

WELL-BOUNDED AND SCALAR-TYPE SPECTRAL OPERATORS ON SPACES NOT CONTAINING c_0

IAN DOUST

(Communicated by Paul S. Muhly)

ABSTRACT. It is known that a necessary and sufficient condition for a well-bounded operator on a weakly complete complex Banach space to be scalar-type spectral is that its decomposition of the identity be of bounded variation. We show in this paper that this condition is necessary and sufficient exactly when the Banach space does not contain a subspace isomorphic to c_0 .

A well-bounded operator on a Banach space X is one which admits a functional calculus for the absolutely continuous functions on some compact interval of the real line. It is often of interest to know whether a well-bounded operator is scalar-type spectral. Scalar-type spectral operators possess a larger functional calculus and give rise to unconditional, rather than conditional, spectral expansions. Whereas scalar-type spectral operators can be represented as an integral with respect to a spectral measure, a well-bounded operator on X possesses a representation in terms of a uniformly bounded increasing family of projections known as a decomposition of the identity for X . This representation is much less satisfactory than that for scalar-type spectral operators since if T is a well-bounded operator on X , the projections in an associated decomposition of the identity act not on X but on X^* . Furthermore, the decomposition of the identity is not in general uniquely determined by the well-bounded operator. If the operator $T \in B(X)$ possesses a functional calculus for the absolutely continuous functions on the compact interval $[a, b] \subset \mathbf{R}$, then T and any decomposition of the identity $\{E(\lambda)\}_{\lambda \in \mathbf{R}}$ associated with T are related by the condition that

$$\langle Tx, x^* \rangle = b \langle x, x^* \rangle - \int_a^b \langle x, E(\lambda)x^* \rangle d\lambda$$

for all $x \in X$ and $x^* \in X^*$. We refer the reader who is not familiar with the above notions to [2] where the theories of spectral and well-bounded operators are fully developed.

In [1], Berkson and Dowson found a condition on the decompositions of the identity associated with a well-bounded operator T which is sufficient to allow one to construct a spectral measure.

Definition. A decomposition of the identity for X $\{E(\lambda)\}_{\lambda \in \mathbb{R}}$ is said to be of bounded variation if the function $\lambda \mapsto \langle x, E(\lambda)x^* \rangle$ is of bounded variation for all $x \in X$ and all $x^* \in X^*$.

Theorem 1 [1, Theorem 5.2]. Suppose that T is a bounded linear operator on a complex Banach space X and that $\sigma(T) \subset \mathbb{R}$. Then the following are equivalent:

- (i) T is well-bounded and possesses a decomposition of the identity of bounded variation;
- (ii) there exists a compact interval $[a, b] \subset \mathbb{R}$ and a constant M such that

$$\|g(T)\| \leq M \sup_{[a, b]} |g|$$

for all polynomials g ;

- (iii) T^* is a scalar-type prespectral operator of class X .

In general it is possible for T to possess a decomposition of the identity of bounded variation without T being scalar-type spectral. However, using the following two facts, Berkson and Dowson showed that this cannot happen if X is weakly complete. On such spaces, every well-bounded operator whose decomposition of the identity is of bounded variation is real scalar-type spectral (i.e., is a scalar-type spectral operator whose spectrum is contained in \mathbb{R}).

Fact 1 [2, Theorem 6.24]. An operator $T \in B(X)$ is scalar-type spectral if and only if it has a weakly compact $\mathcal{E}(\sigma(T))$ functional calculus (i.e., for all $x \in X$, the map $f \mapsto f(T)x$ from $\mathcal{E}(\sigma(T))$ into X is weakly compact).

Fact 2 [3, Theorem VI.7.6]. Let Ω be a compact Hausdorff space. Then every bounded linear operator from $\mathcal{E}(\Omega)$ into a weakly complete Banach space is weakly compact.

The following theorem shows that one can characterize the Banach spaces for which Berkson and Dowson's condition is sufficient for an operator to be scalar-type spectral as exactly those spaces which do not contain c_0 .

Theorem 2. Suppose that X is a complex Banach space. Then the following are equivalent:

- (i) X does not contain a subspace isomorphic to c_0 ;
- (ii) every well-bounded operator on X with a decomposition of the identity of bounded variation is real scalar-type spectral.

Proof. (i) \Rightarrow (ii). this is an easy consequence of Theorem 1, Fact 1 and the fact that every map from the continuous functions on a compact Hausdorff space into a space not containing c_0 is weakly compact [5, Theorem 5].

(ii) \Rightarrow (i). Suppose that X contains a subspace Y which is isomorphic to c_0 . Then Y is also isomorphic to the space c of all convergent sequences. We shall follow the methods of [4] to embed a suitable operator on c into $B(X)$. If we regard Y as being identified with c , we can equip it with either of the two equivalent norms; $\|\cdot\|_\infty$ from c and $\|\cdot\|_X$ from X . We shall assume that $K^{-1}\|\cdot\|_X \leq \|\cdot\|_\infty \leq K\|\cdot\|_X$.

Let $e_n \in Y$ be the element of c which has 1 in the n th position and 0 elsewhere, and let ϕ'_n be the n th coordinate functional on c (i.e., $\langle \sum \alpha_k e_k, \phi'_n \rangle = \alpha_n$). It is easy to check that $|\langle y, \phi'_n \rangle| \leq K\|y\|_X$ for all $y \in Y$. We shall denote by ϕ_n a fixed norm-preserving extension of ϕ'_n to all of X .

Define S on X by $Sx = \sum_{n=1}^{\infty} (1/n)\langle x, \phi_n \rangle e_n$. Note that for $x \in X$, $|\langle x, \phi_n \rangle| \leq K\|x\|_X$, so that $(1/n)\langle x, \phi_n \rangle$ tends to zero as n tends to ∞ . Thus $Sx \in Y$ for all $x \in X$. Now

$$\begin{aligned} \|Sx\|_X &\leq K\|Sx\|_\infty \\ &= K \sup_n |(1/n)\langle x, \phi_n \rangle| \\ &\leq K^2 \sup_n (1/n)\|x\|_X \end{aligned}$$

so S is a bounded operator on X . Indeed, if g is a polynomial then

$$g(S)x = \sum_{n=1}^{\infty} \left(g\left(\frac{1}{n}\right) - g(0) \right) \langle x, \phi_n \rangle e_n + g(0)x.$$

Thus

$$\begin{aligned} \|g(S)x\| &\leq K \sup_n \left| \left(g\left(\frac{1}{n}\right) - g(0) \right) \langle x, \phi_n \rangle \right| + \|g(0)x\|_X \\ &\leq (2K^2 + 1) \sup_{[a,b]} |g| \|x\|_X. \end{aligned}$$

By Theorem 1 then, S is a well-bounded operator which possesses a decomposition of the identity of bounded variation. However, as is shown in [2, Example 14.6], $S|Y$ is not a scalar-type spectral operator. Thus, by [2, Theorem 12.16], S cannot be a scalar-type spectral operator on X .

ACKNOWLEDGMENT

The author would like to express his thanks to Dr. T. A. Gillespie for several helpful discussions regarding this paper.
