$, respectively.

Now, for $f \in \mathcal{P}_n$, and $0 \leq r < 2$, we have $M_r(f) \leq M_2(f) = (n + 1)^{1/2}$. The question arises, how close can $M_r(f)$ be to $(n + 1)^{1/2}$, the mean square? To formulate our question in more precise terms, let

$$M_{r,n} = \max_{f \in \mathcal{P}_n} M_r(f)$$

for $r < 2$, so that $M_{r,n} \leq (n + 1)^{1/2}$. For each $r < 2$, we now ask: Is $M_{r,n}$ asymptotic to $\sqrt{n}$ as $n \to \infty$?

Newman [3] constructed $P_n \in \mathcal{P}_n$ for which $M_2(P_n) = n^2 + O(n^{3/2})$, and thereby proved that $M_1(P_n) > \sqrt{n - c}$. Beller [1] noted that this...
implies the following, more complete result: $M_{r,n} > \sqrt{n-c/r}$, for $0 < r < 2$ ($c$ an absolute constant), thus answering our question affirmatively for all $r < 2$ except $r=0$.

It is the purpose of this paper to show that $M_{0,n} \sim \sqrt{n}$. It may be noted that this result yields an interesting corollary concerning the zeros of polynomials. Since, for all $f \in \mathcal{P}_n$, the product of all the zeros of $f(z)$ is numerically equal to 1, it follows from Jensen’s theorem that $G(f) = \prod |r_i|$, where the $r_i$ are the zeros of $f(z)$ for which $|r_i| > 1$. Thus, our result can be rephrased as follows: The maximum—taken over all $f \in \mathcal{P}_n$—of the product of the moduli of the zeros of $f(z)$ outside the unit circle, is asymptotic to $\sqrt{n}$.

Before proceeding with our theorem, let us review the situation for $r > 2$. Since, for such $r$, $M_r(f) \geq (n+1)^{1/r}$, we consider

$$m_{r,n} = \min_{f \in \mathcal{P}_n} M_r(f).$$

We also define $M_\infty(f) = \sup_{|\theta|} |f(e^{i\theta})|$. Beller [1] has shown that $m_{r,n}$ is asymptotic to $\sqrt{n}$, for $2 < r < \infty$. This, taken together with our present result, gives us an affirmative answer to our question for all $r \geq 0$, except $r = \infty$, which still remains unsettled.

We now state our

**Theorem.** $M_{0,n} \sim \sqrt{n}$. In fact, $M_{0,n} > \sqrt{n-c \log n}$, where $c$ is an absolute constant.

**Proof.** Choose $P_n \in \mathcal{P}_n$ which satisfy

$$M_\infty(P_n) = \sqrt{n} + O(1),$$

e.g., the $P_n$ which Newman [3] constructed. Now, in estimating $G(P_n)$, one encounters difficulty where $|P_n|$ is close to zero. We will show that, by appropriately changing the constant term of $P_n$, this difficulty is eliminated.

Let $f^+(x) = f(x)$ ($f(x) \geq 0$); $f^+(x) = 0$ ($f(x) < 0$). We will need the following well-known inequality:

$$\frac{1}{2\pi} \int_{-\pi}^{\pi} \log |e^{it} + z| \, dt = \log^+ |z|,$$

where $z$ is any complex number.

Now, let $Q_n(z) = P_n(z) - a_0$, where $a_0$ is the constant term of $P_n(z)$. By reversing the order of integration and applying (2), we find that

$$\frac{1}{2\pi} \int_{-\pi}^{\pi} \left( \frac{1}{2\pi} \int_{-\pi}^{\pi} \log |e^{it} + Q_n(e^{i\theta})| \, d\theta \right) \, dt = \frac{1}{2\pi} \int_{-\pi}^{\pi} \log^+ |Q_n(e^{i\theta})| \, d\theta.$$
Thus, by the First Mean Value Theorem, there exists a real $\delta$ such that

$$
(3) \quad (2\pi)^{-1} \int_{-\pi}^{\pi} \log |e^{i\theta} + Q_n(e^{i\theta})| \, d\theta = (2\pi)^{-1} \int_{-\pi}^{\pi} \log^+ |Q_n(e^{i\theta})| \, d\theta.
$$

Let $R_n(z) = e^{i\theta} + Q_n(z)$, so that $R_n \in \mathcal{P}_n$. Our Theorem now follows directly from the following

