WEIGHTS IN CODES AND GENUS 2 CURVES

GARY MCGUIRE AND JOSÉ FELIPE VOLOCH

(Communicated by Wen-Ching Winnie Li)

Abstract. We discuss a class of binary cyclic codes and their dual codes. The minimum distance is determined using algebraic geometry and an application of Weil’s theorem. We relate each weight appearing in the dual codes to the number of rational points on a genus 2 curve of 2-rank 1 over a finite field of characteristic 2. The possible values for the number of points on a curve of genus 2 and 2-rank 1 are determined, thus determining the weights in the dual codes.

1. Introduction

Let \( \mathbb{F}_q \) be a finite field with \( q \) elements. In this article, \( q \) will be a power of 2, say \( q = 2^m \), and \( \alpha \) will be a generator for the multiplicative group \( \mathbb{F}_q^* \). Let \( m_i(x) \) denote the minimal polynomial of \( \alpha^i \) over \( \mathbb{F}_2 \). Cyclic codes of length \( n \) are ideals in \( \mathbb{F}_2[x]/(x^n - 1) \). We use the natural basis \( 1, x, x^2, \ldots, x^{n-1} \), and we sometimes identify a polynomial \( c_0 + c_1 x + \cdots + c_{n-1} x^{n-1} \) with the vector \( (c_0, c_1, \ldots, c_{n-1}) \). We label the coordinates by the elements of \( \mathbb{F}_q^* \).

The roots of the generator polynomial of a cyclic code are called the zeros of the code. Determining the exact minimum distance of a cyclic code from its zeros is very difficult in general. In certain cases this can be done, and sometimes also the weights in the dual code can be determined from the zeros alone. Previously-known examples follow, and we present a new example of this phenomenon in this article.

The cyclic code of length \( 2^m - 1 \) generated by \( m_1(x) \) is called the (binary) Hamming code. The cyclic code \( B = B_m \) of length \( 2^m - 1 \) generated by \( m_1(x)m_3(x) \) is called the 2-error-correcting BCH code, and has minimum distance 5 (see section 2). The weights appearing in the dual code \( B_m^\perp \) were determined by Kasami [6]. There are exactly three nonzero weights when \( m \) is odd, and five weights when \( m \) is even. The cyclic code \( M = M_m \) of length \( 2^m - 1 \) generated by \( m_1(x)m_{-1}(x) \) is known as the Melas code. The weights appearing in \( M_m^\perp \) were determined by Lachaud and Wolfmann [7] using results on elliptic curves. In contrast to \( B_m^\perp \), there are many weights in \( M_m^\perp \). Indeed, all even numbers between \( q/2 - \sqrt{q} + 1/2 \) and \( q/2 + \sqrt{q} + 1/2 \) occur. A uniform treatment of these codes was given by Schoof [10]. In his paper Schoof says “It would be very interesting to extend the methods of this paper to other families of cyclic codes. This seems difficult since it involves, in general, curves of genus larger than 1 . . . ”.

In this article we consider the cyclic code \( C = C_m = B_m \cap M_m \), which has length \( 2^m - 1 \) and is generated by \( m_1(x)m_{-1}(x)m_3(x) \). We assume \( m > 2 \) to ensure that the three factors of the generator polynomial of \( C \) are distinct. We will discuss the minimum distance of \( C \) in section 2 using algebraic geometry. In sections 3 and 4 we will determine the weights appearing in the dual code \( C^\perp \), by relating the weights to curves of genus 2, realising the suggestion of Schoof in the above quote. For \( m \) even we have a precise description of all the weights, but not for \( m \) odd. The next step would be to compute the weight distributions of these codes, but this appears to be quite difficult.

In terms of curves, we will determine all the possibilities for the number of points on a curve of genus 2 and 2-rank 1 over a finite field of characteristic 2. This has previously been achieved for elliptic curves \( \mathbb{A} \), and for curves of genus 2 and 2-rank 0 by van der Geer-van der Vlugt \( [5] \). The curves with the extremal values have a split Jacobian.

2. The minimum distance of the codes \( C \)

In this section we investigate the minimum distance of \( C \). We show below that \( B \) has minimum distance 5, and it is not hard to show that \( M \) has minimum distance 5 when \( m \) is odd, and distance 3 when \( m \) is even. Since \( C = B \cap M \), one might hope that \( C \) has distance 7, at least when \( m \) is odd. However, we will show that the minimum distance of \( C \) is 5 for all \( m \geq 16 \).

