ON COMPACT MANIFOLDS
WITH POSITIVE ISOTROPIC CURVATURE

M.-L. LABBI
(Communicated by Józef Dodziuk)

ABSTRACT. In this paper we construct new Riemannian metrics with positive isotropic curvature on compact manifolds which fiber over the circle. We also study the relationship between the positivity of the isotropic curvature and the positivity of the $p$-curvature.

1. INTRODUCTION AND STATEMENT OF RESULTS

Let $(M, g)$ be a Riemannian manifold of dimension $n$. For every $m \in M$ the inner product $g$ on the tangent space at $m$, $T_mM$, extends in two ways to the complexified tangent space $T_mM \otimes \mathbb{C}$:
- as a complex bilinear form, to be denoted by $g(\cdot, \cdot)$,
- as an Hermitian inner product, to be denoted by $\langle \cdot, \cdot \rangle$.

Let $\mathcal{R} : \wedge^2M \to \wedge^2M$ denote the curvature operator of $(M, g)$ and also its complex linear extension to $\wedge^2M \otimes \mathbb{C}$.

To each complex tangent two-plane $P \subset T_mM \otimes \mathbb{C}$ we assign its complex sectional curvature, denoted $K_C(P)$, which is a real number defined by

$$K_C(P) = \frac{\langle \mathcal{R}(v \wedge w), v \wedge w \rangle}{||v \wedge w||^2}$$

where $\{v, w\}$ is any basis of $P$.

A complex vector subspace $P \subset T_mM \otimes \mathbb{C}$ is called isotropic if $g(v, v) = 0$ for all vectors $v \in P$.

**Definition.** A Riemannian manifold $(M, g)$ is said to have positive isotropic curvature if $K_C(P) > 0$ for all two-dimensional isotropic subspaces of $T_mM \otimes \mathbb{C}$ and for every $m \in M$.

Now let $P$ be a complex two-plane and let $(z, w)$ be any basis of $P$. Note that the two-plane $P$ is isotropic if and only if we have

$$g(z, z) = g(w, w) = g(z, w) = 0.$$ 

If furthermore, the basis satisfies

$$g(z, \bar{w}) = 0 \quad \text{and} \quad g(z, \bar{z}) = g(w, \bar{w}) = \sqrt{2}$$

we call \((z, w)\) a standard basis of the isotropic two-plane \(P\). In other words, \((z = e_1 + ie_2, w = e_3 + ie_4)\) is a standard basis for the isotropic plane \(P\) if and only if \(\{e_1, e_2, e_3, e_4\}\) are four orthonormal vectors in the real tangent space to \(M\).

One can check easily from the definition that if \((z = e_1 + ie_2, w = e_3 + ie_4)\) is any standard basis for the isotropic plane \(P\), then

\[
K_C(P) := K_C(z, w) = K(e_1, e_3) + K(e_1, e_4) + K(e_2, e_3) + K(e_2, e_4) - 2\mathcal{R}(e_1, e_2, e_3, e_4).
\]

Now let \(P_1\) (resp. \(P_2\)) denote the real two-plane associated to the complex vector \(z\) (resp. \(w\)), that is, the real plane spanned by the real vectors \(e_1\) and \(e_2\) (resp. \(e_3\) and \(e_4\)). Now if \((e_1', e_2')\) (resp. \((e_3', e_4')\)) is any other orthonormal basis of \(P_1\) (resp. \(P_2\)), then \((z' = e_1' + ie_2', w' = e_3' + ie_4')\) is also a standard basis for the same isotropic two-plane \(P\). Thus, we obtain

\[
K_C(P) = K_C(z, w) = K_C(z', w') = K(e_1', e_3') + K(e_1', e_4') + K(e_2', e_3') + K(e_2', e_4') - 2\mathcal{R}(e_1', e_2', e_3', e_4').
\]

This implies that in formula \((*)\), the isotropic curvature is independent from the choice of the orthonormal basis \((e_1, e_2)\) in \(P_1\) and \((e_3, e_4)\) in \(P_2\).

