HOMOLOGICAL INDEPENDENCE OF INJECTIVE HULLS
OF SIMPLE MODULES
OVER CERTAIN NONCOMMUTATIVE RINGS

JONATHAN S. GOLAN

Abstract. We study noncommutative rings $R$ having the property that there is no
nonzero homomorphism between injective hulls of nonisomorphic simple left
$R$-modules. For rings satisfying the condition that the torsion theory cogenerated
by the injective hull of a simple left $R$-module is always jansian, we characterize
this property in terms of the lattice of torsion theories on the category of left
$R$-modules.

0. Background and notation. Throughout the following $R$ will denote an associativ-
etive (but not necessarily commutative) ring with unit element $1$ and $R$-mod will
denote the category of unitary left $R$-modules and module homomorphisms.
Morphisms in $R$-mod will be written as acting on the right. If $M$ is an object of
$R$-mod then the injective hull of $M$ will be denoted by $E(M)$. We will select, once
and for all, a complete set of representatives of isomorphism classes of simple
objects of $R$-mod and will denote this set by $R$-simp.

The complete brouwerian lattice of all (hereditary) torsion theories on $R$-mod
will be denoted by $R$-tors. Notation and terminology concerning $R$-tors will follow
[3]. In particular, if $M$ is an object of $R$-mod then $\xi(M)$ will denote the smallest
torsion theory in $R$-tors relative to which $M$ is torsion and $\chi(M)$ will denote the
largest torsion theory in $R$-tors relative to which $M$ is torsionfree. (Note that this is
precisely the torsion theory cogenerated by $E(M)$. ) The unique minimal element of
$R$-tors is then $\xi = \xi(0)$ and the unique maximal element of $R$-tors is $\chi = \chi(0)$. The
lattice operations on $R$-tors are defined as follows: if $U \subseteq R$-tors then a left
$R$-module is a $U$-torsion if and only if it is torsion with respect to every member
of $U$; the module is $\bigvee U$-torsionfree if and only if it is torsionfree with respect to
every member of $U$. If $M$ is an object of $R$-mod and if $\tau \in R$-tors then the unique
largest $\tau$-torsion submodule of $M$ will be denoted by $T_{\tau}(M)$. Note that $M / T_{\tau}(M)$ is
then $\tau$-torsionfree.

The class of all objects of $R$-mod torsion with respect to a given element $\tau$ of
$R$-tors is closed under taking submodules, homomorphic images, extensions, and
arbitrary direct sums. It is not in general closed under taking injective hulls; when
this condition holds, the torsion theory is said to be stable. It is also not in general

closed under taking arbitrary direct products; when this condition holds, the torsion theory is said to be \textit{jansian}. Stable and jansian torsion theories are both amply studied in [3].

1. \textit{H}-rings. Following [6], we say that a ring \( R \) is a \textit{left H-ring} if and only if \( \text{Hom}_R(E(M_1), E(M_2)) = 0 \) for any pair of distinct elements \( M_1 \) and \( M_2 \) of \( R\)-simp. Commutative \( H \)-rings have recently been studied by Camillo [1], who showed that rings regular in the sense of von Neumann, polynomial rings in finitely-many indeterminates over a field, and the ring of continuous functions on the unit interval are all of this type. Polynomial rings in infinitely-many indeterminates over a field are not \( H \)-rings. If \( M_1 \) and \( M_2 \) are distinct elements of \( R \)-simp (where \( R \) is no longer assumed to be commutative) then \( \text{Hom}_R(M_1, E(M_2)) = 0 \) and so a sufficient condition for \( R \) to be a left \( H \)-ring is that the torsion theory \( \chi(M) \) be stable for every \( M \in R\)-simp. Examples of noncommutative rings having this property can be found, for instance, in [5]. Moreover, left \( QI \)-rings (i.e., those rings over which every quasi-injective left \( R \)-module is injective) and left \( V \)-rings (those rings over which every simple left \( R \)-module is injective) are clearly left \( H \)-rings. These rings and their applications are discussed in [2].

(1.1). \textbf{Proposition.} \textit{Any factor ring of a left H-ring is a left H-ring.}

\textbf{Proof.} Let \( R \) be a left \( H \)-ring and let \( S = R/I \) be a factor ring of \( R \). Then \( S \)-simp = \{ \( M \in R \)-simp \mid IM = 0 \} is a complete set of representatives of the isomorphism classes of simple left \( S \)-modules [6]. Moreover, if \( N_1 \) and \( N_2 \) are two left \( S \)-modules then \( \text{Hom}_S(N_1, N_2) = \text{Hom}_R(N_1, N_2) \); if \( N \) is a left \( S \)-module then the injective hull of \( N \) in \( S \)-mod is \( E(N) = \{ x \in E(R) \mid lx = 0 \} \) [6, Proposition 2.27].

