SOME PROPERTIES OF ORDINARY SENSE SLICE 1-LINKS:
SOME ANSWERS TO PROBLEM (26) OF FOX

EIJI OGASA

(Communicated by Ronald A. Fintushel)

Abstract. We prove that, for any ordinary sense slice 1-link \( L \), we can define the Arf invariant, and \( \text{Arf}(L) = 0 \). We prove that, for any \( m \)-component 1-link \( L_1 \), there exists a 3m-component ordinary sense slice 1-link \( L_2 \) of which \( L_1 \) is a sublink.

1. Introduction and main results

In [3] Fox submitted the following problem about 1-links. Note that “slice link” in the following problem is now called “ordinary sense slice link,” and “slice link in the strong sense” is now called “slice link” by knot theorists.

Problem 26 of [3]. Find a necessary condition for \( L \) to be a slice link; a slice link in the strong sense.

Our purpose is to give some answers to the first part of this problem. The latter half is not discussed here. The latter half seems discussed much more often than the first half. See e.g. [2], [5] and [14].

We review the definitions of ordinary sense slice links and of slice links, which we now use.

We suppose \( m \)-component 1-links are oriented and ordered.

Let \( L = (K_1, \ldots, K_m) \) be a \( m \)-component 1-link in \( S^3 = \partial B^4 \). \( L \) is called a slice 1-link, which is “a slice link in the strong sense” in Fox’s terminology, if there exist 2-discs \( D_i^2 \) (\( i = 1, \ldots, m \)) in \( B^4 \) such that \( D_i^2 \cap \partial B^4 = \partial D_i^2 \), \( D_i^2 \cap D_j^2 = \emptyset \) (\( i \neq j \)), and \( (\partial D_1^2, \ldots, \partial D_m^2) \) in \( \partial B^4 \) defines \( L \).

Take a 1-link \( L \) in \( S^3 \). Take \( S^4 \), and regard \( S^4 \) as \( (\mathbb{R}^3 \times \mathbb{R}) \cup \{ \infty \} \). Regard the 3-sphere \( S^3 \) as \( \mathbb{R}^3 \cup \{ \infty \} \) in \( S^4 \). \( L \) is called an ordinary sense slice 1-link, which is “a slice link” in Fox’s terminology, if there exists an embedding \( f : S^2 \hookrightarrow \mathbb{R}^3 \times \mathbb{R} \) such that \( f \) is transverse to \( \mathbb{R}^3 \times \{ 0 \} \) and \( f(S^2) \cap (\mathbb{R}^3 \times \{ 0 \}) \) in \( \mathbb{R}^3 \times \{ 0 \} \) defines \( L \).

Suppose \( f \) defines a 2-knot \( X \). Then \( L \) is called a cross-section of the 2-knot \( X \).

From now on we use the terms in their currently accepted senses.

Ordinary sense slice 1-links have the following properties.
Theorem 1.1. Let \( L \) be an ordinary sense slice 1-link. Then the following hold.

(1) \( L \) is a proper link.
(2) \( \text{Arf}(L) = 0 \).

Note. Although our proof proves (1) and (2) simultaneously, once (1) is known (2) follows easily from the known result that a proper link which is an ordinary sense slice link has trivial Arf invariant. See e.g. [4], [9], [16] and [19].

Theorem 1.2. For any \( m \)-component 1-link \( L \), there exists a \( 3m \)-component ordinary sense slice 1-link \( L' \) of which \( L \) is a sublink.

Note. When \( L \) is not slice and \( m=1 \), it is obvious that ‘\( 3m \)’ is best possible. When \( m \geq 2 \), ‘\( 3m \)’ is not best possible even if no components of \( L \) are slice knots. See the example for Note 3.3 and Figure IV in §3.

Theorem 1.2 follows from Theorem 1.3 obviously.

Theorem 1.3. For any \( m \)-component 1-link \( L=(K_1, ..., K_m) \), there exist an embedding \( f : S^3_1 \coprod ... \coprod S^3_m \hookrightarrow \mathbb{R}^3 \times \mathbb{R} \) and a \( 3m \)-component 1-link \( L' \) with the following properties.

(1) \( f \) is transverse to \( \mathbb{R}^3 \times \{0\} \), and \( f(S^3_i \coprod ... \coprod S^3_m) \cap (\mathbb{R}^3 \times \{0\}) \) in \( \mathbb{R}^3 \times \{0\} \) defines \( L' \).
(2) \( L \) is a sublink of \( L' \).
(3) \( K_i \subset f(S^3_i) \) (\( i = 1, ..., m \)).

