

## PARAPRODUCTS AND COMMUTATORS OF MARTINGALE TRANSFORMS

RODRIGO BAÑUELOS AND ANDREW G. BENNETT

(Communicated by Daniel S. Stroock)

**ABSTRACT.** We define paraproducts in a probabilistic setting and study their boundedness properties. As an application of paraproduct techniques, we prove a generalization of the commutator result of Coifman-Rochberg-Weiss [6].

**1. Introduction.** Let  $M_k$  be a martingale with respect to the  $\sigma$ -fields  $\mathcal{F}_k$  and let  $d_k = M_k - M_{k-1}$ . We call  $d_k$  the difference sequence of the martingale  $M_k$ . Let  $e_k$  be a sequence of random variables with  $e_k$  measurable with respect to  $\mathcal{F}_{k-1}$ , that is,  $e_k$  is predictable, and  $e_0 = 0$ . Assume  $|e_k| \leq 1$  for all  $k$ . Let  $V_k = \sum_{j=0}^k e_j d_j$ . Then  $V_k$  is called the martingale transform of  $M_k$  by  $e_k$ . These operators were introduced by D. L. Burkholder in [2]. They have become a powerful tool in the interplay between probabilistic harmonic analysis and harmonic analysis in Euclidean spaces. Most recently they have received a great deal of attention because of their connections to the geometry of Banach spaces and vector valued singular integrals [4]. The purpose of this paper is to study a particular type of martingale transform, whose definition is motivated by the paraproducts of Bony [1].

Let  $B_t$  be an  $n$ -dimensional Brownian motion on a probability space  $(\Omega, \mathcal{F}, P)$ ,  $\mathcal{F}_t = \sigma(B_s : 0 \leq s \leq t)$  and for any  $X \in L^2(\Omega)$  we will use  $t \mapsto X_t$  to denote the almost surely continuous version of  $t \mapsto E[X|\mathcal{F}_t]$ . To simplify the notation, we will just write  $L^p$  instead of  $L^p(\Omega)$  where there is no danger of confusion.

**DEFINITION 1.1.** If  $X, Y \in L^2$ , we define the *paraproduct* of  $X$  and  $Y$  by

$$(1.1) \quad \mathcal{P}(X, Y) = \int_0^\infty X_t dY_t$$

and the *remainder* term of  $X$  and  $Y$  by

$$(1.2) \quad \mathcal{R}(X, Y) = \int_0^\infty d\langle X, Y \rangle_t = \langle X, Y \rangle$$

where  $\langle X, Y \rangle_t$  is the covariance process of  $X$  and  $Y$ .

Notice that  $\mathcal{P}(X, Y) \neq \mathcal{P}(Y, X)$  in general but we always have  $\mathcal{R}(X, Y) = \mathcal{R}(Y, X)$ . Also, it follows from the Itô formula that

$$(1.3) \quad X_t Y_t = \mathcal{P}(X, Y)_t + \mathcal{P}(Y, X)_t + \mathcal{R}(X, Y)_t.$$

While paraproducts are originally defined for  $X, Y \in L^2$ , we will of course extend them to operators on  $L^p$  by continuity whenever possible. So we are led to consider the questions of boundedness of paraproducts. If  $X \in L^\infty$ , then it follows from the Burkholder-Gundy inequalities that  $\mathcal{P}(X, \cdot) : L^p \rightarrow L^p$  for  $1 < p < \infty$ . The boundedness properties of paraproducts, however, are much richer than this. First, we recall a few definitions. The space  $H^p$ ,  $0 < p < \infty$ , consists of those functions  $X$  such that the maximal function  $\sup_t |X_t| = X^*$  belongs to  $L^p$ . Doob's inequality implies that  $H^p = L^p$  for  $1 < p < \infty$ . The quadratic variation  $\langle X \rangle_t$  is the continuous increasing process which makes  $X_t^2 - \langle X \rangle_t$  a martingale. We simply write  $\langle X \rangle$  for  $\langle X \rangle_\infty$ . The Burkholder-Gundy inequalities say that  $\|X^*\|_p \approx \|\langle X \rangle^{1/2}\|_p$  for  $0 < p < \infty$  (see [7, p. 154]). For  $1 < p < \infty$ ,  $\|X^*\|_p \approx \|X\|_p$  where  $X \in L^p$  such that  $X_t = E[X|\mathcal{F}_t]$ . The space BMO consists of those functions  $X$  in  $L^2$  such that for all stopping times  $\tau$ ,

$$E[|X - X_\tau|^2 | \mathcal{F}_\tau] \leq c \text{ a.e.}$$

for some constant  $c$ . The square root of the smallest constant for which this holds is the BMO norm of  $X$ . Often we shall use the equivalent formulations

$$E \left[ \int_\tau^\infty d\langle X \rangle_s | \mathcal{F}_\tau \right] \leq c \text{ a.e.} \quad \text{and} \quad E[(X - X_\tau)^2] \leq cP[\tau < \infty].$$