The computer algebra package \textit{Magma} shows that \( C \) has minimum distance \( d(C) = 7 \) when \( m = 6, 7 \), but that \( d(C) = 5 \) when \( m = 5, 8, 9 \). We presume that \( d(C) = 5 \) when \( 10 \leq m \leq 15 \) but we have not checked this.

As we said, determining the minimum distance of a cyclic code from its zeros is very difficult in general. One result on this problem is known as the BCH bound; see \( [9] \) for example. We use \( wt(c) \) to denote the weight of a codeword \( c(x) \).

**Theorem 1** (BCH bound). Let \( f(x) \) be a codeword in a binary cyclic code of length \( n = 2^m - 1 \). If \( s \) consecutive powers of \( \alpha \) are roots of \( f \), then \( wt(f) \geq s + 1 \).

It follows from the BCH bound that the 2-error-correcting BCH code \( B_m \) has \( d \geq 5 \), since \( \alpha, \alpha^2, \alpha^3, \alpha^4 \) are roots of \( m_1(x)m_3(x) \). Since \( C \subseteq B \), \( d(C) \geq 5 \).

A codeword of even weight in \( C \) has amongst its roots \( \alpha^j \) for \( j = -2, -1, 0, 1, 2, 3, 4 \). By the BCH bound this codeword has weight \( \geq 8 \). Thus there are no codewords of weight 6 in \( C \). We now study codewords of weight 5.

We define the polynomials

\[
f(x, y, z) = x + y + z + x^2 + y^2 + z^2 + x^2y + x^2z + y^2z + z^2x + z^2y
\]

and

\[
g(x, y, z) = x^2y + x^2z + y^2x + y^2z + z^2x + z^2y + xyz + xy + xz + yz + x^2yz + xy^2z + xyz^2
\]

over a field of characteristic 2. Let \( K \) be the algebraic closure of \( \mathbb{F}_2 \). We define an algebraic curve \( X \) by

\[
X = \{(x, y, z) \in K^3 : f(x, y, z) = 0 \text{ and } g(x, y, z) = 0\}
\]

and define \( X_m \) to be the set of points on \( X \) that have coordinates in \( \mathbb{F}_{2^m} \).
Lemma 2. The cyclic code $C$ of length $2^m - 1$ has minimum distance 5 if and only if there are rational points $(x, y, z)$ on $X_m$ with the property that $0, 1, x, y, z, 1 + x + y + z$ are pairwise distinct.

Proof. A parity check matrix for $C$ is

$$
\begin{bmatrix}
1 & \alpha & \alpha^2 & \cdots & \alpha^i & \cdots & \alpha^{2^m-2} \\
1 & \alpha^3 & \alpha^6 & \cdots & \alpha^{3i} & \cdots & \alpha^{3(2^m-2)} \\
1 & \alpha^{-1} & \alpha^{-2} & \cdots & \alpha^{-i} & \cdots & \alpha^{-(2^m-2)}
\end{bmatrix},
$$

and it follows that codewords of weight 5 with a 1 in position 1 are in one-to-one correspondence with field elements $x, y, z, w \in \mathbb{F}_2^m$ such that

1. $1 + x + y + z + w = 0,$
2. $1 + x^3 + y^3 + z^3 + w^3 = 0,$
3. $1 + x^{-1} + y^{-1} + z^{-1} + w^{-1} = 0,$

and $0, 1, x, y, z, w$ are pairwise distinct.

Substituting $1 + x + y + z$ for $w$ in equation (2) gives

$$1 + x^3 + y^3 + z^3 + (1 + x + y + z)^3 = 0$$

or

$$x + y + z + x^2 + y^2 + z^2 + x^2 y + x^2 z + y^2 x + y^2 z + z^2 x + z^2 y = 0$$

which leads to the definition of $f.$

Multiplying (3) by $xyzw$ gives

$$xyzw + yzw + xzw + xyw + xyz = 0$$

and substituting for $w$ now gives

$$(1 + x + y + z)(xyz + yz + xz + xy) + xyz = 0.$$ 

Expanding this out leads to

$$x^2 y + x^2 z + y^2 x + y^2 z + z^2 x + z^2 y + xyz + xy + xz + yz + x^2 yz + xy^2 z + xyz^2 = 0$$

which is where we obtain the definition of $g.$

The proof is complete when we observe that the steps in deriving $f$ and $g$ are reversible; given a point on $X_m$ with $0, 1, x, y, z, 1 + x + y + z$ distinct, one can recover a codeword of weight 5 with a 1 in position 1. Since $C$ is cyclic, any weight 5 codeword has a cyclic shift with a 1 in position 1. □

