DIVERGENCE OF AVERAGES OBTAINED BY SAMPLING A FLOW

MUSTAFA AKCOGLU, ALEXANDRA BELLOW, ANDRES DEL JUNCO, AND ROGER L. JONES

(Communicated by Andrew M. Bruckner)

Abstract. In this paper we consider ergodic averages obtained by sampling at discrete times along a measure preserving ergodic flow. We show, in particular, that if $U_t$ is an aperiodic flow, then averages obtained by sampling at times $n + t_n$ satisfy the strong sweeping out property for any sequence $t_n \to 0$. We also show that there is a flow (which is periodic) and a sequence $t_n \to 0$ such that the Cesaro averages of samples at time $n + t_n$ do converge a.e. In fact, we show that every uniformly distributed sequence admits a perturbation that makes it a good Lebesgue sequence.

Let $(X, \Sigma, m, U)$ denote a dynamical system, where $(X, \Sigma, m)$ is a probability space and $U = \{U_t : t \in \mathbb{R}\}$ is an ergodic measure preserving flow acting on $X$. Let $(n_k)_{k=1}^{\infty}$ be any increasing sequence of integers and let $(t_k)_{k=1}^{\infty}$ be a sequence of numbers converging to zero. Define the averaging operators $C_N$ by

$$C_N f(x) = \frac{1}{N} \sum_{k=1}^{N} f(U_{n_k + t_k} x).$$

We will be concerned with the almost everywhere convergence properties of this sequence of operators.

If the sequence $(t_k)_{k=1}^{\infty}$ is chosen to be linearly independent over the rationals, then using Bourgain's entropy method, Bergelson, Boshernitzan, and Bourgain showed that these averages can diverge a.e. even for $f \in L^\infty$ [4]. In fact, using a result of Rosenblatt [9], their result implies that in the case of an aperiodic flow there is a positive constant $\delta$, which depends only on the sequence $(n_k + t_k)$, such that given $\varepsilon > 0$, we can take $f = \chi_A$ for some set $A$ with $m(A) < \varepsilon$ and $\limsup C_N f(x) > \delta$ a.e.

In what follows we shall consider the circle group $[0, 1)$ (mod 1). When there is no ambiguity, we shall simply write $[0,1)$.

Throughout the paper we will use the notation $\{x\}$ to denote the fractional part of $x$, i.e., $\{x\} = x - [x]$. Lebesgue measure of a set $A$ will be denoted by $\mu(A)$.

A sequence of operators, $M_k$, on a probability space is said to have the "strong sweeping out property" if given $\epsilon > 0$, there exist a set $A$, with $m(A) < \epsilon$, such that $\limsup M_k \chi_A = 1$ a.e. and $\liminf M_k \chi_A = 0$ a.e.

Clearly a sequence of operators that satisfies the "strong sweeping out property" is very badly behaved.

Using results by Jones and Wierdl [7], it is easy to see that in the special case when $(t_k)$ are linearly independent over the rationals, the averaging operators $C_n$ have the "strong sweeping out property". However, much more is true!

**Theorem 1.** For any sequence $(t_k)_{k=1}^{\infty}$ that converges to zero and any aperiodic flow, the averaging operators $C_n$ have the strong sweeping out property.

The proof of this fact will consist of first proving a local ergodic theorem on a special flow on the circle group $[0, 1)$ (mod 1), then proving the failure of a maximal inequality on an interval $[0, L) \subset \mathbb{R}$, with translation, and finally a transference of this maximal function property to the setting of a general flow via a continuous version of the Rohlin lemma. We begin with the following local ergodic theorem.

**Theorem 2.** Let $(t_k)_{k=1}^{\infty}$ be any sequence that converges to zero, and define the averaging operators $T_N$ by $T_Nf(x) = \frac{1}{N} \sum_{k=1}^{N} f(x + t_k)$ for $f: [0, 1) \to [0, 1)$. Then the operators $T_N$ have the strong sweeping out property.