The following results are in analogy with those for analytic paraproducts proved by Coifman and Meyer [5]. Notice, however, that in our case we seem to be able to prove more. Chao and Long have independently obtained similar results for discrete martingales (personal communication).

- THEOREM 1.1.** (i)  $\mathcal{P}(\cdot, \cdot) : (H^p, \text{BMO}) \rightarrow H^p$ ,  $0 < p < \infty$ ,  
 (ii)  $\mathcal{P}(\cdot, \cdot) : (L^\infty, \text{BMO}) \rightarrow \text{BMO}$ ,  
 (iii)  $\mathcal{R}(\cdot, \cdot) : (H^p, \text{BMO}) \rightarrow L^p$ ,  $1 \leq p \leq \infty$ ,  
 (iv)  $\mathcal{P}(\cdot, \cdot) : (H^p, H^q) \rightarrow H^r$ ,  $0 < p, q < \infty$ ,  $1/r = 1/p + 1/q$ ,  
 (v)  $\mathcal{R}(\cdot, \cdot) : (H^p, H^q) \rightarrow L^r$ ,  $0 < p, q < \infty$ ,  $1/r = 1/p + 1/q$ .

$H^1 \neq L^1$ , and we have the following result.

- THEOREM 1.2.** (i)  $\mathcal{P}(\cdot, \cdot) : (L^1, \text{BMO}) \rightarrow WL^1$ ,  
 (ii)  $\mathcal{R}(\cdot, \cdot) : (L^1, \text{BMO}) \rightarrow WL^1$ . Here  $WL^1$  means weak  $L^1$ .

For any  $X \in L^2$ , there is an essentially unique  $\mathcal{F}_t$ -adapted  $\mathbf{R}^n$ -valued map  $s \mapsto H_s$  such that  $E[\int_0^\infty |H_s|^2 ds] < \infty$  and  $X_t = E[X] + \int_0^t H_s \cdot dB_s$  (a.s.  $P$ ). We now have the following.

**DEFINITION 1.2.** Let  $A : [0, \infty) \rightarrow \mathbf{R}^n \otimes \mathbf{R}^n$  be adapted to  $\mathcal{F}_t$  and bounded. The martingale transform of  $X \in L^2$  by  $A$  is

$$(A * X) \equiv \int_0^\infty A_s H_s \cdot dB_s.$$

It should be noted that  $(A * X)_t = \int_0^t A_s H_s \cdot dB_s$ .

**THEOREM 1.3.** Let  $X \in L^p$ ,  $Y \in \text{BMO}$  and  $A : [0, \infty) \rightarrow \mathbf{R}^n \otimes \mathbf{R}^n$  be adapted to  $\mathcal{F}_t$  and bounded. We define the commutator  $C_Y^A(X) = Y(A * X) - A * (XY)$ . Then  $C_Y^A \in L^p$  for  $1 < p < \infty$  and

$$\|C_Y^A(X)\|_p \leq C_p \|A\|_\infty \|Y\|_{\text{BMO}} \|X\|_p.$$

Theorems 1.1 and 1.2 are proved in §2. Here we also discuss some other properties of  $\mathcal{P}(X, Y)$  and  $\mathcal{R}(X, Y)$ . Theorem 1.3 is proved in §3. From this we deduce the basic result of R. Coifman, R. Rochberg and G. Weiss [6] that the commutator of the conjugate operator in the circle and multiplication by a BMO function is bounded in  $L^p$ ,  $1 < p < \infty$ . A similar result follows for Riesz transforms in  $\mathbf{R}^n$  and multiplier operators of Laplace transform type. That is, our result holds for all those operators that can be obtained as conditional expectations of martingale transforms.

**2. Boundedness of paraproducts and remainders.** In this section, we prove Theorems 1.1 and 1.2, as well as some other results. We start by computing the adjoints of our operators.