We will apply Weil’s theorem to $X.$ Normally Weil’s theorem is applied to nonsingular curves, but a straightforward check via the Jacobian matrix shows that $X$ has exactly four singular points. However, the nonsingularity hypothesis in Weil’s theorem can be replaced by absolute irreducibility, and we show next that this indeed holds for our curve $X.$

Lemma 3. The curve $X$ is absolutely irreducible.

Proof. Define

$$a(x, y) = 1 + x + y, \quad c(x, y) = xy + x + y,$$

and

$$h(x, y) = (y^2 + y + 1)x^3 + (y^3 + 1)x^2 + (y^3 + y)x + (y^3 + y^2).$$

With $f$ and $g$ as above, we verify that $ag + cf = h,$ which is independent of $z.$ It is straightforward to check that $h$ is absolutely irreducible. (This can be done by
hand or by using a computer package such as \textit{Magma}. Since \( h \) is of degree 3 in \( x \) it is enough to check irreducibility over \( \mathbb{F}_8 \). \textit{Magma} also shows that \( h = 0 \) has genus 3.)

Let \( Y \) be the plane curve \( h = 0 \). Since \( f = az^2 + a^2z + b \) and \( g = cz^2 + acz + d \) for some polynomials \( b(x, y) \) and \( d(x, y) \), projection on the \( x, y \) plane gives a map from \( X \) to \( Y \), which is of degree 2. Since we already know that \( Y \) is absolutely irreducible, we get that either \( X \) is also absolutely irreducible or it has two components.

Let \( w \) be a primitive 3rd root of 1 in \( GF(4) \). Then \( h(w, w^2) = 0 \) while \( h_x(w, w^2) = w \) and \( h_y(w, w^2) = w^2 \). So the point \( (w, w^2) \) is a smooth point of \( Y \) with tangent \( y = w^2x + w \).

In the equation \( f = 0 \) make the substitution \( v = z/a \), and the equation becomes \( v^2 + v = b/a^3 \).

Consider \( b/a^3 \) as a function on \( Y \), and consider its behaviour near the point \( (w, w^2) \). Note that \( a \) vanishes at \( (w, w^2) \), but since \( a = 0 \) is not the tangent to \( Y \) at \( (w, w^2) \), the function \( a \) has a simple zero at \( (w, w^2) \). On the other hand \( b(w, w^2) = 1 \), so \( b/a^3 \) has a triple pole at \( (w, w^2) \). However, if \( v^2 + v \) has a pole at a point \( P \) then the pole must have even order (the order is \( 2t \), where \( t \) is the order of \( v \) at \( P \)). Thus there cannot be a function \( v \) on \( Y \) with \( v^2 + v = b/a^3 \). This means that the polynomial \( v^2 + v + b/a^3 \) is irreducible over the function field of \( Y \), which entails that \( X \) is absolutely irreducible. \( \square \)

\textbf{Theorem 4.} The cyclic code \( C \) of length \( 2^m - 1 \) has minimum distance 5 for all \( m \geq 16 \).

\textbf{Proof.} By Lemma \( \ref{lemma2} \) we must show that \( X_m \) has points \( (x, y, z) \) with \( 0, 1, x, y, z, 1 + x + y + z \) distinct, for all \( m \) sufficiently large. By Lemma \( \ref{lemma3} \) we know that \( X_m \) is absolutely irreducible. Let \( N_m = |X_m| \). By Weil’s theorem, \( |N_m - (2^m + 1)| \leq 2g\sqrt{2m} + C \), where \( g \) is the genus of (a smooth model of) \( X \) and \( C \) is a constant independent of \( m \) which can be given in terms of the degree of \( X \).

The number of points on \( X_m \) such that \( 0, 1, x, y, z, 1 + x + y + z \) are not distinct is 4. This is straightforward to check using such factorizations as \( f(0, y, z) = (y + 1)(z + 1)(y + z) \), and we omit the details (the four points are \( (0, 0, 0) \), \( (1, 0, 0) \), \( (0, 1, 0) \), and \( (0, 0, 1) \)).