**Remark.** Weaker versions of this lemma are known. Bourgain [5] showed that these operators have unbounded metric entropy and hence fail to converge a.e. even for $f \in L^\infty$. Rosenblatt [9] noticed that this implies "$\delta$ sweeping out". Akcoglu, del Junco, and Lee [1] proved "$\delta$ sweeping out" without using the entropy method. In [3] the methods of Akcoglu, del Junco, and Lee are used to prove that in fact we have strong sweeping out. We refer the interested reader to that paper for the proof.

**Theorem 3.** Let $(t_k)_{k=1}^{\infty}$ converge to zero and let $(n_k)_{k=1}^{\infty}$ be any increasing sequence of integers. Define the operators

$$\tilde{T}_N f(t) = \frac{1}{N} \sum_{k=1}^{N} f(t + n_k + t_k)$$

for $f: \mathbb{R} \to \mathbb{R}$. Then for every $\epsilon > 0$ and $K > 0$, there is an $L > 0$ and a set $A \subset [0, L]$ that satisfies

(a) $\mu(A)/L < \epsilon$ and

(b) $\mu\{t \in [0, L) : \sup_{n > K} \tilde{T}_n \chi_A(t) > 1 - \epsilon\} > L(1-\epsilon)^2$.

(Here $\mu(A)$ denotes the Lebesgue measure of the set $A$.)

**Proof.** We can assume without loss of generality that $|t_k| < 1$. First note that given $\epsilon > 0$ we can find a set $E$ such that $\mu(E) < \epsilon$, but such that the operators $T_N$ have the strong sweeping out property on $[0, 1)$ (mod 1). Define the set $P$ by $\chi_P = \chi_E$ on $[0, 1)$ and extend $P$ so that $\chi_P$ is periodic with period 1 on...
all of \( R \). Define \( \chi_A = \chi_{F \chi_{[0,L)}} \). Consequently if \( t \in [1, L - n_N - 1) \) then

\[
\bar{T}_N \chi_A(t) = \frac{1}{N} \sum_{k=1}^{N} \chi_A(t + n_k + t_k) = \frac{1}{N} \sum_{k=1}^{N} \chi_A(t + t_k) = \frac{1}{N} \sum_{k=1}^{N} \chi_A(t_k) = T_N \chi_A(x).
\]

Because we know \( \sup_{K, N < M} T_N \chi_A = 1 \) a.e. on \([0, 1) \) (mod 1), we can find an integer \( M \) so that

\[
\mu \left( \left\{ \sup_{K, N \leq M} T_N \chi_A > 1 - \varepsilon \right\} \right) > 1 - \varepsilon.
\]

Select \( L \) so large that \( (L - n_M - 2)/L > 1 - \varepsilon \). Consequently, we have

\[
\mu \left( \left\{ t \in [1, L - n_M - 1): \sup_{K, N \leq M} T_N \chi_A > 1 - \varepsilon \right\} \right) > (1 - \varepsilon)(L - n_M - 2) > (1 - \varepsilon)^2 L.
\]

Thus the set \( A \) satisfies the conditions required for Theorem 3. \( \square \)

**Proof of Theorem 1.** Theorem 1 now follows from Theorem 2 and an application of a continuous version of the Rohlin tower construction. From the Rohlin tower construction \([8]\) we know that given \( \varepsilon > 0 \) and \( L \), there is a set \( B \) such that

(i) the sets \( U_tB \) are disjoint for \( t, 0 \leq t < L \), and \( Y = \bigcup_{0 \leq t < L} U_tB \) is measurable in \( X \).

(ii) \( m(U_{0 \leq t < L} U_tB) > 1 - \varepsilon \).