**THEOREM 2.1.** *Let  $X, Y, Z \in L^\infty$ . Then*

- (i)  $E[\mathcal{P}(X, Y)Z] = E[Y\mathcal{P}(X, Z)],$
- (ii)  $E[\mathcal{P}(X, Y)Z] = E[X\mathcal{R}(Y, Z)].$

**PROOF.**

$$\begin{aligned} E[\mathcal{P}(X, Y)Z] &= E\left[\left(\int_0^\infty X_t dY_t\right) Z\right] = E\left[\int_0^\infty X_t d\langle Y, Z \rangle_t\right] \\ &= E\left[Y\left(\int_0^\infty X_t dZ_t\right)\right] = E[Y\mathcal{P}(X, Z)]. \end{aligned}$$

This proves (i). To prove (ii), we start the same way but now we write  $\langle Y, Z \rangle_t$  as the difference of a pair of nondecreasing processes of finite variation,  $\langle Y, Z \rangle_t = A_t - B_t$ .  $A_t$  and  $B_t$  are the processes of positive and negative variation respectively. By stopping, we can assume  $A_t$  and  $B_t$  are bounded. Then (see [7, p. 191])

$$E\left[\int_0^\infty X_t dA_t\right] = E\left[\int_0^\infty E[X|\mathcal{F}_t] dA_t\right] = E\left[\int_0^\infty X dA_t\right] = E[XA_\infty].$$

So

$$\begin{aligned} E[\mathcal{P}(X, Y)Z] &= E\left[\int_0^\infty X_t d\langle Y, Z \rangle_t\right] = E\left[\int_0^\infty X_t dA_t\right] - E\left[\int_0^\infty X_t dB_t\right] \\ &= E[XA_\infty] - E[XB_\infty] = E[X(A_\infty - B_\infty)] \\ &= E[X\langle Y, Z \rangle] = E[X\mathcal{R}(Y, Z)] \end{aligned}$$

which proves (ii).

**PROOF OF THEOREM 1.1.** We start by proving part (iii). First, we recall the following lemma.

**LEMMA 2.1 (GARSIA [9]).** *Let  $A_t$  be a positive continuous increasing process with  $A_0 = 0$ . If there is a positive random variable  $Y$  such that  $E[A_\infty - A_t|\mathcal{F}_t] \leq E[Y|\mathcal{F}_t]$  for any time  $t$ , then, for  $1 \leq p < \infty$ ,  $E[(A_\infty)^p] \leq p^p E[Y^p]$ .*

We may assume, by stopping, that  $X$  is bounded. Write the process of finite variation  $\langle X, Y \rangle_t = A_t - B_t$  where  $A_t$  and  $B_t$  are nonnegative nondecreasing processes.  $A_t$  and  $B_t$  are the positive and negative variations of  $\langle X, Y \rangle_t$  respectively. Then

$$\begin{aligned} E[\langle (A_\infty + B_\infty) - (A_t + B_t) \rangle|\mathcal{F}_t] &= E\left[\int_t^\infty |d\langle X, Y \rangle_s|\Big|\mathcal{F}_t\right] \\ &\leq c\|Y\|_{\text{BMO}} E[\langle X \rangle^{1/2}|\mathcal{F}_t] \end{aligned}$$

where we have applied the local version of Fefferman’s inequality [7, p. 190]. Since this holds for any time  $t$ , we may apply Lemma 2.1 to conclude that

$$E[(A + B)^p] \leq c_p \|Y\|_{\text{BMO}}^p E[(X)^{p/2}] \leq c_p c_\tau \|Y\|_{\text{BMO}}^p E[|X|^p]$$

since  $1 \leq p < \infty$ . This completes the proof of part (iii).

We are now ready to prove part (i). For  $1 < p < \infty$ , (i) follows from (ii) in Theorem 2.1 together with (iii) in Theorem 1.1.

For the case  $0 < p \leq 1$  of (i), we shall use the atomic decomposition. A function  $A \in H^p$  is an atom if there is a stopping time  $\tau$  such that

$$(2.1) \quad A_t \equiv 0 \quad \text{for } t \leq \tau$$

and

$$(2.2) \quad (A^*)^p \leq P[\tau < \infty]^{-1}.$$

LEMMA 2.2. For all  $X \in H^p$ ,  $0 < p \leq 1$ , there exists a sequence of atoms  $A^n$ ,  $n \in \mathbf{Z}$  and a sequence of numbers  $b_n$ ,  $n \in \mathbf{Z}$ , such that

$$(2.3) \quad X_t = \sum_{n=-\infty}^{\infty} b_n A_t^n$$

and

$$(2.4) \quad c_p E[(X^*)^p] \leq \sum_{n=-\infty}^{\infty} |b_n|^p \leq C_p E[(X^*)^p].$$

The proof of this lemma may be found in [7, p. 216].