It follows from the previous two paragraphs that there are points on \( X_m \) with \( 0, 1, x, y, z, 1 + x + y + z \) distinct for all \( m \) sufficiently large.

Using a refined version of Weil’s theorem from \( \cite{11} \), we obtain \( |N_m - (2^m + 1)| \leq 220\sqrt{2m} \). It follows from this inequality that \( N_m > 4 \) once \( m \geq 16 \). \( \square \)

It can be easily shown that the genus of \( X \) is between 11 and 13, but we have not computed its exact value.

3. The weights in the dual codes \( C^\perp \), \( m \) even

Let \( q = 2^m \). By Delsarte’s theorem (see \( \cite{10} \) or \( \cite{9} \)),

\[ C^\perp = \{(Tr(a/x + bx + cx^3))_{x \in \mathbb{F}_q^*} : a, b, c \in \mathbb{F}_q\} \]

Knowing the weights in \( C^\perp \) is equivalent to knowing how many 0’s are in a typical codeword. By Hilbert’s Theorem 90, we want to know how many solutions there
are to
\[ y^2 + y = \frac{a}{x} + bx + cx^3 \]
over $\mathbb{F}_{2^m}$. If we denote by $N$ the number of rational points in a complete smooth model of the above curve, then the weight of the vector whose entries are $Tr(a/x + bx + cx^3)$, as we vary $x \in \mathbb{F}_q$, is $q - 1 - (N - 2)/2 = q - N/2$.

Recall that every curve has an abelian variety associated to it called its Jacobian. An abelian variety $A$ over a field of characteristic $p > 0$ is said to have $p$-rank $s$ if the subgroup of points of order $p$ of $A$ (over an algebraically closed field of definition) has cardinality $p^s$. By the two-rank of a curve we mean the two-rank of its Jacobian.

**Lemma 5.** Curves of the form (4) can be characterised as curves defined over $\mathbb{F}_{2^m}$ of genus 2, two-rank 1, whose number of rational points is divisible by 4.

**Proof.** From [2], it follows that a curve of genus 2 and two-rank 1 has an equation $y^2 + y = a/x + bx + cx^3 + d$. Let us now show that we may take $d = 0$ when $N \equiv 0 \pmod{4}$. As the number of points is zero modulo 4, $\sum_{x \in \mathbb{F}_q} Tr(a/x + bx + cx^3 + d) = 0$.

But $\sum_{x \in \mathbb{F}_q} 1/x = \sum_{x \in \mathbb{F}_q} x = \sum_{x \in \mathbb{F}_q} x^3 = 0$ if $q > 4$, so we get $Tr(d) = 0$ and $d = e^2 + e$ for some $e$, and a change of variable $y \mapsto y + e$ puts the equation in the form stated with $d = 0$. Conversely, if $d = 0$, then $N \equiv 0 \pmod{4}$ as $\sum_{x \in \mathbb{F}_q} Tr(a/x + bx + cx^3) = 0$.

An abelian variety is called simple if it is not isogenous to a product of abelian varieties of smaller dimension. Maisner and Nart classified which isogeny classes of $p$-rank one contain Jacobians.

**Theorem 6** (Maisner-Nart, [8]). Let $q = 2^m$. There exists a curve of the form (4) with $N = q + 1 + a_1$ points over $\mathbb{F}_{2^m}$ and simple Jacobian if and only if
\begin{enumerate}
  \item $a_1$ is odd,
  \item $|a_1| \leq 4\sqrt{q}$,
  \item there exists an integer $a_2$ such that
    \begin{enumerate}
      \item $2|a_1|\sqrt{q} - 2q \leq a_2 \leq a_1^2/4 + 2q$,
      \item $a_2$ is divisible by $2^{[m/2]}$,
      \item $\Delta = a_1^2 - 4a_2 + 8q$ is not a square in $\mathbb{Z}$,
      \item $\delta = (a_2 + 2q)^2 - 4qa_1^2$ is not a square in $\mathbb{Z}$.
    \end{enumerate}
\end{enumerate}

This statement combines Lemma 2.1, Theorem 2.9 part (M) and Corollary 2.17 of [8], and our Lemma 5.

**Lemma 7.** Let $q = 2^m$ where $m$ is even. Then each even number in the interval $[q/2 - 2\sqrt{q} + q^{1/4} - 1/2, q/2 + 2\sqrt{q} - q^{1/4} - 1/2]$ occurs as a weight in $C^1$, and these weights arise from curves of type (4) whose Jacobian is simple.