(iii) Let \( Q \) be the interval \([0, L) \) with Lebesgue measure \( \mu \) and let \( \phi : B \times Q \to Y \) be the natural bijection defined by \( \phi(x, t) = U_t x \). Then there is a measure \( m_B \) on the set \( B \) (which is singular with respect to the given measure \( m \) on \( X \)) such that both \( \phi \) and \( \phi^{-1} \) are measurable measure-preserving maps between \((B \times Q, m_B \times \mu)\) and \((Y, m)\). In particular,

\[
1 - \varepsilon < \int_B L d m_B(x) < 1.
\]

Let \( F = X - \bigcup_{0 \leq t < L} U_tB \).

Define a function \( f : X \to X \) as follows: on each "fiber"

\[
f(U_tx) = \chi_A(t) \quad \text{for} \ 0 \leq t < L \ \text{and} \ x \in B,
\]

and \( f = 0 \) on \( F \). We have

\[
\|f\|_1 = \int_X f(x) \, dm(x) = \int_Y f(y) \, dm(y) + \int_F f(x) \, dm(x)
\]

\[
= \int_B \int_0^L f(U_t x) \, d \mu(t) \, dm_B(x) \leq \int_B \varepsilon L \, dm_B(x) < \varepsilon,
\]
and we have
\[
m \left( \{ y \in Y : \sup_{K < N \leq M} C_N f(y) > 1 - \varepsilon \} \right) \\
\geq \int_B \int_1^{L - n_M - 1} \chi_{\{ \sup_{k < N \leq M} T_N x_k > 1 - \varepsilon \}}(t) \, dt \, dm_B(x) \\
\geq \int_B (1 - \varepsilon)^2 \, d \mu_B(x) > (1 - \varepsilon)^2 (1 - \varepsilon) = (1 - \varepsilon)^3.
\]

We can now apply a well-known result of del Junco and Rosenblatt [6] that says that if for each \( \varepsilon > 0 \) and \( K \), we can find a set \( A \) such that \( \sup_{n > K} C_N 1_A > 1 - \varepsilon \) on a set of measure at least \( 1 - \varepsilon \), then the sequence \( C_n \) has the “strong sweeping out property”.

In order to make the above argument work, it is important to have an aperiodic transformation. Otherwise it is not possible to make the necessary Rohlin tower. In fact, in the periodic case, Theorem 1 is false. We have the following result.

**Theorem 4.** Let \((X, \Sigma, m, U)\) be the dynamical system consisting of the unit interval with Lebesgue measure and \( U \) the measure preserving ergodic flow \( U t x = x + \theta t \mod 1 \), with \( \theta \) irrational. For this dynamical system we can find a sequence \((p_k)_{k=1}^\infty\) with the property that \( \lim_{k \to \infty} p_k = 0 \), \( p_k \neq 0 \) for any \( k \), but such that the averages
\[
\lim_{N \to \infty} \frac{1}{N} \sum_{k=1}^N f(U_{k+p_k} x)
\]
converge a.e. for all \( f \in L^1(X) \).

Theorem 4 will be a special case of the following theorem, which in a certain sense provides an answer to a question raised in [2].

**Theorem 5.** Let \((s_n)_{n=0}^\infty\) be uniformly distributed in \([0, 1)\). Then there is a sequence \((\varepsilon_n)_{n=0}^\infty\), \( \varepsilon_n \neq 0 \) for all \( n \), \( \varepsilon_n \to 0 \), such that \((s_n + \varepsilon_n)_{n=0}^\infty\) is good Lebesgue, i.e., for all \( f \in L^1 \),
\[
\frac{1}{N} \sum_{n=0}^N f(\{ x + s_n + \varepsilon_n \}) \to \int f \, d\mu \quad \text{a.e.}
\]

We divide the proof into several lemmas.