LEMMA 2.3. If  $Y \in \text{BMO}$  then for any stopping time  $\tau$  and any  $0 < p \leq 1$

$$(2.5) \quad E[(\langle Y \rangle_\infty - \langle Y \rangle_\tau)^{p/2}] \leq \|Y\|_{\text{BMO}}^p P[\tau < \infty].$$

PROOF. By Hölder’s inequality, for  $0 < p \leq 2$ ,

$$E[(\langle Y \rangle_\infty - \langle Y \rangle_\tau)^{p/2}] \leq E[(\langle Y \rangle_\infty - \langle Y \rangle_\tau)^{p/2} P[\tau < \infty]^{1-p/2}] \leq \|Y\|_{\text{BMO}}^p P[\tau < \infty].$$

Now suppose  $A$  is an atom in  $H^p$ ,  $0 < p \leq 1$ . Then

$$\begin{aligned} \|\mathcal{P}(A, Y)\|_{H^p}^p &= E[(\mathcal{P}(A, Y))^{p/2}] = E\left[\left(\int_\tau^\infty A_s^2 d\langle Y \rangle_s\right)^{p/2}\right] \\ &\leq E\left[(A^*)^p \left(\int_\tau^\infty d\langle Y \rangle_s\right)^{p/2}\right] \\ &\leq P[\tau < \infty]^{-1} E[(\langle Y \rangle_\infty - \langle Y \rangle_\tau)^{p/2}] \leq C_p \|Y\|_{\text{BMO}}^p \end{aligned}$$

where the last inequality follows from Lemma 2.3. For general  $X \in H^p$  the result now follows from (2.3), (2.4) and the above. Part (i) of Theorem 1.1 is now proved for all  $0 < p < \infty$ .

It remains to prove parts (ii), (iv) and (v). We start with (ii). Let  $\tau$  be any stopping time

$$\begin{aligned} E[|\mathcal{P}(X, Y)_\infty - \mathcal{P}(X, Y)_\tau|^2 | \mathcal{F}_\tau] &= E\left[\int_\tau^\infty X_s^2 d\langle Y \rangle_s | \mathcal{F}_\tau\right] \\ &\leq \|X\|_\infty^2 E[\langle Y \rangle - \langle Y \rangle_\tau | \mathcal{F}_\tau] \\ &= \|X\|_\infty^2 E[|Y - Y_\tau|^2 | \mathcal{F}_\tau] \leq \|X\|_\infty^2 \|Y\|_{\text{BMO}}^2 \end{aligned}$$

which proves (ii).

The proof of (iv) is also very easy. Applying the Burkholder-Gundy we get

$$\begin{aligned} (E[\langle \mathcal{P}(X, Y) \rangle^{r/2}]^{1/r}) &= \left( E \left[ \left( \int_0^\infty X_s^2 d\langle Y \rangle_s \right)^{r/2} \right] \right)^{1/r} \\ &\leq (E[(X^*)^r \langle Y \rangle^{r/2}])^{1/r} \leq E[(X^*)^p]^{1/p} E[\langle Y \rangle^{q/2}]^{1/q} \\ &\approx \|X\|_{H^p} \|Y\|_{H^q} \end{aligned}$$

where the last inequality follows from Hölder’s inequality.

It remains to prove (v). Applying the Kunita-Watanabe inequality we get

$$E[|\langle X, Y \rangle|^\tau]^{1/\tau} \leq (E[\langle X \rangle^{\tau/2} \langle Y \rangle^{\tau/2}])^{1/\tau} \leq \|\langle X \rangle^{1/2}\|_p \|\langle Y \rangle^{1/2}\|_q \approx \|X\|_{H^p} \|Y\|_{H^q}$$

which proves (v). So Theorem 1.1 is completely proved.