**Proposition.** $G(R_n) > \sqrt{n - c \log n}$, where $c$ is an absolute constant.

**Proof of Proposition.** By Minkowski's inequality we have $M_4(P_n) - 1 \leq M_4(Q_n) \leq M_4(P_n) + 1$, and this, combined with (1), yields

$$
(4) \quad (2\pi)^{-1} \int_{-\pi}^{\pi} |Q_n|^4 \, d\theta = n^2 + O(n^{3/2}).
$$

We also have

$$
(5) \quad (2\pi)^{-1} \int_{-\pi}^{\pi} |Q_n|^2 \, d\theta = n.
$$

We now need the following lemma, which is actually a reverse arithmetic-geometric inequality:

**Lemma 1.** If $f(x) \geq 0$, $\int_a^b f(x) \, dx = \lambda > 0$, and $\int_a^b f^2(x) \, dx = \mu$, then

$$
\int_a^b \log(1 + f(x)) \, dx \geq (\lambda^2/\mu) \log(1 + \mu/\lambda).
$$

**Proof.** Set $p(x) = (1/\lambda^2)f(x)$, so that $p(x)$ is a nonnegative weight function. Let $\mu/\lambda = m$, so that $\int_a^b f(x)p(x) \, dx = m$. In these terms, we want to show that

$$
\int_a^b \frac{\log(1 + f(x))}{f(x)} p(x) \, dx \geq (1/m) \log(1 + m).
$$

But direct differentiation shows that $\phi(t) = (1/t)\log(1 + t)$ is convex on $[0, \infty)$, so that we may apply Jensen's inequality (see Zygmund [4, Vol. I, p. 24]), namely,

$$
\int_a^b \phi(f(x))p(x) \, dx \geq \phi \left( \int_a^b f(x)p(x) \, dx \right). \quad \text{Q.E.D.}
$$

**Remark.** Since the function $(\lambda^2/\mu)\log(1 + \mu/\lambda)$ is increasing in $\lambda$, for $\lambda > 0$, and decreasing in $\mu$, the conclusion of Lemma 1 still holds under the weaker hypothesis $f(x) \geq 0$, $\int f(x) \, dx \geq \lambda > 0$, $\int f^2(x) \, dx \leq \mu$. 

Lemma 2. If $\int_0^1 F(x) \, dx \geq A > 1$ and $\int_0^1 F^2(x) \, dx \leq B$, then

$$\int_0^1 \log^+ F(x) \, dx \geq \frac{(A - 1)^2}{B - 2A + 1} \log \left( \frac{B - A}{A - 1} \right).$$

Proof. We apply our previous remark to $f(x) = (F(x) - 1)^+$, so that

$$\int_0^1 f(x) \, dx \geq \int_0^1 (F(x) - 1) \, dx \geq A - 1 > 0$$

and

$$\int_0^1 f^2(x) \, dx \leq \int_0^1 (F(x) - 1)^2 \, dx \leq B - 2A + 1,$$

and we conclude that

$$\int_0^1 \log^+ F(x) \, dx = \int_0^1 \log(1 + f(x)) \, dx \geq \frac{(A - 1)^2}{B - 2A + 1} \log \left( \frac{B - A}{A - 1} \right),$$

as required.

Now let $F(x) = |Q_n(e^{2\pi i x})|^2$. In terms of $F$, (4) and (5) become

$$\int_0^1 F(x) \, dx = n; \quad \int_0^1 F^2(x) \, dx \leq n^2 + c_1 n^{3/2},$$

where $c_1$ is some absolute constant. Applying Lemma 2, we have

$$(2\pi)^{-1} \int_{-\pi}^{\pi} \log^+ |Q_n(e^{i\theta})| \, d\theta = \frac{1}{2} \int_0^1 \log^+ F(x) \, dx$$

$$> \frac{1}{2} \left( \frac{1 - 2/n}{1 + c_1/\sqrt{n}} \right) \log n > \frac{1}{2} \log n - \left( \frac{c}{\sqrt{n}} \right) \log n,$$

where $c$ is another constant.

Combining (3) and (6), we conclude that

$$G(R_n) = \exp \left( (2\pi)^{-1} \int_{-\pi}^{\pi} \log^+ |Q_n(e^{i\theta})| \, d\theta \right)$$

$$\geq \sqrt{n} \exp(-c/\sqrt{n}) \log n > \sqrt{n} - c \log n,$$

thus proving the Proposition.