**Definition 1.** The \( n \)-tuple \((u_0, u_1, \ldots, u_{n-1})\) is called \( 2^m \)-good if for all dyadic intervals of order \( 2^m \), \( I = [r/2^m, s/2^m) \),
\[
\left| \frac{1}{n} \sum_{i=0}^{n-1} \chi_I(u_i) - \mu(I) \right| < \frac{1}{2^{m+1}}.
\]

**Lemma 1.** Let \((x_n)_{n=0}^\infty\) be uniformly distributed \( \mod 1 \). For each integer \( m \geq 1 \), there exists \( n_1 \geq 1 \) such that \( n \geq n_1 \) implies \((x_n, x_{n+1}, \ldots, x_{2n-1})\) is \( 2^m \)-good.

**Proof.** This follows easily from the definitions.
Lemma 2. Suppose $n = k2^m$ and that the $n$-tuple $(u_0, u_1, \ldots, u_{n-1})$ is $2^m$-good. Let $(u_0', u_1', \ldots, u_{n-1}')$ be a nondecreasing rearrangement of $(u_0, u_1, \ldots, u_{n-1})$. Then

$$|u_i' - \left\lfloor \frac{i}{k} \right\rfloor \frac{1}{2^m}| < \frac{2}{2^m}.$$

Proof. For $0 < j < 2^m$, note that

$$\sum_{i=0}^{n-1} \chi_{[0, j/2^m)}(u_i) \geq n \left( \frac{j}{2^m} - \frac{1}{2^m+1} \right) = kj - k > kj - k = (j-1)k$$

and, similarly,

$$\sum_{i=0}^{n-1} \chi_{[0, j/2^m)}(u_i) < (j+1)k;$$

thus

$$u_{(j-1)k} < \frac{j}{2^m} \quad \text{and} \quad u_{(j+1)k} \geq \frac{j}{2^m},$$

whence

$$\frac{j-1}{2^m} \leq u_{jk} < \frac{j+1}{2^m}.$$

It follows that for $0 \leq r < k$,

$$\frac{j-1}{2^m} \leq u_{j(k+r)} \leq u_{(j+1)k} < \frac{j+2}{2^m}$$

and for $i = jk + r$, $[i/k] = j$. Note also that for $j = 1$,

$$0 \leq u_1 < \frac{1+1}{2^m} = \frac{2}{2^m},$$

hence for $0 \leq r < k$, $[r/k] = 0$ and $u_1 \leq 2/2^m$. This finishes the proof. \hfill \Box

Lemma 3. Suppose $n = k2^m$ and the $n$-tuples $(u_0, u_1, \ldots, u_{n-1})$ and $(v_0, v_1, \ldots, v_{n-1})$ are $2^m$-good. Then there exists a permutation $\tau$ of $\{0, 1, \ldots, n-1\}$ such that $|u_i - v_{\tau(i)}| < 4/2^m$ for $i = 0, 1, \ldots, n-1$.

Proof. This result follows immediately from Lemma 2, applied to $(u_0, u_1, \ldots, u_{n-1})$ and $(v_0, v_1, \ldots, v_{n-1})$. \hfill \Box

Lemma 4. Let $(u_n)$ be a sequence in $[0, 1)$ and define

$$A_Nf(x) = \frac{1}{N} \sum_{i=0}^{N-1} f(x + u_i) \quad \text{for } f \in L^1.$$

Suppose that $N_1 < N_2 < \cdots$ satisfies $N_{i+1} < DN_i$ for some constant $D > 0$ and that there is a maximal inequality

$$\mu \left( \left\{ \sup_i A_N f > \lambda \right\} \right) \leq \frac{C}{\lambda} \|f\|_1 \quad \text{for } f \in L^1_+. $$

Then

$$\mu \left( \left\{ \sup_N A_N f > \lambda \right\} \right) \leq \frac{cD}{\lambda} \|f\|_1 \quad \text{for } f \in L^1_+. $$