This paper is organized as follows. In §2 we prove Theorem 1.1 by using a result of the author’s [17]. In §3 we review Suzuki-Terasaka diagrams of 1-links and the fact that any 1-link has a Suzuki-Terasaka diagram (Theorem 3.1). We use this diagram to prove Theorem 1.3 and Theorem 3.2.

2. The proof of Theorem 1.1

In order to prove Theorem 1.1, we review a result of the author in [17].

Definition. \( T = (L_1, L_2, X_1, X_2) \) is called a 4-tuple of links if the following conditions (1), (2) and (3) hold.

(1) \( L_i = (K_{i1}, ..., K_{im_i}) \) is an oriented ordered \( m_i \)-component 1-dimensional link (\( i = 1, 2 \)).
(2) \( m_1 = m_2 \).
(3) \( X_i \) is an oriented 3-knot.

Definition. A 4-tuple of links \( (L_1, L_2, X_1, X_2) \) is said to be realizable if there exists a smooth transverse immersion \( f : S^3_1 \coprod S^3_2 \hookrightarrow S^5 \) satisfying the following conditions (1) and (2).

(1) \( f|S^3_i \) is a smooth embedding and defines the 3-knot \( X_i \) (\( i = 1, 2 \)) in \( S^5 \).
(2) For \( C = f(S^3_1) \cap f(S^3_2) \), the inverse image \( f^{-1}(C) \) in \( S^3_1 \) defines the 1-link \( L_i \) (\( i = 1, 2 \)). Here, the orientation of \( C \) is induced naturally from the preferred orientations of \( S^3_1, S^3_2 \), and \( S^5 \), and an arbitrary order is given to the components of \( C \).

The following theorem characterizes the realizable 4-tuples of links.

Theorem 2.1. A 4-tuple of links \( T = (L_1, L_2, X_1, X_2) \) is realizable if and only if \( T \) satisfies one of the following conditions i) and ii).
Both $L_1$ and $L_2$ are proper links, and

$$\text{Arf}(L_1) = \text{Arf}(L_2).$$

ii) Neither $L_1$ nor $L_2$ is proper, and

$$\text{lk}(K_{1j}, L_1 - K_{1j}) \equiv \text{lk}(K_{2j}, L_2 - K_{2j}) \mod 2 \quad \text{for all } j.$$  

Note. In [18], the author discussed a high-dimensional version of Theorem 2.1.

**Proof of Theorem 1.1.** Take $f : S^2 \hookrightarrow \mathbb{R}^3 \times \mathbb{R}$ such that $L$ is a cross-section of the 2-knot defined by $f$.

Regard $\mathbb{R}^3 \times \mathbb{R}$ as $\mathbb{R}^3 \times \mathbb{R} \times \{0\} \subset \mathbb{R}^3 \times \mathbb{R} \times \mathbb{R}$. Make $S^5$ from $\mathbb{R}^3 \times \mathbb{R} \times \mathbb{R}$ by the one-point compactification. Here, the 4-sphere $S^4$ is $(\mathbb{R}^3 \times \mathbb{R} \times \{0\} \cup \{\infty\}) \subset S^5 = (\mathbb{R}^3 \times \mathbb{R} \times \mathbb{R} \cup \{\infty\})$. There exists a 3-knot $X_1$ in $\mathbb{R}^3 \times \mathbb{R} \times \mathbb{R}$ such that $X_1 \cap \mathbb{R}^3 \times \mathbb{R} \times \{0\}$ coincides with $f(S^2)$, because all 2-knots are slice by a theorem of Kervaire in [10]. $(\mathbb{R}^3 \times \{0\} \times \{0\}) \cup \{\infty\}$ in $S^5$ is called a 3-knot $X_2$. An immersion $g : S^3_1 \sqcup S^3_2 \rightarrow S^5$ such that $g(S^3_1)$ coincides with the above $X_1$ ($i = 1, 2$) realizes a pair of 1-links $(X_1 \cap X_2)$ in $X_1$, $X_1 \cap X_2$ in $X_2$). Here, it is obvious that $X_1 \cap X_2$ in $X_1$ is the trivial 1-link and $X_1 \cap X_2$ in $X_2$ is $L$. Therefore, by Theorem 2.1, $L$ is a proper link and $\text{Arf}(L)$=0.

\[ \square \]

3. The Proof of Theorem 1.3

We first review the following canonical diagrams of 1-links.