**Proof.** Assume that $m$ is even. If $a_1, a_2$ satisfy the conditions of Theorem 6, then $|a_1| \leq 4\sqrt{q} - 2q^{1/4}$. Indeed, if $a_2 = 2|a_1|\sqrt{q} - 2q$, then $\Delta = (|a_1| + 4\sqrt{q})^2$ is a square, so it is ruled out. Thus $2|a_1|\sqrt{q} - 2q + \sqrt{q} \leq a_2 \leq a_1^2/4 + 2q$, which leads to the stated inequality.

Conversely, if $a_1$ satisfies the inequality $|a_1| \leq 4\sqrt{q} - 2q^{1/4}$, let $a_2 = 2|a_1|\sqrt{q} - 2q + \sqrt{q}$. We must check that $\Delta$ and $\delta$ are not squares in $\mathbb{Z}$ and $\mathbb{Z}$, respectively.

First, substitution gives $\Delta = (4\sqrt{q} - |a_1|)^2 - 4\sqrt{q}$. Suppose $\Delta = t^2$, where $t$ is a positive integer. Then $(4\sqrt{q} - |a_1| - t)(4\sqrt{q} - |a_1| + t) = 4\sqrt{q}$. By unique factorization
in \(\mathbb{Z}\), we conclude that \(4\sqrt{q} - |a_1| - t = 2^k\) and \(4\sqrt{q} - |a_1| + t = 2^\ell\) for some positive integers \(k\) and \(\ell\) with \(k + \ell = 2 + m/2\). Adding gives \(2(4\sqrt{q} - |a_1|) = 2^k + 2^\ell\).

Since \(a_1\) is odd, one of \(k\) and \(\ell\) must be 1. If \(\ell = 1\), then \(4\sqrt{q} - |a_1| + t = 2\), so \(4\sqrt{q} - |a_1| = t = 1\), a contradiction. Suppose now that \(k = 1\) (so \(\ell = 1 + m/2\)). It follows that \(t = 4\sqrt{q} - |a_1| - 2\). Substituting this value for \(t\) into \(4\sqrt{q} - |a_1| + t = 2^\ell\) yields \(|a_1| = 3\sqrt{q} - 1\). Thus, if \(|a_1| \neq 3\sqrt{q} - 1\) we have shown that \(\Delta\) is not a square.

If \(|a_1| = 3\sqrt{q} - 1\), then choose \(a_2 = 2|a_1|\sqrt{q} - 2q + 2\sqrt{q}\). A similar argument as above leads to a contradiction.

Next, substituting for \(a_2\) gives

\[
\delta = (a_2 + 2q)^2 - 4qa_1 = (2|a_1|\sqrt{q} + \sqrt{q})^2 - 4qa_1^2 = q(1 + 4|a_1|).
\]

It is well known (see [11], ch. II, for example) that an element \(2^ru\) (where \(u\) is a unit) of \(\mathbb{Z}_2\) is a square if and only if it has the form \(2^r a\) where \(a\) is odd and \(1 \equiv a \pmod{4}\).

We still need to analyse which weights come from curves whose Jacobian is non-simple. We do this in the proof of Theorem 8. We note that by [8], Corollary 2.17, the field of definition does not matter to determine simplicity.

**Theorem 8.** Let \(q = 2^m\) where \(m\) is even, let \(I = \left\lfloor q/2 - 2\sqrt{q}, q/2 + 2\sqrt{q} - 1\right\rfloor\) and let \(J = \left\lfloor q/2 - 2\sqrt{q} + q^\pm - \frac{1}{2}, q/2 + 2\sqrt{q} - q^\pm - \frac{1}{2}\right\rfloor\). Then all weights in \(C^\perp\) are even integers in \(I\). All even integers in \(J\) do occur as weights, and an even integer in \(I \setminus J\) occurs as a weight if and only if it has the form \(q/2 + (\pm 2\sqrt{q} + a + 1)/2\), where \(a \equiv 3 \pmod{4}\) and \(\pm 2\sqrt{q} - a\) is not squarefree.

