AN APPLICATION OF YAU'S MAXIMUM PRINCIPLE TO CONFORMALLY FLAT SPACES

S. I. GOLDBERG

ABSTRACT. Results of M. Tani on compact conformally flat manifolds and of M. Okumura on compact hypersurfaces of Euclidean space are extended to complete spaces by an application of S.-T. Yau's "maximum principle".

1. Introduction. M. Tani [3] proved that a compact and orientable Riemannian manifold admitting a conformally flat metric of positive Ricci curvature and constant scalar curvature is a space form, that is, it is a constant curvature space. It is our purpose to extend this result to complete Riemannian manifolds with Ricci curvature bounded from below. This will be accomplished by employing a "maximum principle" due to S.-T. Yau. In fact, the following statement is obtained.

THEOREM 1. *Let M be a d-dimensional, $d > 3$, complete, conformally flat Riemannian manifold whose Ricci curvature is bounded from below. If its scalar curvature r is a positive constant and* $\operatorname{tr} Q^2 < r^2/(d-1)$, *then M is a space form.*

2. Definitions and notation. Let (M, g) be a Riemannian manifold with metric g. The curvature transformation $R(X, Y)$, $X, Y \in M_m$, where M_m is the tangent space at $m \in M$, and g are related by

$$R(X, Y) = \nabla_{[X,Y]} - [\nabla_X, \nabla_Y],$$

where ∇ is the Riemannian connection. In terms of a basis $X_1, \ldots, X_d$ of M_m, we set

$$R_{ijkh} = g(R(X_i, X_j)X_k, X_h), \qquad R_{ij} = \operatorname{tr}(X_k \to R(X_i, X_k)X_j),$$
$$t_{i_1 \ldots i_p} = t(X_{i_1}, \ldots, X_{i_p}), \qquad \nabla_i t_{i_1 \ldots i_p} = (\nabla_{X_i} t)(X_{i_1}, \ldots, X_{i_p}).$$

We denote the scalar curvature by r, that is, $r = \operatorname{tr} Q$, where $Q = (R^i_j)$ and $R^i_j = g^{ik}R_{jk}$. The manifold (M, g) is *conformally flat* if g is conformally related to a locally flat metric.

3. The Laplacian of $\operatorname{tr} Q^2$. The following formula may be found in [1]:

$$\frac{1}{2}\Delta \operatorname{tr} Q^2 = g^{ab}\nabla_a R^{ij}\nabla_b R_{ij} + R^{ij}g^{ab}\nabla_a(\nabla_b R_{ij} - \nabla_i R_{bj}) + \frac{1}{2}R^{ij}\nabla_j\nabla_i r + K, \tag{3.1}$$

where $\operatorname{tr} Q^2$ is the square length of the Ricci tensor, and

$$K = R^{ik}(R^j_i R_{jk} + R^{hj}R_{ijhk}).$$

Key words and phrases. Conformally flat, Ricci curvature, scalar curvature.

If r is a constant, the third term on the r. h. s. of (3.1) vanishes. If, moreover, M is conformally flat and $d > 3$, the second term on the right also vanishes (see [1]) and (3.1) reduces to

$$\tfrac{1}{2}\Delta \operatorname{tr} Q^2 = K + g(\nabla Q, \nabla Q).$$

4. Proof of Theorem 1. Since M is conformally flat it can be shown that

$$(d-1)(d-2)K = d(d-1)\operatorname{tr} Q^3 - r(2d-1)\operatorname{tr} Q^2 + r^3.$$

Put $S = Q - (r/d)I$, $I =$ identity. Then, from $\operatorname{tr} S^2 > 0$, we see that $\operatorname{tr} Q^2 > r^2/d$ with equality holding if and only if, M is an Einstein space. Since r is a constant, the Laplacian Δf^2 of the function $f^2 = \operatorname{tr} S^2, f > 0$, satisfies $\Delta f^2 = \Delta \operatorname{tr} Q^2$. Thus,

$$\tfrac{1}{2}\Delta f^2 = K + g(\nabla Q, \nabla Q). \tag{4.1}$$

Moreover,

$$(d-1)(d-2)K = d(d-1)\left(\operatorname{tr} S^3 + \frac{3r}{d}f^2 + \frac{r^3}{d^2}\right) - r(2d-1)\left(f^2 + \frac{r^2}{d}\right) + r^3. \tag{4.2}$$

The following lemma may be found in [2].

LEMMA 1. *Let a_i, $i = 1, \ldots, d$, be real numbers with*

$$\sum_{i=1}^{d} a_i = 0, \quad \sum_{i=1}^{d} a_i^2 = k^2, \qquad k = \text{const} > 0.$$

Then,

$$-\frac{d-2}{\sqrt{d(d-1)}}k^3 < \sum_{i=1}^{d} a_i^3 < \frac{d-2}{\sqrt{d(d-1)}}k^3.$$

Applying Lemma 1 to the eigenvalues of S, (4.2) yields the inequality

$$(d-1)K > f^2\left(r - \sqrt{d(d-1)}\, f\right).$$

We conclude from (4.1) that

$$\frac{d-1}{2}\Delta f^2 > f^2\left(r - \sqrt{d(d-1)}\, f\right). \tag{4.3}$$

LEMMA 2 (S.-T. YAU [4]). *Let M be a complete Riemannian manifold with Ricci curvature bounded below. Let u be a C^2 function with* $\sup u < \infty$. *Then, there exists a sequence $\{p_\nu\}$ in M such that*

$$\lim_{\nu\to\infty} \|du(p_\nu)\| = 0, \qquad \lim_{\nu\to\infty} (\Delta u)(p_\nu) < 0, \qquad \lim_{\nu\to\infty} u(p_\nu) = \sup u.$$

Applying Lemma 2, the inequality (4.3) gives rise to the inequality

$$\lim_{\nu\to\infty} f^2(p_\nu)\left\{r - \sqrt{d(d-1)}\, f(p_\nu)\right\} < 0.$$

Hence, either $f^2 \equiv 0$ or $\sup f > r/\sqrt{d(d-1)}$, the latter implying $\sup \operatorname{tr} Q^2 > r^2/(d-1)$. The former says that $\operatorname{tr} Q^2 = r^2/d$, so g is an Einstein metric. However, since g is conformally flat, it is a constant curvature metric.

The condition tr $Q^2 < r^2/(d-1)$ is essential. For, if $M = M_1 \times N$, where M_1 has constant curvature and N is 1-dimensional, then M is conformally flat, its Ricci curvature is bounded below, r is constant and tr $Q^2 = r^2/(d-1)$.

In a similar manner, we obtain the following extension of a theorem of Okumura [2].

THEOREM 2. *Let M be a d-dimensional complete connected hypersurface of R^{d+1} with Ricci curvature bounded from below. If its mean curvature* tr H *is constant and* tr $H^2 < (\mathrm{tr}\, H)^2/(d-1)$, *then M is a totally umbilical hypersurface.*

The inequality in Theorem 2 is the best possible as one sees by considering $M = S^{d-1} \times R$.