Take an $m$-component 1-link $L$. The set $X$ in $\mathbb{R}^3 = \{(x, y, z)\} \subset \mathbb{R}^3$ defining $L$ is called a Suzuki-Terasaka (canoncal) diagram of $L$ if $X$ is made as follows. Let $Y_i$ ($i = 1, \ldots, m$) be the boundary of $\{(x, y, z) | i \leq x \leq (i+0.9), 0 \leq y \leq 1, z = 0\}$. Let $P_{ij}$ ($j = 1, \ldots, \mu_i$) be the boundary of $\{(x, y, z) | x = \frac{1}{\mu_i+1} i, 0.9 \leq y \leq 1.1, 0 \leq z \leq 0.1\}$. (The orientation of $P_{ij}$ is given appropriately; they are not all the same, in general.) Let $A_{ij} = \{(x, y, z) | \frac{2i-1}{2\mu_i+1} + i \leq x \leq \frac{2i+1}{2\mu_i+1} + i, y = 0, z = 0\}$. Let $\sum_i \mu_i = \sum_i \nu_i$; put $\lambda$ equal to this number. Take bands $B_l$ ($l = 1, \ldots, \lambda$) and make a band-sum of $Y_i$ and $P_{ij}$ by connecting $P_{ij}$ and $A_{i'j'}$ by $B_l$. (Of course $(i, j)$ does not necessarily coincide with $(i', j')$, and the set of $(i, j)$ coincides with the set of $(i', j')$.) Then the band-sum is $X$.

**Theorem 3.1.** Any 1-link has a Suzuki-Terasaka canonical diagram.

The proof of Theorem 3.1 is elementary.

The usefulness of the above canonical diagram was first pointed out by Prof. Shin'ichi Suzuki and Prof. Hidetaka Terasaka. Suzuki-Terasaka canonical diagrams are used, for example, in [15], [23] and [25].

In Figure 1 we give an example of the canonical diagram.

**Proof of Theorem 1.3.** Take a Suzuki-Terasaka canonical diagram of the 1-link $L=(K_1, \ldots, K_m)$ in $\mathbb{R}^3 = \{(x, y, z)\} \subset \mathbb{R}^3$. (See Figure II(1).) Take sets $P_i$ to be $\{(x, y, z) | i \leq x \leq (i+0.9), 1.05 \leq y \leq 2, z = 0\}$. Here, we can take $P_i$ not to intersect with all the bands in the Suzuki-Terasaka canonical diagram. Take sets $S_i$ to be $\{(x, y, z) | i \leq x \leq (i+0.9), -1 \leq y \leq 1, z = 0\}$. Note that $K_i \cap S_i \neq \phi$. (See Figure II(2).) The arc in $K_i$ whose boundary is the points $\{(i, 0, 0)\}$ and $\{(i+0.9, 0, 0)\}$ and which does not include the point $\{(i, 1, 0)\}$ is called $l_i$. Carry

\[ \square \]
out the band-fusion on $S_i$ by using the band $\tilde{B}_i$ whose core is $l_i$. Then $S_i$ splits into two pieces. The one including the point $\{(i,1,0)\}$ is called $Q_i$. The other is called $R_i$. Choose the band along $l_i$ so that $\text{lk}(P_i, R_i) + \text{lk}(Q_i, R_i)=0$. Here $P_i$ and $S_i$ are oriented counterclockwise, and $Q_i$ and $R_i$ are given orientations induced from $S_i$. (See Figure II(3).) Here, note that $(Q_1, ..., Q_m)$ defines the 1-link $L$. Thus we obtain a $3m$-component 1-link $L'$ defined by $(P_1, ..., P_m, Q_1, ..., Q_m, R_1, ..., R_m)$ such that $L$ is a sublink of $L'$.

**Claim.** There exists $f : S_i^2 \ni S_{2m} \hookrightarrow \mathbb{R}^3 \times \mathbb{R}$ such that $f$ is transverse to $\mathbb{R}^3 \times \{0\}$ and $f(S_i^2 \ni S_{2m}) \cap (\mathbb{R}^3 \times \{0\})$ defines the 1-link $L'$.