**Proof.** We continue the notation from before. The weights are the numbers \(q - N/2\), where \(N = q + 1 + a_1\) ranges over the number of points on curves of type [1]. From Theorem 6 \(a_1\) is odd and \(|a_1| \leq 4\sqrt{q}\). Thus \(-4\sqrt{q} + 1 \leq a_1 \leq 4\sqrt{q} - 1\), and this is equivalent to saying that the weights lie in \(I\). All weights in \(C^\perp\) are even since 1 is a zero of the code. (This entails \(N \equiv 0 \pmod{4}\), which means \(a_1 \equiv 3 \pmod{4}\).)

By Lemma 7 all weights in \(J\) do occur as weights.

We now study curves of type [11] whose Jacobian is not simple. In this case the Jacobian must be isogenous to \(E' \times E\), where \(E'\) is an elliptic curve of two-rank 0 (a supersingular elliptic curve) and \(E\) is an elliptic curve of two-rank 1 (an ordinary elliptic curve). It is known (see [10] for example) that a supersingular elliptic curve \(E'\) has \(q + 1 - a'\) points, where \(a' \in \{0, \pm \sqrt{q}, \pm 2\sqrt{q}\}\) (as \(m\) is even). It is also known by results of Honda and Tate that an ordinary elliptic curve \(E\) exists with \(q + 1 - a\) points whenever \(a\) is odd and \(|a| \leq 2\sqrt{q}\). We will investigate when we can construct a curve of genus 2 having \(N = q + 1 - a' - a\) points over \(\mathbb{F}_q\) whose Jacobian is isogenous to \(E' \times E\). To do this we apply the construction of [11], section 1. There it is proved that such a curve exists if and only if (recall we are assuming that the characteristic is two), for some odd prime \(p\), there is an isomorphism of Galois modules between \(E'/p\) and \(E/p\), reversing the Weil pairing.

We will restrict ourselves to the case that \(E'\) has \(q + 1 + 2\sqrt{q}\) points. In the other cases the construction can be done whenever \(a - a' \neq \pm 1\), but it leads to weights in the interval \(J\), which are therefore not interesting for our purposes. Returning to the case in question, the action of Frobenius on \(E'/p\) is multiplication by a scalar \(k = \pm \sqrt{q}\). We need to have the same be true of \(E/p\), and then any isomorphism of
We need only to consider the values of $\pi - k$ has a kernel $\Gamma$ on $E[p]$ which is also the image of $\pi - k$ on $E[p]$. Thus $\Gamma$ is invariant under $\pi$ and hence $E = E/\Gamma$ is defined over $\mathbb{F}_q$ and is isogenous to $E$. Now $\pi - k = 0$ on $E[p]/\Gamma \subset E[p]$ and by the same argument as above (since the congruence holds modulo $p^2$) $\pi - k = 0$ on a cyclic subgroup of $E[p^2]$ which projects to a different subgroup of $E[p]$, thus $\pi - k = 0$ on $E[p]$. To summarize, we can construct the curve of genus two if $a' \equiv a \pmod{p^2}$ for some prime $p$, when $a' = \pm 2\sqrt{q}$.

Therefore a value of $a_1 = \pm 2\sqrt{q} + a$ is realisable from this construction if and only if $\pm 2\sqrt{q} - a$ is not squarefree. \hfill $\square$

Here are the lists of weights in a few cases:

weights in $I \setminus J$ none none 452 1924

We point out that the weights are not necessarily all the even numbers in an interval, as illustrated by the $q = 2^{12}$ case.

4. The weights in the dual codes $C^\perp$, $m$ odd

Let us now consider the case $m$ odd.

**Theorem 9.** Let $q = 2^m$ where $m$ is odd, let $I = [q/2 - 2\sqrt{q}, q/2 + [2\sqrt{q}] - 1]$ and let $J = [q/2 - 2\sqrt{q} + (8q)^{1/2} - 1, q/2 + 2\sqrt{q} - (8q)^{1/2} - 1]$. Then all weights in $C^\perp$ are even integers in $I$, and all even integers in $J$ do occur as weights.

**Proof.** We need only to consider the values of $a_1$ afforded by Theorem [8] since the curves with split Jacobian will have number of points of the form $q + 1 + a, q + 1 \pm \sqrt{2q} + a$, for some $a$ satisfying $|a| \leq 2\sqrt{q}$ which will lead to weights in $J$. Note also that we can improve the inequality on $a_1$ to $|a_1| \leq 2[2\sqrt{q}]$, as noted in [8]. This leads to interval $I$ and the first statement of the theorem.