Hence one can write

\[
K_C(P) = K_C(P_1, P_2)
\]

where \((P_1, P_2)\) is a couple of orthogonal real two-planes in \(P\) (seen as a real four-plane) associated to a standard basis \((z, w)\) of \(P\) as above.

The existence of a metric with positive isotropic curvature on a compact manifold implies strong restrictions on its topology, indeed, Micallef and Moore [MM] proved the following:

**Theorem.** Let \(M\) be a compact \(n\)-dimensional Riemannian manifold \((n \geq 4)\). If \(M\) has positive isotropic curvature, then \(\pi_i(M) = \{0\}\) for \(2 \leq i \leq \lfloor n/2 \rfloor\). In particular, if \(M\) is also simply connected, then \(M\) is homeomorphic to a sphere.

Furthermore, Micallef and Wang [MW], and independently Seaman [Se], proved the following

**Theorem.** If \((M, g)\) is a compact Riemannian manifold of even dimension and with positive isotropic curvature, then \(H^2(M, \mathbb{R}) = 0\).

On the other hand, little is known about examples of compact manifolds with positive isotropic curvature. In this context, Micallef and Wang [MW] proved the following interesting result:

**Theorem.** The connected sum of two manifolds of dimension \(\geq 4\), each one admitting a metric with positive isotropic curvature, admits a metric with positive isotropic curvature.

In this paper, we construct new classes of manifolds with positive isotropic curvature. In Section 2, we study the relation between the positivity of the isotropic curvature and the positivity of the \(p\)-curvature. For example we prove that in the case of conformally flat manifolds the positivity of the \((n - 4)\)-curvature \((n\) is the dimension of the manifold) is equivalent to the positivity of the isotropic curvature, and we deduce many consequences.

In Sections 3 and 4, we prove the following theorems:
Theorem I. Let \( \pi : (M, g) \to S^1 \) be a local Riemannian submersion over the circle, where \( M \) is a compact Riemannian manifold of dimension \( \geq 5 \).

If the fibers of \( \pi \) (endowed with the induced metric) satisfy the positivity condition (A), then the manifold \( M \) admits a metric with positive isotropic curvature, where (A) denotes the following positivity condition for an algebraic curvature tensor:

For all orthonormal vectors \( e_i, e_j, e_k, e_l \), we have

\[
K(e_j, e_k) + K(e_j, e_l) > |R(e_i, e_j, e_k, e_l)|
\]

where \( K \) is its sectional curvature.

Note that the strict pointwise \( \frac{1}{4} \)-pinching condition implies the condition (A), and the condition (A) implies at the same moment the positivity of the isotropic curvature and the positivity of the Ricci curvature. Note also that in the case of conformally flat manifolds and hypersurfaces of the Euclidean space, it is equivalent to the following positivity condition on the sectional curvature:

\[
K(e_j, e_k) + K(e_j, e_l) > 0, \quad \text{for all orthonormal vectors } e_j, e_k, e_l.
\]

In the case of four dimensions, we prove the following similar result:

Theorem II. Let \( \pi : (M, g) \to S^1 \) be a Riemannian submersion over the circle, where \( M \) is a compact Riemannian manifold of dimension 4.

If the fibers of \( \pi \) (endowed with the induced metric) are with positive Ricci curvature, then the manifold \( M \) admits a metric with positive isotropic curvature.

Example. Let \( F \) be any manifold of dim \( \geq 3 \) admitting a metric which satisfies the positivity condition (A) (if \( \dim F = 3 \), we suppose that \( F \) is with positive Ricci curvature), and let \( \phi \in Isom(F) \) and define

\[
\rho : \mathbb{Z} \to Isom(F \times \mathbb{R})
\]

\[
n \mapsto \phi_n(x, t) = (\phi^n(x), t + n).
\]

The manifold \( M = \mathbb{E} \times \mathbb{R} \rho \) is the total space of a Riemannian submersion and satisfies the conditions of Theorem I or II, hence it admits a Riemannian metric with positive isotropic curvature.