Now let \( M_1 \) and \( M_2 \) be distinct elements of \( S \)-simp and, for \( i = 1, 2 \), let \( E'(M_i) \) be the injective hull of \( M_i \) in \( S \)-mod. Then each \( E'(M_i) \) is an \( S \)-submodule of \( E(M_i) \) and so, if there exists a nonzero \( S \)-homomorphism from \( E'(M_1) \) to \( E'(M_2) \) then it can be extended to a nonzero \( R \)-homomorphism from \( E(M_1) \) to \( E(M_2) \), which is impossible since \( R \) is a left \( H \)-ring. Thus \( S \) too must be a left \( H \)-ring. \( \square \)

(1.2). \textbf{Proposition.} \textit{If \( R \) is a ring satisfying the condition that } \( T_{x(M_i)}(R) + T_{x(M_j)}(R) = R \) \textit{for any pair \( M_1, M_2 \) of distinct elements of } \( R \)-simp \textit{then } \( R \) \textit{is a left } \( H \)-\textit{ring. The converse holds if } \( R \) \textit{satisfies the additional condition that } \( \chi(M) \) \textit{is jansian for every } \( M \in R \)-simp.

\textbf{Proof.} Let \( M_1 \) and \( M_2 \) be distinct elements of \( R \)-simp and assume that \( 0 \neq \alpha \in \text{Hom}_R(E(M_1), E(M_2)) \). Since \( R = T_{x(M_1)}(R) + T_{x(M_2)}(R) \), we can write \( 1 = a + b \), where \( a \in T_{x(M_1)}(R) \) and \( b \in T_{x(M_2)}(R) \). But \( \text{Hom}_R(T_{x(M_i)}(R), E(M_i)) = 0 \) for \( i = 1, 2 \) and so, in particular, \( T_{x(M_i)}(R) = \{ 0 : E(M_i) \} \) for \( i = 1, 2 \). Thus for any \( x \in E(M_i) \) we have \( xa = (1x)\alpha = (ax + bx)\alpha = (bx)\alpha = b(x\alpha) = 0 \), which contradicts the choice of \( \alpha \). Therefore \( R \) is a left \( H \)-ring.

Now, conversely, assume that \( R \) is a left \( H \)-ring satisfying the condition that \( \chi(M) \) is jansian for every \( M \in R \)-simp. Let \( M_1 \) and \( M_2 \) be distinct elements of \( R \)-simp and set \( I = T_{x(M_1)}(R) + T_{x(M_2)}(R) \). Assume that this is a proper ideal of \( R \). Then \( I \) is contained in a maximal left ideal \( H \) of \( R \). Moreover, for \( i = 1, 2 \) we see
that \( R/T_{x(M_j)}(R) \) is \( \chi(M_i) \)-torsionfree and so there exists an index set \( \Omega(i) \) and an \( R \)-monomorphism from \( R/T_{x(M_j)}(R) \) into \( E(M_i)^{\Omega(i)} \). If \( \nu_i: R/T_{x(M_j)}(R) \to R/H \) is the canonical surjection then, by injectivity, there exists an \( R \)-homomorphism \( \alpha_i \) making the diagram

\[
\begin{array}{ccc}
R/T_{x(M_j)}(R) & \xrightarrow{\nu_i} & E(M_i)^{\Omega(i)} \\
\downarrow & & \downarrow \alpha_i \\
R/H & \longrightarrow & E(R/H)
\end{array}
\]

commute. In particular, this implies that \( E(M_i)^{\Omega(i)} \) is not \( \chi(R/H) \)-torsion. Since \( \chi(R/H) \) is jansian, this implies that \( E(M_i) \) is not \( \chi(R/H) \)-torsion for \( i = 1, 2 \) and so \( \text{Hom}_R(E(M_i), E(R/H)) \neq 0 \) for \( i = 1, 2 \). This contradicts the hypothesis that \( R \) is a left \( H \)-ring. \( \square \)

Since the lattice \( R \)-tors is complete brouwerian, every \( \tau \in R \)-tors has a meet pseudocomplement which, following the notation of [3], we will denote by \( \tau^\perp \). Then \( \tau \land \tau^\perp = \xi \) and \( \tau^\perp > \tau' \) for every torsion theory \( \tau' \in R \)-tors satisfying the condition \( \tau \land \tau' = \xi \). Tébyrcé [7] has given a complete characterization of \( \tau^\perp \) as follows: if we denote the set of all \( \tau \)-torsion elements of \( R \)-simp by \( \tau \)-simp then \( \tau^\perp = \land \{ \chi(M)|M \in \tau \text{-simp} \} \).