Let $q' = 2^{(m+1)/2}$. Let $a_1$ be an odd integer and let $a_2$ be any integer divisible by $q'$, and put $\delta = (a_2 + 2q)^2 - 4qa_1^2$. We will show that $\delta$ is not a square in $\mathbb{Z}_2$. First consider the case where $a_2 = q'u$, $u$ odd. Recall that $(q')^2 = 2q$. Then $\delta/2q \equiv u^2 - 2aq_1^2 \pmod{8}$. As $u^2 = a_1^2 \equiv 1 \pmod{8}$ we get $\delta/2q \equiv 7 \pmod{8}$ and $\delta$ is not a square in $\mathbb{Z}_2$. If $a_2 = 2q'u$ and $a_2$ is odd, then $\delta/4q = 2u^2 - a_1^2$ is odd. Again $\delta$ is not a square in $\mathbb{Z}_2$, as $\delta = 2^r u$ where $r$ is odd and $u$ is a unit. Finally, if $a_2/q' \equiv 0 \pmod{4}$, then $\delta/2q = -2a_1^2 \equiv -2 \pmod{8}$, so $\delta$ is again not a square in $\mathbb{Z}_2$.

We now assume further that $a_1 \in J$, then there exists an integer $a_2$ such that $a_2, a_2 + q'$ satisfy conditions (a) and (b) of Theorem [8]. By the above argument they
also satisfy condition (d). We will show that at least one of them satisfies condition 
(c).
Suppose neither of them satisfies condition (c). Let \( \Delta(b) = a_1^2 - 4b + 8q \). If \( \Delta(a_2) = u^2, \Delta(a_2 + q') = v^2 \) for positive integers \( u, v \), then \( u^2 - v^2 = 4q' \). It 
follows that \( u - v = 2^r, u + v = 2s \) for some integers \( r, s \), where \( r + s = (m + 5)/2 \). 
So \( v = 2^{r-1} - 2^{s-1} \). However, since \( a_1 \) is odd, it follows that \( v^2 = \Delta(a_2 + q') \) is 
also odd, so \( v \) is odd and thus \( r = 1 \) and \( s = (m + 3)/2 \), which implies that 
\( u = q' + 1 \) and so \( a_1^2 \equiv \Delta(a_2) = u^2 \equiv 1 \mod 2q' \). Since \( a_1 \equiv 3 \mod 4 \) it follows 
that \( a_1 \equiv -1 \mod q' \). On the other hand \( |a_1| \leq 4\sqrt{q} = 2\sqrt{2q} \), and we conclude 
that \( a_1 = -1 + nq' \), where \( n \in \{0, \pm 1, \pm 2\} \). We can then conclude that there exists 
a possibly different integer \( a_2 \) such that \( a_2, a_2 + q', a_2 + 2q' \) satisfy conditions (a) 
and (b) of Theorem \( 6 \). By the above argument they also satisfy condition (d). We 
proceed to show that at least one of them also satisfies condition (c). If none of 
them satisfies condition (c), then we can apply the above argument to both pairs 
\( a_2, a_2 + q' \) and \( a_2 + q', a_2 + 2q' \). However, \( u, v \) were uniquely determined in terms of 

\( q' \) above, so we cannot have two such pairs. The theorem now follows from Theorem 
\( 6 \). \( \square \)

Here are the lists of weights in a few cases. Again we note that the weights are 
not necessarily all the even numbers in an interval, as illustrated by the \( q = 2^{11} \) 
case.

<table>
<thead>
<tr>
<th>( q )</th>
<th>( 2^9 )</th>
<th>( 2^{10} )</th>
<th>( 2^{11} )</th>
</tr>
</thead>
<tbody>
<tr>
<td>( I )</td>
<td>42,85</td>
<td>211,300</td>
<td>934,1113</td>
</tr>
<tr>
<td>( J )</td>
<td>47,80</td>
<td>219,292</td>
<td>945,1102</td>
</tr>
<tr>
<td>weights in ( I \setminus J )</td>
<td>46,</td>
<td>216,218</td>
<td>938,942,944</td>
</tr>
<tr>
<td>82,84</td>
<td>294,296</td>
<td>1104,1106</td>
<td></td>
</tr>
</tbody>
</table>

We do not have a precise description of the weights in \( I \setminus J \), unlike the \( m \) even 
case. The entries in the table for \( I \setminus J \) were determined by computer.