As a direct consequence of the proofs of the previous Theorems I and II, we can easily prove the following corollaries:

Corollary I. If a compact manifold of dimension \( \geq 5 \) (resp. of dimension 4) admits a Riemannian foliation of codimension 1 such that the leaves, endowed with the induced metric, satisfy the positivity condition (A) (resp. are with positive Ricci curvature), then it admits a Riemannian metric with positive isotropic curvature.

Corollary II. If a compact manifold \( M \) of dimension 4 admits a free action of \( SU(2) \) or \( SO(3) \), then it admits a Riemannian metric with positive isotropic curvature.

Remarks. 1. This last theorem is not generally true if the action is not supposed to be free. In fact, \( S^2 \times S^2 \) admits an effective action of \( SO(3) \), but no metric with positive isotropic curvature since the second Betti number is not zero.

2. One can immediately obtain from our previous results and the results of Micallef-Moore and Wang well known topological obstructions (such as the annulation of certain homotopy and homology groups) on the existence of Riemannian foliations and group actions on compact manifolds.
2. Positive isotropic curvature and positive $p$-curvature

Let $(M, g)$ be a Riemannian manifold of dimension $n$. Recall that (see [L1], [L2] and [L3]) the $p$-curvature of $(M, g)$, denoted by $s_p$, $0 \leq p \leq n - 2$, is a function defined on the $p$-Grassmannian bundle over $M$, which assigns to every tangent $p$-plane $P$ at $m \in M$ the scalar curvature at $m$ of the Riemannian sub-manifold $\exp_m(V)$, where $V$ is a neighborhood of 0 in $P^\perp$ (the orthogonal to $P$ in $T_mM$), and $\exp_m$ is the exponential map.

For $p = 0$ (resp. $p = n - 2$) it is the scalar curvature (resp. the sectional curvature). Note that the positivity of $s_p$ implies the positivity of $s_k$ for all $k = 0, ..., p - 1$.

**Proposition.** Let $(M, g)$ be an $n$-dimensional Riemannian manifold with positive (resp. nonnegative) isotropic curvature. Then it has positive (resp. nonnegative) $p$-curvature, for all $p \leq n - 4$.

**Proof.** From the formula (*) stated in the introduction, we have

$$K(e_1, e_3) + K(e_1, e_4) + K(e_2, e_3) + K(e_2, e_4) - 2R(e_1, e_2, e_3, e_4) > 0,$$

$$K(e_1, e_4) + K(e_1, e_3) + K(e_2, e_4) + K(e_2, e_3) + 2R(e_1, e_2, e_3, e_4) > 0$$

for all orthonormal tangent vectors $(e_1, e_2, e_3, e_4)$.

It follows that

$$K(e_1, e_3) + K(e_1, e_4) + K(e_2, e_3) + K(e_2, e_4) > 0.$$

By permuting the indices, one can easily check that this implies

$$K(e_1, e_2) + K(e_1, e_3) + K(e_1, e_4) + K(e_2, e_3) + K(e_2, e_4) + K(e_3, e_4) > 0$$

for all orthonormal tangent vectors $(e_1, e_2, e_3, e_4)$, which is nothing but the positivity of the $(n - 4)$-curvature. Consequently, the $p$-curvature is positive, for all $p \leq n - 4$.

Of course we obtain large inequality in the case of nonnegative curvature.

**Remark.** Note that the converse, in the previous proposition, is not generally true. In fact, the product of a sphere of dimension $n - 2$ with a Riemann surface of genus $g \geq 2$ admits a metric with positive $(n - 4)$-curvature (see [L2]), but no metric with positive isotropic curvature, since the second Betti number is not zero.

In the case when $n = 4$, Micallef and Moore (see [MM] and [MWo]) proved that $(M, g)$ has positive isotropic curvature if and only if $\frac{1}{6}s_0 - W > 0$ as an operator on $\wedge^2 M$, where $s_0$ is the scalar curvature and $W$ is the Weil curvature. We can generalize this result to any dimension as follows:

**Proposition.** A Riemannian manifold $(M, g)$ has positive isotropic curvature if and only if for all four-planes $P$ tangent to $M$ we have

$$\frac{1}{6}s_{n-4}(P^\perp) - W > 0$$

as an operator on $\wedge^2 P$, where $s_{n-4}(P^\perp)$ is the $(n - 4)$-curvature of $(M, g)$ and $W : \wedge^2 P \to \wedge^2 P$ is the Weil curvature operator at $m$ of the Riemannian submanifold $\exp_m(V)$, where $V$ is a neighborhood of 0 in $P$.