PROOF OF THEOREM 1.2. We start with part (i). Let  $X \in L^1$  and  $Y \in \text{BMO}$  with  $\|Y\|_{\text{BMO}} \leq 1$ . We want to show that

$$(2.6) \quad P[|\mathcal{P}(X, Y)| > \lambda] \leq c\|X\|_1/\lambda.$$

We follow the argument in Burkholder [3] very closely. First, our proof above shows that for any stopping time  $\tau$  and  $1 < p < \infty$ ,

$$(2.7) \quad \|\mathcal{P}(X, Y)_\tau\|_p \leq c_p \|Y\|_{\text{BMO}} \|X_\tau\|_p.$$

Let  $\lambda > 0$  and set  $\tau_\lambda = \inf\{t : |X_t| > \lambda\}$ . Then, by (i) in Theorem 1.1

$$\begin{aligned} P[|\mathcal{P}(X, Y)| > \lambda, X^* \leq \lambda] &\leq P\left[\left|\int_0^{\tau_\lambda} X_s dY_s\right| > \lambda\right] \leq \frac{1}{\lambda^2} E\left[\left(\int_0^{\tau_\lambda} X_s dY_s\right)^2\right] \\ &= \frac{1}{\lambda^2} E[|\mathcal{P}(X, Y)_{\tau_\lambda}|^2] \leq \frac{c}{\lambda^2} \|Y\|_{\text{BMO}}^2 \|X_{\tau_\lambda}\|_2^2 \\ &\leq \frac{c}{\lambda} \|Y\|_{\text{BMO}}^2 \|X\|_1. \end{aligned}$$

Then, applying Doob’s weak type inequality we have

$$\begin{aligned} P[|\mathcal{P}(X, Y)| > \lambda] &\leq P[|\mathcal{P}(X, Y)| > \lambda, X^* \leq \lambda] + P[X^* > \lambda] \\ &\leq \frac{(1 + c\|Y\|_{\text{BMO}}^2)}{\lambda} \|X\|_1 \end{aligned}$$

which is (2.6) and part (i) of Theorem 1.2 is proven. Part (ii) is proved in the same way using the fact that  $\|\langle X, Y \rangle_\tau\|_2 \leq c\|Y\|_{\text{BMO}} \|X_\tau\|_2$ .

We shall now investigate some converses. Our first result is

THEOREM 2.2. *Suppose  $Y \in L^2$  and  $\mathcal{P}(\cdot, Y) : L^2 \rightarrow L^2$  with  $\|\mathcal{P}(X, Y)\|_2 \leq c_2\|X\|_2$ . Then  $Y \in \text{BMO}$  and  $\|Y\|_{\text{BMO}} \leq c_2$ .*

PROOF. Let  $\tau$  be any stopping time and let  $\tau' = \inf\{t > \tau : |Y_t - Y_\tau| > \varepsilon\}$  for some fixed  $\varepsilon > 0$ . Then  $X_t = Y_{t \wedge \tau'} - Y_{t \wedge \tau}$  is bounded and thus in  $L^2$ . Since  $\mathcal{P}(\cdot, Y)$  is bounded on  $L^2$  we have

$$(2.8) \quad E\left[\left(\int_0^\infty (Y_{t \wedge \tau'} - Y_{t \wedge \tau}) dY_t\right)^2\right] \leq c_2^2 E[(Y_{\tau'} - Y_\tau)^2].$$

But we can evaluate the right-hand side of (2.8) and see

$$\begin{aligned} E \left[ \left( \int_0^\infty (Y_{t \wedge \tau'} - Y_{t \wedge \tau}) dY_t \right)^2 \right] &= E \left[ \int_\tau^\infty (Y_{t \wedge \tau'} - Y_{t \wedge \tau})^2 d\langle Y \rangle_t \right] \\ &= E \left[ \int_{\tau'}^\infty \varepsilon^2 d\langle Y \rangle_t + \int_\tau^{\tau'} (Y_t - Y_\tau)^2 d\langle Y \rangle_t \right] \\ &\geq E \left[ \int_{\tau'}^\infty \varepsilon^2 d\langle Y \rangle_t \right]. \end{aligned}$$

So we have

$$(2.9) \quad E \left[ \left( \int_0^\infty (Y_{t \wedge \tau'} - Y_{t \wedge \tau}) dY_t \right)^2 \right] \geq \varepsilon^2 E[\langle Y \rangle_\infty - \langle Y \rangle_{\tau'}].$$

Then since  $|Y_{t \wedge \tau'} - Y_{t \wedge \tau}| \leq \varepsilon$ , we have

$$(2.10) \quad E[(Y_{\tau'} - Y_\tau)^2] \leq \varepsilon^2 P[\tau < \infty].$$

Combining (2.8), (2.9) and (2.10) we see

$$(2.11) \quad E[\langle Y \rangle_\infty - \langle Y \rangle_{\tau'}] \leq c_2^2 P[\tau < \infty].$$

