HIGHER ORDER TURÁN INEQUALITIES FOR THE RIEMANN $\xi$-FUNCTION

DIMITAR K. DIMITROV AND FÁBIO R. LUCAS

(Communicated by Walter Van Assche)

Abstract. The simplest necessary conditions for an entire function
\[ \psi(x) = \sum_{k=0}^{\infty} \gamma_k \frac{x^k}{k!} \]
to be in the Laguerre-Pólya class are the Turán inequalities
\[ \gamma_k^2 - \gamma_{k+1} \gamma_{k-1} \geq 0. \]
These are in fact necessary and sufficient conditions for the second degree generalized Jensen polynomials associated with $\psi$ to be hyperbolic. The higher order Turán inequalities
\[ 4(\gamma_n^2 - \gamma_{n-1} \gamma_{n+1})(\gamma_{n+1}^2 - \gamma_n \gamma_{n+2}) - (\gamma_n \gamma_{n+1} - \gamma_{n-1} \gamma_{n+2})^2 \geq 0 \]
are also necessary conditions for a function of the above form to belong to the Laguerre-Pólya class. In fact, these two sets of inequalities guarantee that the third degree generalized Jensen polynomials are hyperbolic.

Pólya conjectured in 1927 and Csordas, Norfolk and Varga proved in 1986 that the Turán inequalities hold for the coefficients of the Riemann $\xi$-function. In this short paper, we prove that the higher order Turán inequalities also hold for the $\xi$-function, establishing the hyperbolicity of the associated generalized Jensen polynomials of degree three.

1. Introduction

The real entire function $\psi(x)$ is said to belong to the Laguerre-Pólya class $\mathcal{LP}$ if it can be represented as
\[ \psi(x) = cx^m e^{-\alpha x^2 + \beta x} \prod_{k=1}^{\infty} (1 + x/x_k) e^{-x/x_k}, \]
where $c, \beta, x_k$ are real, $\alpha \geq 0$, $m$ is a nonnegative integer and $\sum x_k^{-2} < \infty$. Similarly, the real entire function $\psi_1(x)$ is a function of type I in the Laguerre-Pólya class, written $\psi_1 \in \mathcal{LP}_I$, if $\psi_1(x)$ or $\psi_1(-x)$ can be represented in the form
\[ \psi_1(x) = cx^m e^{\sigma x} \prod_{k=1}^{\infty} (1 + x/x_k), \]
where \( c \) and \( \sigma \) are real, \( \sigma \geq 0 \), \( m \) a nonnegative integer, \( x_k > 0 \), and \( \sum 1/x_k < \infty \). The real polynomials with only real zeros are called \emph{hyperbolic} ones. It is clear that \( \mathcal{L}^I \subset \mathcal{L}^P \). The functions in \( \mathcal{L}^P \), and only these, are uniform limits, on compact subsets of \( \mathbb{C} \), of hyperbolic polynomials (see, for example, Levin [8, Chapter 8]). Similarly, \( \psi \in \mathcal{L}^I \) if and only if it is a uniform limit on the compact sets of the complex plane of hyperbolic polynomials whose zeros are either all positive, or all negative. Thus, the classes \( \mathcal{L}^P \) and \( \mathcal{L}^I \) are closed under differentiation, that is, if \( \psi \in \mathcal{L}^P \), then \( \psi^{(\nu)} \in \mathcal{L}^P \) for every \( \nu \in \mathbb{N} \) and similarly, if \( \psi \in \mathcal{L}^I \), then \( \psi^{(\nu)} \in \mathcal{L}^I \). Pólya and Schur [13] proved that if

\[
\psi(x) = \sum_{k=0}^{\infty} \frac{\gamma_k x^k}{k!}
\]

belongs to \( \mathcal{L}^P \) and its Maclaurin coefficients \( \gamma_k = \psi^{(k)}(0) \) are all nonnegative, then \( \psi \in \mathcal{L}^I \). It is worth mentioning that the sequences \( \{\gamma_k\} \) of Maclaurin coefficients of \( \mathcal{L}^I \)-functions are called \emph{multiplier sequences}, and these are the sequences with the property that, for any \( n \in \mathbb{N} \) and every hyperbolic polynomial \( \sum_{k=0}^{n} a_k x^k \), the polynomial \( \sum_{k=0}^{n} a_k \gamma_k x^k \) is also a hyperbolic one.