(1.3). Proposition. A ring \( R \) is a left \( H \)-ring if and only if \( \xi(E(M))^\perp = \xi(M)^\perp \) for every \( M \in R \)-simp.

**Proof.** If \( M_1 \) and \( M_2 \) are distinct elements of \( R \)-simp and if \( 0 \neq \alpha \in \text{Hom}_R(E(M_1), E(M_2)) \) then \( E(M_1) \alpha \) is a nonzero submodule of \( E(M_2) \) and so, by simplicity, \( M_2 \subseteq E(M_1) \alpha \). This implies that \( M_2 \in \xi(E(M_1))-\text{torsion} \). On the other hand, if \( M_2 \) is \( \xi(E(M_1))-\text{torsion} \) then there exists a nonzero \( R \)-homomorphism from \( E(M_1) \) to \( E(M_2) \). Thus we see that the condition that \( R \) be a left \( H \)-ring is equivalent to the condition that \( \xi(E(M)) \)-simp = \( \{ M \} \) for any simple left \( R \)-module \( M \) or, in other words, that \( \xi(E(M))^\perp = \chi(M) \) for all such \( M \). But, by Tébyrcé’s characterization, it is immediate that \( \chi(M) = \xi(M)^\perp \) for any simple left \( R \)-module \( M \), and so we are done. \( \square \)

Recall that a lattice \( L \), every element \( u \) of which has a meet pseudocomplement \( u^\perp \), is said to be a Stone lattice if and only if \( (u_1 \land u_2)^\perp = u_1^\perp \lor u_2^\perp \) for all \( u_1, u_2 \in L \). Stone lattices are an important class of distributive lattices and have been fully characterized. See [4] for details.

(1.4). Proposition. If \( R \) is a left \( H \)-ring satisfying the condition that \( \chi(M) \) is jansian for every \( M \in R \)-simp then \( R \)-tors is a Stone lattice.

**Proof.** If \( \tau \) and \( \sigma \) are two elements of \( R \)-tors then \( \tau \land \sigma < \tau \) and so \( (\tau \land \sigma)^\perp > \tau^\perp \). Similarly \( (\tau \land \sigma)^\perp > \sigma^\perp \) and so \( (\tau \land \sigma)^\perp > \tau^\perp \lor \sigma^\perp \). Assume that this inequality is strict. Then there exists a nonzero left \( R \)-module \( N \) which is \( (\tau \land \sigma)^\perp \)-torsion and \( (\tau^\perp \lor \sigma^\perp) \)-torsionfree. That is to say,

1. \( \text{Hom}_R(N, E(M)) = 0 \) for all \( M \in \tau \text{-simp} \cap \sigma \text{-simp} \);
2. there exists an index set \( \Omega \) and an \( R \)-monomorphism \( \phi: N \to \prod \{ E(M) | M \in \tau \text{-simp} \} \).
(3) there exists an index set $\Lambda$ and an $R$-monomorphism

$$\psi: \mathcal{N} \to \left( \prod \{ E(M) | M \in \sigma\text{-simp} \} \right)^\Lambda.$$ 

In particular, from (1) we see that $N\psi$ is contained in

$$E_1 = \left( \prod \{ E(M) | M \in \tau\text{-simp} \setminus \sigma\text{-simp} \} \right)^\Omega$$

and $N\psi$ is contained in

$$E_2 = \left( \prod \{ E(M) | M \in \sigma\text{-simp} \setminus \tau\text{-simp} \} \right)^\Lambda.$$ 

Since $E_2$ is injective, there exists an $R$-homomorphism $\beta: E_1 \to E_2$ satisfying $\phi\beta = \psi$. Since $\chi(M)$ is jansian for every $M \in \sigma\text{-simp} \setminus \tau$-simp by assumption, it follows that $\chi(E_2) = \wedge \{ \chi(M) | M \in \sigma\text{-simp} \setminus \tau\text{-simp} \}$ is also jansian. In particular, this implies that there must exist simple left $R$-modules $M_1 \in \tau\text{-simp} \setminus \sigma\text{-simp}$ and $M_2 \in \sigma\text{-simp} \setminus \tau$-simp for which we have $\text{Hom}_R(E(M_1), E(M_2)) \neq 0$, contradicting the hypothesis that $R$ is a left $H$-ring. This implies that we must indeed have $(\tau \wedge \sigma)^\perp = \tau^\perp \vee \sigma^\perp$. □

(1.5). Proposition. For a ring $R$ satisfying the condition that $\chi(M)$ is jansian for every simple left $R$-module $M$ the following conditions are equivalent:

(1) $R$ is a left $H$-ring.

