GENERALIZATIONS OF A THEOREM OF MUTYLIN

SETH WARNER

Abstract. We generalize Mutylin's theorem that the only complete, locally bounded, additively generated topological fields are $\mathbb{R}$ and $\mathbb{C}$ by showing: (1) the only complete, locally bounded, additively generated topological division rings with left bounded commutator subgroup are $\mathbb{R}$, $\mathbb{C}$, and $\mathbb{H}$; (2) a commutative, Hausdorff topological ring $A$ with identity is a Banach algebra over $\mathbb{R}$, equipped with the absolute value $|.|^p$ for some $p \in (0, 1]$, if (and only if) $A$ is complete, locally bounded, additively generated, and possesses an invertible topological nilpotent.

In 1968, Mutylin [8, Theorem 1] proved that the only complete, additively generated, locally bounded fields were $\mathbb{R}$ and $\mathbb{C}$ (a topological ring is additively generated if it contains no proper open additive subgroups; any connected ring is additively generated). This theorem implies, of course, the commutative part of Pontrjagin's classification of locally compact, connected division rings. Mutylin's proof depended essentially on the Jordan Curve Theorem for the plane.

Here we shall generalize Mutylin's theorem in two ways, and our proofs will not depend on any deep properties of $\mathbb{C}$ other than the fact that $\mathbb{C}$ is locally compact and has roots of unity of all orders, a fact needed in elementary proofs of the Gelfand-Mazur theorem and Ostrowski's theorem.

Convexity is unneeded in proofs of basic theorems concerning general Banach algebras. More precisely, basic theorems, such as the Gelfand-Mazur theorem, hold for Banach algebras over $\mathbb{R}$ or $\mathbb{C}$ equipped with the absolute value $|.|^p$ for some $p \in (0, 1]$, as Želazko has shown [12].

A seminorm on a ring $K$ is a function $N$ from $K$ to $\mathbb{R}$ such that for all $x, y \in K$, $N(x) > 0$, $N(-x) = N(x)$, $N(xy) < N(x)N(y)$, and $N(x + y) < N(x) + N(y)$. The null space $N^{-1}(0)$ of a seminorm $N$ is an ideal, and $N$ is a norm if its null space is $(0)$. An absolute semivalue on a ring $K$ with identity is a seminorm $A$ such that $A(1) = 1$ and $A(xy) = A(x)A(y)$ for all $x, y \in K$. The null space of an absolute semivalue $A$ is a prime ideal, and $A$ is an absolute value if its null space is $(0)$.

If $N$ is a seminorm on $K$, we define $N_j$ by $N_j(x) = \lim_{n \to \infty} N(x^n)^{1/n}$. Then $x$ is a topological nilpotent (that is, $\lim_{n \to \infty} x^n = 0$) if and only if $N_j(x) < 1$. If $K$ is commutative, or if $K$ is a division ring whose commutator subgroup $\Gamma$ is norm-bounded, then $N_j$ is a seminorm. Indeed, in the latter case, to show that $N_j(x + y) < N_j(x) + N_j(y)$, one needs to modify the usual proof in the commutative case by...
using the variant of the Binomial Theorem that states that 

\[(x + y)^n = \sum_{k=0}^{n} \binom{n}{k} x^{n-k} y^k\]

where each \(s_{n,k}\) is the sum of \(\binom{n}{k}\) members of \(\Gamma\) and \(s_{n,0} = s_{n,n} = 1\); and to prove that \(N_s(xy) < N_s(x)N_s(y)\), one uses the fact that 

\[(xy)^n = g_n x^y^n\]

where \(g_n \in \Gamma\). A seminorm \(N\) is spectral if \(N = N_s\), or equivalently, if \(N(x^n) = N(x)^n\) for all \(x \in K\) and all \(n > 1\). If \(N_s\) is a seminorm, it is a spectral seminorm.

**Theorem 1.** Let \(K\) be a division ring equipped with a Hausdorff ring topology. The following conditions are sufficient (and necessary) for \(K\) to be topologically isomorphic to \(\mathbb{R}\), \(\mathbb{C}\), or the topological division ring \(\mathbb{H}\) of quaternions:

1. \(K\) is complete.
2. \(K\) is locally bounded.
3. \(K\) is additively generated.
4. The commutator subgroup \(\Gamma\) of \(K\) is left bounded.

**Proof.** \(K\) contains a nonzero topological nilpotent \([4, Exercise 21, p. 121]\), and there is a bounded neighborhood \(U\) of zero such that \(UU \subseteq U\) \([4, Exercise 20d), p. 121]\). Let \(V = \Gamma U\). Then \(V\) is a left bounded neighborhood of zero such that \(aV = Va\) for all \(a \in K\). By a generalization of a theorem of Cohn \([6, Theorem 6.1]\) due to Lipkina \([7]\), the topology of \(K\) is given by a norm \(N\), and as the topology of \(K\) is not discrete, \(\Gamma\) is norm bounded. Therefore \(N_s\) is a spectral norm (as \(K\) is a division ring). By a theorem of Aurora \([3, Theorem 1]\), \(N_s = \sup_{c \in K^*} A_c\), where for each \(c \in K^*\), \(A_c\) is an absolute value (as \(K\) is a division ring) satisfying \(A_c < N_s\) and \(A_c(c) = N_s(c)\). For each \(c \in K^*, \{x \in K: A_c(x) < 1\}\) is a neighborhood of zero and therefore is not an additive subgroup, so \(A_c\) is archimedean. Consequently, by Ostrowski's theorem \([5, Theorem 2, p. 131]\), there exist an isomorphism \(\sigma_c\) from \(K\) onto a division subring of \(\mathbb{H}\) and a number \(p_c \in (0, 1]\) such that \(A_c(x) = |\sigma_c(x)|^{p_c}\) for all \(x \in K\). Therefore \(K\) has characteristic zero and thus contains the rational field \(\mathbb{Q}\). Let \(r \in \mathbb{Q}^*\). Since \(|r|^{p_c} = A_c(r) = N_s(r)\), \(|r| < 1\) if and only if \(N_s(r) < 1\), that is, if and only if \(r\) is a topological nilpotent. Consequently, the topology induced on \(\mathbb{Q}\) is not discrete and also is not the \(p\)-adic topology for any prime \(p\) (since the topological nilpotents for the \(p\)-adic topology form a nonzero additive subgroup of \(\mathbb{Q}\)). Therefore by 1 and \([10, Corollary 2]\), the closure of \(\mathbb{Q}\) in \(K\) is the real field \(\mathbb{R}\).

