ON AN OPTIMALITY PROPERTY OF RAMANUJAN SUMS

GENNADY BACHMAN

(Communicated by William W. Adams)

ABSTRACT. We evaluate $\inf_{b_n} \sum_{a=1}^q |\sum_{\substack{n=1\\(n,q)=1}}^q b_n e^{2\pi i a n/q}|$, where the inf is taken over sequences b_n satisfying $b_n \geq 1$. In particular we show that it is attained by taking $b_n = 1$ for all n, which reduces the summation over n to a Ramanujan sum $c_q(a) = \sum_{\substack{n=1\\(n,q)=1}}^q e^{2\pi i a n/q}$.

Let a positive integer q be fixed. In this note we consider the problem of determining

$$\inf_{b_n} \sum_{a=1}^{q} \left| {\sum_n}' b_n e\left(\frac{an}{q}\right) \right|, \tag{1}$$

where $e(\alpha)$ stands for $e^{2\pi i \alpha}$, ${\sum_n}'$ denotes the summation over n in the range $1 \leq n \leq q$, $(n,q) = 1$, and the infimum is taken over all sequences b_n satisfying

$$b_n \geq 1. \tag{2}$$

We note that if $b_n = 1$ for all n, the innermost sum in (1) is the Ramanujan sum

$$c_q(a) = {\sum_n}' e\left(\frac{an}{q}\right).$$

Using the well-known identity

$$c_q(a) = \frac{\varphi(q)\, \mu\left(q/(a,q)\right)}{\varphi\left(q/(a,q)\right)}, \tag{3}$$

where φ and μ are Euler's and Möbius functions respectively (see, for example, [HW, Theorem 272]), and letting $q_0 = \prod_{p|q} p$ be the square-free kernel of q, we obtain

$$\begin{aligned} \sum_{a=1}^{q} |c_q(a)| &= \sum_{a=1}^{q} \frac{\varphi(q)\mu^2\left(q/(a,q)\right)}{\varphi\left(q/(a,q)\right)} \\ &= \varphi(q) \sum_{d|q_0} \frac{1}{\varphi(d)} \sum_{\substack{1\leq a\leq q\\(a,q)=q/d}} 1 = \varphi(q) \sum_{d|q_0} 1 \\ &= \varphi(q) 2^{\omega(q)}, \end{aligned} \tag{4}$$

where $\omega(q)$ is the number of distinct prime divisors of q. Thus (4) gives a "trivial" upper bound for (1). In fact this author was led to consider this problem while

working on estimates for more general exponential sums in an attempt to beat this estimate by introducing a "smoothing factor" b_n which had to satisfy (2). This might seem plausible at first since if $q/(a,q) > 3$, one can easily find b_n satisfying (2) for which

$$\sum\nolimits_n' b_n e\left(\frac{an}{q}\right) = 0.$$

We will show however that (1) is attained by taking $b_n = 1$ for all n. In fact, the following more general result is no more difficult.

Theorem. *Let r be a real number satisfying $r \geq 1$. Then for any sequence of complex numbers b_n we have*

$$\sum_{a=1}^{q} \left|\sum\nolimits_n' b_n e\left(\frac{an}{q}\right)\right|^r \geq \left(\frac{\left|\sum_n' b_n\right|}{\varphi(q)}\right)^r \sum_{a=1}^{q} |c_q(a)|^r . \tag{5}$$

Proof. We may assume that b_n is defined for all integers n and is periodic with period q. We set

$$B = \sum\nolimits_n' b_n$$

and

$$S = \sum_{a=1}^{q} \left|\sum\nolimits_n' b_n e\left(\frac{an}{q}\right)\right|^r .$$

Using n^* to denote the multiplicative inverse of n modulo q for $(n,q)=1$, we write

$$\begin{aligned} |B|^r \sum_{a=1}^{q} |c_q(a)|^r &= \sum_{a=1}^{q} |Bc_q(a)|^r \\ &= \sum_{a=1}^{q} \left|\sum\nolimits_m' \left(\sum\nolimits_n' b_{mn}\right) e\left(\frac{am}{q}\right)\right|^r \\ &= \sum_{a=1}^{q} \left|\sum\nolimits_n' \sum\nolimits_m' b_{mn} e\left(\frac{an^*mn}{q}\right)\right|^r . \end{aligned}$$

By the Hölder inequality, or trivially in the case $r=1$, the last summation over n is bounded by

$$\leq \varphi(q)^{1/r'} \left(\sum\nolimits_n' \left|\sum\nolimits_m' b_{mn} e\left(\frac{an^*mn}{q}\right)\right|^r\right)^{1/r},$$

where r' satisfies $1/r + 1/r' = 1$. Therefore

$$\begin{aligned} |B|^r \sum_{a=1}^{q} |c_q(a)|^r &\leq \varphi(q)^{r/r'} \sum\nolimits_n' \sum_{a=1}^{q} \left|\sum\nolimits_m' b_{mn} e\left(\frac{an^*mn}{q}\right)\right|^r \\ &= \varphi(q)^{r/r'+1} S \\ &= \varphi(q)^r S, \end{aligned}$$

and the theorem follows. ∎

We observe that (5) may fail for $r < 1$. For example, taking $q = 5$, $b_1 = b_4 = 1 + 1/(2\cos(2\pi/5))$ and $b_2 = b_3 = 1$, we obtain, by (3),

(6)
$$\sum_{a=1}^{5}\left|\sum_{n=1}^{4} b_n e\left(\frac{an}{5}\right)\right|^r = \sum_{a=1}^{4}\left|\frac{1}{2\cos(2\pi/5)}\left(e\left(\frac{a}{5}\right)+e\left(\frac{4a}{5}\right)\right)-1\right|^r + \left|4+\frac{1}{\cos(2\pi/5)}\right|^r$$
$$= 2\left|\frac{\cos(4\pi/5)}{\cos(2\pi/5)}-1\right|^r + \left|4+\frac{1}{\cos(2\pi/5)}\right|^r,$$

and

$$\sum_{a=1}^{5}|c_q(a)|^r = 4 + 4^r. \tag{7}$$

Thus for $r > 0$ sufficiently small (6) will be smaller than (7).