Then

$$\begin{aligned} E[(Y_\infty - Y_\tau)^2] &= E[\langle Y \rangle_\infty - \langle Y \rangle_\tau] = E[\langle Y \rangle_\infty - \langle Y \rangle_{\tau'}] + E[\langle Y \rangle_{\tau'} - \langle Y \rangle_\tau] \\ &= E[\langle Y \rangle_\infty - \langle Y \rangle_{\tau'}] + E[(Y_{\tau'} - Y_\tau)^2] \leq (c_2^2 + \varepsilon^2) P[\tau < \infty]. \end{aligned}$$

So  $Y \in \text{BMO}$  and by letting  $\varepsilon \rightarrow 0$ , we see  $\|Y\|_{\text{BMO}} \leq c_2$ .

**THEOREM 2.3.** *Suppose  $Y \in L^2$  and  $\mathcal{R}(\cdot, Y): L^2 \rightarrow L^2$  with  $\|\mathcal{R}(X, Y)\|_2 \leq c_2 \|X\|_2$ . Then  $Y \in \text{BMO}$  and  $\|Y\|_{\text{BMO}} \leq c_2^2 + 1$ .*

**PROOF.** Let  $\tau$  be any stopping time and let  $X_t = Y_t - Y_{t \wedge \tau}$ . Then  $X_t$  is an  $L^2$  martingale and thus

$$\|\mathcal{R}(X, Y)\|_2 \leq c_2 \|X\|_2$$

or equivalently

$$E[(\langle Y \rangle - \langle Y \rangle_\tau)^2] \leq c_2^2 E[\langle Y \rangle - \langle Y \rangle_\tau]$$

which we can write as

$$(2.12) \quad 0 \leq E[c_2^2(\langle Y \rangle - \langle Y \rangle_\tau) - (\langle Y \rangle - \langle Y \rangle_\tau)^2].$$

If  $k$  is any positive constant, we may rewrite (2.12) as

$$(2.13) \quad \begin{aligned} &E[(\langle Y \rangle - \langle Y \rangle_\tau)^2 - c_2^2(\langle Y \rangle - \langle Y \rangle_\tau); \langle Y \rangle - \langle Y \rangle_\tau \geq k] \\ &\leq E[c_2^2(\langle Y \rangle - \langle Y \rangle_\tau) - (\langle Y \rangle - \langle Y \rangle_\tau)^2; \langle Y \rangle - \langle Y \rangle_\tau < k]. \end{aligned}$$

Now consider the function  $f(x) = x^2 - c_2^2 x - x$ . Choose  $k$  such that for all  $x \geq k$ ,  $f(x) > 0$ , or equivalently, for all  $x \geq k$ ,  $x^2 - c_2^2 x \geq x$ . Using this  $k$  in (2.13) we obtain

$$\begin{aligned} &E[\langle Y \rangle - \langle Y \rangle_\tau; \langle Y \rangle - \langle Y \rangle_\tau \geq k] \\ &\leq E[(\langle Y \rangle - \langle Y \rangle_\tau)^2 - c_2^2(\langle Y \rangle - \langle Y \rangle_\tau); \langle Y \rangle - \langle Y \rangle_\tau \geq k] \\ &\leq E[c_2^2(\langle Y \rangle - \langle Y \rangle_\tau) - (\langle Y \rangle - \langle Y \rangle_\tau)^2; \langle Y \rangle - \langle Y \rangle_\tau < k] \\ &\leq c_2^2 E[\langle Y \rangle - \langle Y \rangle_\tau; \langle Y \rangle - \langle Y \rangle_\tau < k]. \end{aligned}$$

So

$$\begin{aligned} E[\langle Y \rangle - \langle Y \rangle_\tau] &= E[\langle Y \rangle - \langle Y \rangle_\tau; \langle Y \rangle - \langle Y \rangle_\tau < k] \\ &\quad + E[\langle Y \rangle - \langle Y \rangle_\tau; \langle Y \rangle - \langle Y \rangle_\tau \geq k] \\ &\leq (1 + c_2^2)E[\langle Y \rangle - \langle Y \rangle_\tau; \langle Y \rangle - \langle Y \rangle_\tau < k] \\ &\leq k(1 + c_2^2)P[\tau < \infty], \end{aligned}$$

and  $Y \in \text{BMO}$  with  $\|Y\|_{\text{BMO}} \leq \sqrt{k(1 + c_2^2)}$ . Since the smallest  $k$  that satisfies the condition above is  $k = c_2^2 + 1$ , we obtain  $\|Y\|_{\text{BMO}} \leq c_2^2 + 1$ .