**Proof.** This follows immediately from the case $n = 4$ after noting that the Riemannian submanifold $\exp_m(V)$ is totally geodesic at $m$ and its dimension is four.
Corollary I. Let \((M, g)\) be a compact conformally flat \(n\)-manifold with positive isotropic curvature. Then \(H^m(M, \mathbb{R}) = 0\) for \(2 \leq m \leq n - 2\).

Corollary II. Let \((M, g)\) be a compact conformally flat \(n\)-manifold with nonnegative isotropic curvature such that \(H^2(M, \mathbb{R}) \neq 0\). Then \((M, g)\) is either flat or covered by \(S^{n-2} \times \mathbb{H}^2\).

Proof. In the case of conformally flat manifolds, the Weil curvature is zero. Consequently, the positivity of the \((n-4)\)-curvature is equivalent to the positivity of the isotropic curvature, and hence, the corollaries are immediate consequences of our similar results on the \(p\)-curvature in [L1].

This generalizes the result of Micallef and Wang [MW] in the case of conformally flat manifolds. This was first proved by S. Nayatani in [Na].

3. Proofs of Theorems I and II

Let \(\pi : (M, g) \to S^1\) be a Riemannian submersion. For all \(m \in M\), the tangent space \(T_mM\) decomposes into

\[ T_mM = V_m \oplus R\tau \]

where \(V_m\) is the subspace of \(T_mM\) tangent to the fiber at \(m\) (called the vertical subspace), and \(\tau\) is the unit vector orthogonal to \(V_m\).

Now let \(g_t, t \in \mathbb{R}\), be the canonical variation of the metric \(g\), that is, a new Riemannian metric defined on \(M\) by (see [Be] and [L2])

\[

g_{t|V_m} = t^2 g_{V_m},
\]

\[
g_{t}(\tau, \tau) = g(\tau, \tau),
\]

\[
g_{t}(V_m, \tau) = 0.
\]

Using the O'Neill formulas for the curvature, one can prove without difficulties the following (see [L2], [Be]).

Lemma. Let \(R_t\) denote the curvature tensor for the metric \(g_t\). For all \(g_t\)-unit vectors \(U_i\) in \(V_m\), we have

\[
R_t(U_1, U_2, U_3, U_4) = \frac{1}{t^2} \hat{R}(tU_1, tU_2, tU_3, tU_4) + O\left(\frac{1}{t}\right),
\]

\[
R_t(U_1, U_2, U_3, \tau) = O\left(\frac{1}{t}\right),
\]

\[
R_t(U_1, \tau, U_2, \tau) = O(1),
\]

where \(\hat{R}\) is the curvature tensor for the induced metric on the fibers from the metric \(g\).

Now let \(P\) be any isotropic two-plane in \((T_mM \otimes C, g_t)\); and let \((P_1, P_2)\) be a couple of orthogonal real two-planes associated to a standard basis of \(P\) (as mentioned in the introduction).

Since \(\dim V_m = n - 1 \geq 3\), and since the isotropic curvature is independent from the choice of the standard basis in \(P\), we can assume that \(P_1\) or \(P_2\) is contained in \(V_m\) (see Lemma below). Suppose for example that \(P_2 \subset V_m\), and then let \((U_2, V_2)\) be any \(g_t\)-orthonormal basis for \(P_2\), such that the vectors \(U_2\) and \(V_2\) are in \(V_m\).