(2) (i) $\tau$-tors is a Stone lattice; and

(ii) if $M_1$ and $M_2$ are distinct elements of $\sigma$-simp then

$$T_{\chi(M_1)}(R) + T_{\chi(M_2)}(R) = T_{\chi(M_1) \vee \chi(M_2)}(R).$$

Proof. By Proposition 1.4 we already know that (1) implies (2)(i). Moreover, if $M_1$ and $M_2$ are distinct elements of $\sigma$-simp then by Proposition 1.2 we have $R = T_{\chi(M_1)}(R) + T_{\chi(M_2)}(R) \subseteq T_{\chi(M_1) \vee \chi(M_2)}(R) \subseteq R$ and so we must have (2)(ii). Conversely, assume (2). If $M_1$ and $M_2$ are distinct elements of $\sigma$-simp then by [3, Proposition 12.1] we have $\xi = \xi(M_1) \wedge \xi(M_2)$ and so, by (2)(i), we have $\chi = \xi^\perp = \xi(M_1)^\perp \vee \xi(M_2)^\perp = \chi(M_1) \vee \chi(M_2)$. This implies that $R = T_{\chi(M_1) \vee \chi(M_2)}(R)$ and so by (2)(ii) we have $R = T_{\chi(M_1)}(R) + T_{\chi(M_2)}(R)$. By Proposition 1.2, this implies that $R$ is a left $H$-ring. □

2. The jansian condition. The “converse” portion of Proposition 1.2 is not true unless some other condition is present besides the condition that $R$ is a left $H$-ring. To see this, we note that the ring $\mathbb{Z}$ of integers is a left $H$-ring since the simple left $\mathbb{Z}$-modules are just those of the form $\mathbb{Z}/(p)$, where $p$ is a prime integer. For each such $p$, $E(\mathbb{Z}/(p)) = \mathbb{Z}(p^\infty)$; see [6] for details. On the other hand, since $\mathbb{Z}$ is an integral domain, we have $T_\chi(\mathbb{Z}) = 0$ for all $\chi \neq \tau \in \mathbb{Z}$-tors. (This example was supplied to me by Jay Shapiro in a private communication.)

The condition imposed in §1—namely that $\chi(M)$ is jansian for every simple left $R$-module $M$—is sufficient though probably not necessary. It is not the purpose of this note to enter in detail into the ramifications of this condition, but it is worth pointing out two extreme examples.

(1) A ring $R$ is said to be left semiartinian if and only if every nonzero left $R$-module has a nonzero socle. If $R$ is a left semiartinian ring then any torsion
theory $\chi \neq \tau \in R$-tors is of the form $\bigwedge \{\chi(M) | M \in A\}$ for some nonempty subset $A$ of $R$-simp. As a result, if $R$ is a left semiartinian ring then every torsion theory of the form $\chi(M)$ for some simple left $R$-module $M$ is jansian if and only if every element of $R$-tors is jansian. By [3, Proposition 22.22] we see that this happens if and only if the ring $R$ is right perfect. A ring $R$ is left stable if and only if every element of $R$-tors is stable. By Proposition 1.3, it is clear that left stable rings are left $H$-rings. Left stable left semiartinian rings are completely characterized in [3, Proposition 23.8] and such rings need not be right perfect. Hence we see that the jansian condition is not a consequence of the condition that $R$ be a left $H$-ring.

(2) A ring $R$ is said to be left local if and only if all simple left $R$-modules are isomorphic. If $M$ is a simple left $R$-module and if $R$ is left local then for any proper left ideal $I$ of $R$ we have a canonical epimorphism from $R/I$ to $M$ and so, in particular, $\text{Hom}_R(R/I, E(M)) \neq 0$. Thus there are no proper $\chi(M)$-dense left ideals of $R$ and so $\chi(M) = \xi$. This torsion theory is always jansian and so the jansian condition holds for any left local ring.

Acknowledgment. Portions of this note were written while the author was spending a sabbatical leave at Indiana University in Bloomington. The author wishes to thank the Department of Mathematics at Indiana University for its generous hospitality and support during his visit.