In both our converses, we have assumed that  $Y \in L^2$ . This is a weak condition compared to our conclusion that  $Y \in \text{BMO}$ . We could weaken our initial hypothesis on  $Y$  further if we strengthen our assumptions about the boundedness of the paraproduct and the remainder term. For instance, if we assume that  $\mathcal{R}(\cdot, Y)$  is bounded  $L^p \rightarrow L^p$  for  $1 < p < \infty$ , we can show that  $Y \in \bigcup_{p>1} L^p$  implies  $Y \in \text{BMO}$ . This can be easily seen from the fact that if  $Y \in L^p$  and  $\|\mathcal{R}(X, Y)\|_p \leq c\|X\|_p$  then

$$\|Y\|_{2p} = E[\langle Y \rangle^p] = E[|\mathcal{R}(Y, Y)|^p] \leq c\|Y\|_p$$

so  $Y$  is in  $L^{2p}$  and  $L^2 \subset L^{2p}$  since  $p > 1$ .

**3. Boundedness of commutators of martingale transforms and projections.** In this section we prove Theorem 1.3 and use it to prove the commutator result of Coifman, Rochberg and Weiss [6]. We have already done most of the work in §2. Let us remind the reader that if  $X \in L^p$ , then  $A * X \in L^p$  with  $\|A * X\|_p \leq c_p \|A\|_\infty \|X\|_p$  with  $1 < p < \infty$ .

PROOF OF THEOREM 1.3. Expanding by the Itô formula, we can write,

$$(3.1) \quad Y(A * X) = \mathcal{P}(Y, A * X) + \mathcal{P}(A * X, Y) + \mathcal{R}(Y, A * X)$$

and

$$(3.2) \quad XY = \mathcal{P}(X, Y) + \mathcal{P}(Y, X) + \mathcal{R}(X, Y).$$

Since the martingale transforms map  $L^p$  into  $L^p$  and  $Y \in \text{BMO}$ , the results proven in §2 show that  $\mathcal{P}(A * X, Y)$ ,  $\mathcal{R}(Y, A * X)$ ,  $A * \mathcal{P}(X, Y)$  and  $A * \mathcal{R}(X, Y)$  are all in  $L^p$  with norms bounded by  $c_p \|A\|_\infty \|Y\|_{\text{BMO}} \|X\|_p$ . To show that  $C_Y^A$  also has this property, all we have to do is show that the same holds for  $\mathcal{P}(Y, A * X) - A * \mathcal{P}(Y, X)$ . But a trivial calculation shows this term is actually zero and the theorem is proven.

Using the techniques of Varopoulos [11] to reduce matters to honest probability spaces, one can easily verify that all the results above hold for martingales on the infinite probability space of background radiation and obtain commutator results for those operators in  $\mathbf{R}^n$  that can be obtained as the conditional expectation (projection) of martingale transforms. For example, we can obtain results for the Riesz transforms [10] and multipliers of Laplace transform type [11]. To keep things at an elementary level, however, we only do this for the unit disk. Let  $D = \{z \in \mathbf{C}: |z| < 1\}$  and  $T = \partial D$ , the unit circle, equipped with the probability measure  $dm = d\theta/2\pi$ . Let  $f \in \text{BMO}(T)$  and denote by  $u_f$  its harmonic extension to  $D$ . It is well known that  $f \in \text{BMO}(T)$  if and only if (see [8, p. 238])

$$(3.3) \quad \|f\|_{\text{BMO}(T)} = \left( \sup_{z \in D} \int_T |f(e^{i\theta}) - u_f(z)|^2 P_z(\theta) dm(\theta) \right)^{1/2} < \infty$$

where  $P_z(\theta)$  is the Poisson kernel for  $D$ . We take (3.3) as our definition of  $BMO(T)$ . We refer the reader to [8] for many of the important properties of  $BMO(T)$ .