Since now \(\dim (P_1 \cap V_m) \geq 1\), let \(U_1\) be a \(g_t\)-unit vector in \(P_1 \cap V_m\), and \(E_1\) be a \(g_t\)-unit vector orthogonal to \(U_1\) in \(P_1\). Set \(E_1 = \alpha_1 \tau + \beta_1 V_1\), where \(V_1\) is a \(g_t\)-unit vector in \(V_m\). Thus \((U_1, E_1)\) is a \(g_t\)-orthonormal basis for \(P_1\).
The isotropic curvature of the two-isotropic plane $P$ for the metric $g_t$ is then given by

$$Isot_t(P_1, P_2) = K_t(U_1, U_2) + K_t(U_1, V_2) + K_t(E_1, U_2) + K_t(E_1, V_2) - 2R_t(U_1, E_1, U_2, V_2)$$

Using the previous Lemma, we obtain

$$Isot_t(P) = \frac{1}{t^2} \hat{K}(U_1^1, U_2^1) + \frac{1}{t^2} \hat{K}(U_1^2, V_2^1) + \frac{\beta^2}{t^2} \hat{K}(V_1^1, U_2^1) + \frac{\beta^2}{t^2} \hat{K}(V_1^2, V_2^1)$$

$$- \frac{2\beta}{t^2} \hat{R}(U_1^1, V_1^1, U_2^1, V_2^1) + O(\frac{1}{t})$$

where $U_i^j = tU_i$ and $V_i^j = tV_i$ are $g$-unit vectors in $V_m$. It follows that

$$Isot_t(P) \geq \frac{1}{t^2} F(\beta_1) + O(\frac{1}{t})$$

where

$$F(\beta_1) = \hat{K}(U_1^1, U_2^1) + \hat{K}(U_1^2, V_2^1) + \beta^2 \hat{K}(V_1^1, U_2^1) + \beta^2 \hat{K}(V_1^2, V_2^1)$$

$$- 2 \beta \hat{R}(U_1^1, V_1^1, U_2^1, V_2^1).$$

Hence, since $M$ is compact, the isotropic curvature $Isot_t$ will be positive on all $M$ for $t$ small enough, if we have $F(\beta_1) > 0$ for all $0 \leq \beta_1 \leq 1$. Let us now look for the positivity of this function. We have

$$F(0) = \hat{K}(U_1^1, U_2^1) + \hat{K}(U_1^2, V_2^1) > 0, \quad F'(0) = -2 \hat{R}(U_1^1, V_1^1, U_2^1, V_2^1) \leq 0,$$

$$F(1) = Isot(\hat{P}_1, \hat{P}_2) > 0,$$

$$F'(1) = 2(\hat{K}(V_1^1, U_2^1) + \hat{K}(V_1^2, V_2^1)) - 2 \hat{R}(U_1^1, V_1^1, U_2^1, V_2^1) \geq 0.$$ 

If $F'(1) \leq 0$, then $F$ will decrease and then $F(1) > 0$ implies that $F$ is positive $\forall \beta, 0 \leq \beta \leq 1$. Now, if $F'(1) > 0$, that is, $\hat{K}(V_1^1, U_2^1) + \hat{K}(V_1^2, V_2^1) > | \hat{R}(U_1^1, V_1^1, U_2^1, V_2^1) |$, then the function $F$ admits a minimum value at

$$\beta = \frac{| \hat{R}(U_1^1, V_1^1, U_2^1, V_2^1) |}{\hat{K}(V_1^1, U_2^1) + \hat{K}(V_1^2, V_2^1)}.$$

Its value is equal to

$$\hat{K}(V_1^1, U_2^1) + \hat{K}(V_1^2, V_2^1) - \frac{| \hat{R}(U_1^1, V_1^1, U_2^1, V_2^1) |^2}{\hat{K}(V_1^1, U_2^1) + \hat{K}(V_1^2, V_2^1)}.$$

This value is positive if $\hat{K}(V_1^1, U_2^1) + \hat{K}(V_1^2, V_2^1) > | \hat{R}(U_1^1, V_1^1, U_2^1, V_2^1) |$. This is nothing but the condition (A) in our theorem.

**Lemma.** Let $T_mE = V_m \oplus \mathbb{R}t$ as above, where $\dim V_m = n - 1$. Then every isotropic two-plane $P$ in $(T_mE \otimes C, g_t)$ has a standard basis $(z = U_1 + iV_1, w = U_2 + iE_2)$, such that the vectors $U_1, V_1$ and $U_2$ are in $V_m$.