**Proof.** Construct an embedding $f : S_i^2 \ni S_{2m} \hookrightarrow \mathbb{R}^3 \times \mathbb{R}$ as follows. $f(S_i^2)$ in $\mathbb{R}^3 \times \mathbb{R}$ has two minimum-discs, two saddle-bands and two maximum-discs. The minimum-discs are $h_0^1 = \{(x, y, z) | i \leq x \leq (i + 0.9), -1 \leq y \leq 1, z = 0\} \times \{-2\}$ in $\mathbb{R}^3 \times \{-2\}$ and $h_0^2 = \{(x, y, z) | i \leq x \leq (i + 0.9), 1.05 \leq y \leq 2, z = 0\} \times \{-2\}$ in $\mathbb{R}^3 \times \{-2\}$. The saddle-bands are $B_i \times \{-1\}$ in $\mathbb{R}^3 \times \{-1\}$ and $\{(x, y, z) | i \leq x \leq (i + 0.9), 1 \leq y \leq 1.05, z = 0\} \times \{1\}$ in $\mathbb{R}^3 \times \{1\}$. The maximum-discs are $h_1^1 = \{(x, y, z) | i \leq x \leq (i + 0.9), -1 \leq y \leq -0.1, z = 0\} \times \{2\}$ in $\mathbb{R}^3 \times \{2\}$ and $h_1^2 = \{(x, y, z) | i \leq x \leq (i + 0.9), 0.1 \leq y \leq 2, z = 0\} \times \{2\}$ in $\mathbb{R}^3 \times \{2\}$, where we suppose $\partial B_i$
In order to define knots are discussed in [13], [20], [21], and [22].

Theorem 3.2. For any m-component 1-link \( L = (K_1, ..., K_m) \), there exist an embedding \( g : S^2 \times ... \times I \times S^2 \hookrightarrow \mathbb{R}^3 \times \mathbb{R} \) and a 4m-component 1-link \( L'' \) with the following properties.

1. \( g \) defines the trivial 2-link.
2. \( g \) is transverse to \( \mathbb{R}^3 \times \{0\} \), and \( g(S^2 \times ... \times S^2) \cap (\mathbb{R}^3 \times \{0\}) \) in \( \mathbb{R}^3 \times \{0\} \) defines \( L'' \).
3. \( K_i \subset f(S^2)(i = 1, ..., m) \).

Ordinary sense slice n-knots \((n \geq 1)\) which are cross-sections of the trivial \((n+1)\)-knots are discussed in [13], [20], [21], and [22].

Proof of Theorem 3.2. In order to define \( g \), take the following 2-discs \( D^2 \) in \( \mathbb{R}^3 \times \mathbb{R} \). Take \( f \) in the proof of the above claim. \( f(S^2) \cap \mathbb{R}^3 \times (-1, 2] \) are two components. Take the component of the two which includes \( h^2 \), say \( E_i \).

\( f(S^2) \cap \mathbb{R}^3 \times (-2, 1] \) are two components. Take the component of the two which includes \( h^2 \), say \( E'_i \). Then \( E_i \cup E'_i \) is a submanifold in \( \mathbb{R}^3 \times \mathbb{R} \) diffeomorphic to the 2-disc. We call it \( D^2 \).

Take \( D^2 \times I \) in the tubular neighborhood of \( D^2 \) in \( \mathbb{R}^3 \times \mathbb{R} \). Take \( g \) so that \( g(S^2) \) coincides with \( \partial (D^2 \times I) \) and \( g \) is transverse to \( \mathbb{R}^3 \times \{0\} \). Then \( g(S^2 \times ... \times S^2) \cap (\mathbb{R}^3 \times \{0\}) \) in \( \mathbb{R}^3 \times \{0\} \) is a 4m-component 1-link \( L'' \) and \( L \) is a sublink of \( L'' \).

This completes the proof of Theorem 3.2.

Figure IV illustrates \( g(S^2) \) and \( L'' \) in \( \mathbb{R}^3 \times \mathbb{R} \) in the case where \( L \) is the trefoil knot.

Note 3.3. We can regard Figure IV as the example we mentioned in the note after Theorem 1.2 if we think of \( L \) as a union of \( K_1 \) and \( K_2 \), and of \( L'' \) as a union of \( K_1 \), \( K_2 \), \( K_3 \) and \( K_4 \), where the \( K_i \) are as in Figure IV.

Comparing Theorem 1.3 with Theorem 3.2, it is natural to raise the following problem.
Figure III

Figure I
Problem. Let \( K \) be a non-slice knot. Does there exist a 3-component ordinary sense slice 1-link \( L \) such that \( K \) is a component of \( L \) and \( L \) is a cross-section of the trivial 2-knot?

Note 3.4. After Dr. S. Kamada saw this paper, he solved this problem and obtained a refined version of Theorems 1.3 and 3.2.

ACKNOWLEDGEMENT

When the author asked Prof. Akio Kawauchi whether Theorem 1.1 is new, Prof. Kawauchi answered affirmatively and encouraged the author to write it down. The author would like to thank Prof. Kawauchi for this advice. The author would also like to thank Prof. Shin’ichi Suzuki for valuable discussions, Dr. S. Kamada for the information incorporated in Note 3.4, and Dr. P. Akhmetiev for his interest in making our Theorem 1.1 stronger. He would also like to thank the referee for reading the manuscript patiently.