Let  $B_t$  be Brownian motion in  $D$  and let  $\tau_D$  be its first exit time. We may write (3.3) as

$$(3.4) \quad \|f\|_{BMO(T)} = \left( \sup_{z \in D} E_z [|f(B_{\tau_D}) - u_f(z)|^2] \right)^{1/2} < \infty$$

( $E_z$  denotes expectation with  $B_0 = z$ ). By the Itô formula and the strong Markov property, this is equivalent to

$$(3.5) \quad \|f\|_{BMO(T)} = \left\| \sup_{\eta < \tau_D} \left( E \left[ \int_{\eta}^{\tau_D} |\nabla u(B_s)|^2 ds \middle| \mathcal{F}_{\eta} \right] \right)^{1/2} \right\|_{\infty}$$

where  $\eta$  is a stopping time and  $E = E_0$ . Thus, the random variable  $Mf = f(B_{\tau_D})$  is in  $BMO$ . To avoid confusion we shall write  $BMO(\Omega)$  for the martingale  $BMO$  and  $L^p(\Omega)$  for the martingale  $L^p$ -spaces.

Now suppose  $g \in L^p(T)$  for  $1 < p < \infty$ . If  $v_g$  is the harmonic extension of  $g$  and  $A(z)$  is a  $2 \times 2$  matrix valued function in  $D$ , we define the operators

$$A * (Mg) = \int_0^{\tau_D} A(B_s) \nabla v_g(B_s) \cdot dB_s$$

and

$$T_A g(e^{i\theta}) = E^{\theta} \left[ \int_0^{\tau_D} A(B_s) \nabla v_g(B_s) \cdot dB_s \right]$$

where  $E^{\theta}$  is the expectation with respect to Brownian motion conditions to exit  $D$  at  $e^{i\theta}$ . We call  $T_A$  the projection of the martingale transform  $A * (Mg)$ .

**THEOREM 3.1.** *Set  $[T_A, f](g) = fT_Ag - T_A(fg)$ . Then for all  $1 < p < \infty$*

$$\|[T_A, f](g)\|_p \leq c_p \|A\| \|f\|_{BMO(T)} \|g\|_p$$

where

$$\|A\| = \sup_{z \in D} \left( \sup_{\substack{v \in \mathbf{R}^2 \\ |v|=1}} |A(z)v| \right) < \infty.$$

**PROOF.** The key to the proof is the following claim:

$$(3.6) \quad [T_A, f](g)(e^{i\theta}) = E^{\theta} [C_{Mf}^A(Mg)].$$

Once we establish (3.6), Theorem 1.3 and the fact that condition expectation contracts  $L^p$  norms (Jensen's inequality) gives

$$\begin{aligned} \|[T_A, f](g)\|_{L^p(T)} &\leq \|C_{Mf}^A(Mg)\|_{L^p(\Omega)} \leq c_p \|A\| \|Mf\|_{BMO(\Omega)} \|Mg\|_{L^p(\Omega)} \\ &= c_p \|A\| \|f\|_{BMO(T)} \|g\|_{L^p(T)}. \end{aligned}$$

To establish (3.6) we write

$$(3.7) \quad \begin{aligned} [T_A, f](g)(e^{i\theta}) &= f(\theta) E^{\theta} \left[ \int_0^{\tau_D} A(B_s) \nabla v_g(B_s) \cdot dB_s \right] \\ &\quad - E^{\theta} \left[ \int_0^{\tau_D} A(B_s) \nabla w_{fg}(B_s) \cdot dB_s \right] \end{aligned}$$

where  $w_{fg}$  is the harmonic extension of  $fg$  and

$$(3.8) \quad E^\theta [C_{Mf}^A(Mg)] = E^\theta [Mf(A * Mg) - A * (MfMg)].$$

Now

$$\begin{aligned} f(\theta)E^\theta \left[ \int_0^{\tau_D} A(B_s) \nabla v_g(B_s) \cdot dB_s \right] \\ = E^\theta \left[ f(B_{\tau_D}) \int_0^{\tau_D} A(B_s) \nabla v_g(B_s) \cdot dB_s \right] = E^\theta [Mf(A * Mg)]. \end{aligned}$$

So all we need prove is that

$$E^\theta \left[ \int_0^{\tau_D} A(B_s) \nabla w_{fg}(B_s) \cdot dB_s \right] = E^\theta [A * (MfMg)].$$

But this is trivial since  $MfMg = Mfg$ .

The case when  $A(z) = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}$  gives the conjugate operator and hence the Coifman-Rochberg-Weiss result [6] is contained in Theorem 3.1. Many other multipliers can be obtained by taking  $A(z)$  with  $\|A\| < \infty$  and which commute with rotations of the plane.

The authors would like to thank D. Stroock for many helpful comments about an earlier draft of this paper.