Since \(K\) is locally bounded as a ring, it is a fortiori locally bounded as a vector space over its subfield \(\mathbb{R}\). Consequently, by a theorem of Aoki \([1]\), rediscovered by Rolewicz \([9]\), there is a vector space norm \(M\) on the \(\mathbb{R}\)-vector space \(K\) relative to the absolute value \(|.\|\) on \(\mathbb{R}\) for some \(p \in (0, 1]\) that defines the topology of \(K\). As multiplication is jointly continuous in both variables, there is an equivalent Banach algebra norm \(||.||\) (defined by \(||x|| = t^{-2}M(x)\), where \(t > 0\) is such that \(M(x) < t\) and \(M(y) < t\) imply \(M(xy) < 1\)). Thus \(K\) is a normed division algebra over \(\mathbb{R}\), equipped with \(|.\|^{p}\). By the Gelfand-Mazur theorem, \(K\) is topologically isomorphic to \(\mathbb{R}\), \(\mathbb{C}\), or \(\mathbb{H}\).

A similar proof characterizes those commutative topological rings with identity that are real Banach algebras:
Theorem 2. Let $A$ be a Hausdorff commutative topological ring with identity $e$. The following conditions are sufficient (and necessary) for $A$ to be a Banach algebra over $\mathbb{R}$, equipped with the absolute value $\| \cdot \|^p$ for some $p \in (0, 1]$:

1. $A$ is complete.
2. $A$ is locally bounded.
3. $A$ is additively generated.
4. $A$ contains an invertible topological nilpotent.

Proof. The conditions are necessary, for $r \cdot e$ is an invertible topological nilpotent for any nonzero $r \in \mathbb{R}$ such that $|r| < 1$, and $A$ is connected and hence additively generated.

Sufficiency. By 2, 4, and a generalization of Cohn's theorem [2, Corollary of Theorem 3], [11, Theorem 4], the topology of $A$ is given by a norm $N$. Let $J$ be the null space of the associated spectral seminorm $N_c$. By Aurora's theorem [3, Theorem 1], $N_c = \sup_{x \in A \setminus J} A_c$, where for each $c \in A \setminus J$, $A_c$ is an absolute semivalue satisfying $A_c \leq N_c$ and $A_c(c) = N_c(c)$. Let $J_c$ be the null space of $A_c$, a prime ideal of $A$, and let $K_c$ be the quotient field of $A/J_c$. In a natural way $A_c$ induces an absolute value on $A/J_c$, which has a unique extension to an absolute value $A'_c$ on $K_c$. If the closed unit ball $B_c$ of $A'_c$ were an additive subgroup, then $B_c \cap (A/J_c)$ would also be an additive subgroup; its inverse image under the canonical epimorphism $q_c$ from $A$ to $A/J_c$, namely, $\{ x \in A : A_c(x) < 1 \}$, would then be an additive subgroup, which is impossible by 3, for as $A_c \leq N_c \leq N$, that set is a neighborhood of zero. Therefore $A'_c$ is an archimedean absolute value, so $A/J_c$ has characteristic zero and hence $A$ does also.

Next, we shall show that for each integer $m > 1$, $m \cdot e$ is invertible. In the contrary case, there would be a proper ideal and hence a maximal ideal $M$ containing $m \cdot e$. As $A$ is a complete normed ring, the set of its invertible elements is open, so $M$ would be a closed ideal. Then $A/M$ would clearly satisfy conditions 1–4 and hence, by what we have just proved, would have characteristic zero, a contradiction, since $m \cdot e \in M$.

Therefore $A$ contains the rational field $\mathbb{Q}$. By Ostrowski's theorem, there exist an isomorphism $\sigma_c$ from $K_c$ onto a subfield of $\mathbb{C}$ and a number $p_c \in (0, 1]$ such that $A'_c(z) = |\sigma_c(z)|^{p_c}$ for all $z \in K_c$. Let $u_c = \sigma_c \circ q_c$, a nonzero homomorphism from $A$ to $\mathbb{C}$; then $A_c(x) = |u_c(x)|^{p_c}$ for all $x \in A$, and in particular, $A_c(r) = |r|^{p_c}$ for all $r \in \mathbb{Q}$. Proceeding as in the proof of Theorem 1, we conclude that $A$ contains $\mathbb{R}$ and that $A$ is a Banach algebra over $\mathbb{R}$ relative to the absolute value $\| \cdot \|^p$ for some $p \in (0, 1]$.

Corollary. A commutative Hausdorff topological ring $A$ with identity $e$ is a Banach algebra over $\mathbb{C}$, equipped with the absolute value $\| \cdot \|^p$ for some $p \in (0, 1]$, if and only if $A$ satisfies 1–4 of Theorem 2 and, in addition, possesses an element $i$ such that $i^2 = -e$.