**Proof.** Let $(z = U_1 + iE_1, w = U_2 + iE_2)$ be any standard basis for $P$, and let $(P_1, P_2)$ be the associated couple of orthogonal real two-planes as in the introduction. Since $\dim(P_i \cap V_m) \geq 1$ for $i = 1, 2$, we can assume that $U_1$ and $U_2$ are in $V_m$. 

Now, using a rotation in $T_m M \otimes \mathbb{C}$, one can suppose that $E_1$ is also in $\mathcal{V}_m$. In fact, set $\alpha_i = g_i(\tau, E_i)$ for $i = 1, 2$. If $\alpha_1 = 0$, then $E_1 \in \mathcal{V}_m$. Suppose $\alpha_1 \neq 0$; then one can check easily that

$$\alpha_1^2 \left( \frac{\alpha_2}{\alpha_1} (U_1 + i E_1) \right),$$

is also a standard basis for $P$.

Then, one can write this standard basis in the form $(z' = U_1' + i E_1', w' = U_2' + i E_2')$, where

$$U_1' = \frac{\alpha_2}{\alpha_1} (U_2 - \frac{\alpha_2}{\alpha_1} U_1) \in \mathcal{V}_m,$$

$$E_1' = \frac{\alpha_2}{\alpha_1} (E_2 - \frac{\alpha_2}{\alpha_1} E_1) \in \mathcal{V}_m,$$

$$U_2' = \frac{\alpha_2}{\alpha_1} (U_1 + \frac{\alpha_2}{\alpha_1} U_2) \in \mathcal{V}_m,$$

as required by the lemma.

This completes the proof of Theorem I. 

The proof of Theorem II is similar. It suffices to remark that in the case when the dimension of $M$ is 4, we must have in the previous proof $E_1 = 0$, that is, $\beta_1 = 0$, since $E_1$ and $\tau$ are at the same moment orthogonal to $U_1, U_2, V_2$. Then $I_{\text{sol}}$ will be positive on $M$ if $F(0)$ is positive, which is nothing but the positivity of the Ricci curvature. This completes the proof of Theorem II.

4. PROOFS OF THE COROLLARIES

Proof of Corollary I. If the manifold admits a Riemannian foliation, then it is locally the total space of a Riemannian submersion. It results then immediately from the previous proofs of Theorems I and II, that such a manifold admits a Riemannian metric with positive isotropic curvature.

Proof of Corollary II. Since the action of the group $G$ on the manifold $M$ is free, the canonical projection $M \to M/G$ is a smooth submersion ($G$ denotes $SU(2)$ or $SO(3)$). Let us equip the fibers with a biinvariant metric of $G$ by using the natural inclusion $G \hookrightarrow T_m M$.

On the other hand, using a $G$-invariant metric on $M$, we define the horizontal distribution and we lift it to a fixed Riemannian metric from $M/G$. Hence the projection $M \to M/G$ is a Riemannian submersion such that its fibers satisfy the condition of Theorem II. Hence, it admits a Riemannian metric with positive isotropic curvature.

Final remarks. 1. Note that the class of manifolds given by Theorems I and II does not admit any metric with positive Ricci curvature since the first Betti number is not zero, in fact the pull-back of the standard form on the circle to such manifolds is a nonzero closed 1-form.

2. We proved in [L3] that the positivity of the $(n - 4)$-curvature is stable under surgeries in codimension $\geq n - 1$ ($n$ is the dimension of the manifold). Since it is close to the positivity of the isotropic curvature, one can think that a similar result
will be true for positive isotropic curvature. Note that this is true in codimension \( n \) since a surgery in codimension \( n \) is a connected sum (this is the result of [MW]). This remark was pointed out to Gromov by Mario Micallef (see [Gr]). But unfortunately an adaptation of our proof in the case of the \( p \)-curvature [L3] to the case of isotropic curvature is possible only when the codimension is \( n \) (and not \( n - 1 \)).