Proof. This is easy and well known.
Proof of Theorem 5. First choose an irrational \( \alpha \in [0, 1) \) such that the sets \( \{(n + 1)\alpha : n = 0, 1, \ldots\} \) and \( \{s_m : m = 0, 1, \ldots\} \) are disjoint. (This is possible since there are at most countably many \( \alpha \)’s for which \( \{(n + 1)\alpha : n = 0, 1, \ldots\} \cap \{s_m : m = 0, 1, \ldots\} \neq \emptyset \).) Set \( t_n = ((n + 1)\alpha) \). Now define the increasing sequence of integers

\[
N_1^{(1)} < N_2^{(1)} < \cdots < N_{k_1}^{(1)} < N_2^{(2)} < \cdots < N_{k_2}^{(2)} < \cdots < N_{k_m}^{(m)} < \cdots
\]

as follows:

If \( m \geq 1 \) and \( 1 \leq j < k_m \) then \( N_{j+1}^{(m)} = 2N_j^{(m)} \), and if \( j = k_m \) then \( N_1^{(m+1)} = 2N_{k_m}^{(m)} \).

Choose \( N_1^{(1)} = n_0 \), an even integer with the property that

\[
n \geq n_0 \quad \text{implies} \quad (s_n, s_{n+1}, \ldots, s_{2n-1}) \text{ is } 2^1\text{-good and}
\]

\[
(t_n, t_{n+1}, \ldots, t_{2n-1}) \text{ is } 2^1\text{-good.}
\]

Assume \( N_1^{(m)} \) is defined and \( N_{i+1}^{(m)} = 2N_i^{(m)} \) and choose \( k_m \geq m + 1 \) large enough that for \( N_{i+1}^{(m+1)} = 2N_{k_m}^{(m)} = 2^{k_m}N_1^{(m)} \) we have

\[
n \geq N_1^{(m+1)} \quad \text{implies} \quad (s_n, s_{n+1}, \ldots, s_{2n-1}) \text{ is } 2^{(m+1)}\text{-good and}
\]

\[
(t_n, t_{n+1}, \ldots, t_{2n-1}) \text{ is } 2^{(m+1)}\text{-good.}
\]

For \( m \geq 1 \) and \( 1 \leq j \leq k_m \) define the block of consecutive integers \( B_j^{(m)} \) of length \( N_j^{(m)} \):

\[
B_j^{(m)} = \{N_j^{(m)}, N_j^{(m)} + 1, N_j^{(m)} + 2, \ldots, 2N_j^{(m)} - 1\}.
\]

By Lemma 3, there is a permutation \( \tau = \tau_j^{(m)} \) of the block \( B_j^{(m)} \) such that

\[
|t_i - s_{\tau(i)}| < 4/2^m \quad \text{for } i \in B_j^{(m)}.
\]

With \( \epsilon_{\tau(i)} = t_i - s_{\tau(i)} \), we have

(1) \[ \epsilon_i \neq 0 \quad \text{and} \quad |\epsilon_i| < 4/2^m \quad \text{for all } i \in B_j^{(m)}. \]

For \( m \geq 1 \) and \( 1 \leq j \leq k_m \), note that if \( f \in L^1 \) then

(2) \[
\sum_{n=n_0}^{N_j^{(m)}-1} f(x + s_n + \epsilon_n) = \sum_{n=n_0}^{N_j^{(m)}-1} f(x + t_n)
\]

(since we are summing on complete consecutive blocks \( B_q^{(p)} \) and on each one of these blocks the sum is independent of the order of summation); note also that because of (1), we have \( \epsilon_n \to 0 \).

Because of (2), an application of Lemma 4 now yields the maximal inequality for the averages

\[
A_Nf(x) = \frac{1}{N} \sum_{n=0}^{N-1} f(x + s_n + \epsilon_n), \quad f \in L^1.
\]
DIVERGENCE OF AVERAGES OBTAINED BY SAMPLING A FLOW

Since the sequence \((s_n + \varepsilon_n)\) is also uniformly distributed \(\text{mod } 1\), there is also a dense class—namely, the continuous functions on \([0, 1)\)—for which a.e. convergence obtains. This completes the proof. □