The main reason for the interest in the Laguerre-Pólya class is the fact that it is closely related to the celebrated Riemann hypothesis. Recall that the Riemann \( \xi \)-function is defined by

\[
\xi(iz) = \frac{1}{2} (z^2 - 1/4) \pi^{-z/2} e^{-z/4} \Gamma(z/2 + 1/4) \zeta(z + 1/2),
\]

where \( \zeta(z) \) is the Riemann \( \zeta \)-function and \( \Gamma(z) \) is the gamma function. It is known that \( \xi(z) \) is an entire function of order one. Moreover, it can be represented in the form

\[
\xi(x/2) = 8 \int_0^\infty \Phi(t) \cos xtdt,
\]

where

\[
\Phi(t) = \sum_{n=1}^{\infty} (2n^4 \pi^2 e^{9t} - 3n^2 \pi e^{5t}) \exp(-n^2 \pi e^{4t}).
\]

Then

\[
\frac{1}{8} \xi(x/2) = \sum_{k=0}^{\infty} (-1)^k \tilde{b}_k \frac{x^{2k}}{(2k)!} \quad \text{with} \quad \tilde{b}_k = \int_0^\infty t^{2k} \Phi(t) dt, \quad k = 0, 1, \ldots.
\]

On setting \( z = -x^2 \), we obtain the entire function

\[
\xi_1(z) = \sum_{k=0}^{\infty} \tilde{b}_k \frac{z^k}{(2k)!} = \sum_{k=0}^{\infty} \gamma_k \frac{z^k}{k!}, \quad \hat{\gamma}_k = \frac{k! \tilde{b}_k}{(2k)!}
\]

of order \( 1/2 \). Thus, the Riemann hypothesis is equivalent to the statement that the entire function \( \xi(z) \) belongs to \( \mathcal{L}^P \), or equivalently, that \( \xi_1(z) \in \mathcal{L}^I \). Consequently, any new necessary or sufficient conditions on a function \( \psi \in \mathcal{L}^P \) are of significant interest.

The simplest necessary condition for a function (2) to be in \( \mathcal{L}^P \) is that the so-called Turán inequalities

\[
T_k := \gamma_k^2 - \gamma_{k-1} \gamma_{k+1} \geq 0, \quad k \in \mathbb{N},
\]

\[
(3)
\]
Lemma 1. Let \( \text{conditions that these hold are that the corresponding Turán determinants with nonzero leading coefficient } \)

\[
\begin{align*}
g_{n,k}(x) &= g_{n,k}(\psi; x) := \sum_{j=0}^{n} \binom{n}{j} \gamma_{k+j} x^j, \quad n, k = 0, 1, \ldots
\end{align*}
\]

It is known (see [8, 10]) that \( g_{n,k}(\psi; x) \) hyperbolic. Then the Jensen polynomials are hyperbolic in order that the generalized third degree Jensen polynomials \( g_{2,k}(x) \) must be hyperbolic immediately yields Turán’s inequalities [3]. An extension of [3] was obtained in [4] where the inequalities

\[
(5) \quad H_k := 4(\gamma_k^2 - \gamma_{k-1} \gamma_{k+1})(\gamma_{k+1}^2 - \gamma_k \gamma_{k+2}) - (\gamma_k \gamma_{k+1} - \gamma_{k-1} \gamma_{k+2})^2 \geq 0, \quad k \in \mathbb{N},
\]

were shown to be another necessary condition that the entire function \( \psi(x) \), defined by (5), is in \( \mathcal{L} \mathcal{P} \). We call the new set of inequalities higher order Turán inequalities. The idea of the proof is rather simple and is based on the fact that (5) are necessary conditions in order that the generalized third degree Jensen polynomials \( g_{3,k-1}(x) \) are hyperbolic. In fact, it is not difficult to prove that (3) and (5) are also sufficient for \( g_{3,k-1}(x) \) to be hyperbolic:

Lemma 1. Let \( k \in \mathbb{N} \). Then the real polynomial

\[
g_{3,k-1}(x) = \gamma_{k-1} + 3 \gamma_k x + 3 \gamma_{k+1} x^2 + \gamma_{k+2} x^3
\]

with nonzero leading coefficient \( \gamma_{k+2} \) is hyperbolic if and only if the inequalities

\[
\gamma_{k+1}^2 - \gamma_k \gamma_{k+2} \geq 0
\]

and

\[
4(\gamma_k^2 - \gamma_{k-1} \gamma_{k+1})(\gamma_{k+1}^2 - \gamma_k \gamma_{k+2}) - (\gamma_k \gamma_{k+1} - \gamma_{k-1} \gamma_{k+2})^2 \geq 0
\]

hold simultaneously.

Let us consider entire functions which are represented by Fourier transforms of even, positive and sufficiently fast decaying kernels \( K(t) \),

\[
F(x) = \frac{1}{2} \int_{-\infty}^{\infty} K(t) e^{ixt} dt = \int_{0}^{\infty} K(t) \cos(xt) dt.
\]

Then

\[
F(z) = \sum_{m=0}^{\infty} \frac{(-1)^m b_m z^{2m}}{(2m)!}, \quad \text{with } b_m := \int_{0}^{\infty} t^{2m} K(t) dt, \quad m = 0, 1, 2, \ldots.
\]

Again, the change of variable, \( z^2 = -x \), gives

\[
F_1(x) := \sum_{k=0}^{\infty} \gamma_k \frac{x^k}{k!} = \sum_{k=0}^{\infty} b_k \frac{x^k}{(2k)!}, \quad \gamma_k := \frac{k!}{(2k)!} b_k.
\]

Then, obviously, \( F \in \mathcal{L} \mathcal{P} \) if and only if \( F_1 \in \mathcal{L} \mathcal{P} I \). Then the first necessary conditions that these hold are that the corresponding Turán determinants \( T_k := \gamma_k^2 - \gamma_{k-1} \gamma_{k+1} \) are nonnegative for all \( k \in \mathbb{N} \). Since, obviously,

\[
T_k = c_k \begin{vmatrix} b_k & (2k-1) b_{k-1} \\ b_{k+1} & (2k+1) b_k \end{vmatrix},
\]
where \( c_k := 2^k k!(k+1)!/(2k)!(2k+2)! \), then the Turán inequalities are equivalent to
\[
\tilde{T}_k = (2k+1)b_k^2 - (2k-1)b_{k-1}b_{k+1} \geq 0, \quad k \in \mathbb{N}.
\]
Therefore, the simplest necessary conditions for the Riemann hypothesis are that the inequalities
\[
(2k+1)b_k^2 - (2k-1)b_{k-1}b_{k+1} \geq 0, \quad k \in \mathbb{N},
\]
hold for the moments of the kernel \( \Phi(t) \). In 1927, Pólya [12] conjectured that the inequalities (7) are valid. Pólya’s conjecture was proved in 1986 by Csordas, Norfolk and Varga [2]. In addition to the proof, [2] provides some history concerning the previous attempts involving contributions of Hayman [7] and Grosswald [5, 6]. The key idea of the proof in [2] is to first establish the following sufficient condition:

**Theorem A.** If \( K(t) \) is a positive, even, sufficiently smooth and fast decaying kernel, and \( \log K(\sqrt{t}) \) is concave for \( t > 0 \), that is,
\[
(\log K(\sqrt{t}))'' < 0 \quad \text{for} \quad t > 0,
\]
then the inequalities (6) hold.

Then Csordas, Norfolk and Varga proved by lengthy, careful and detailed analysis of the kernel \( \Phi(t) \) that:

**Theorem B.** The function \( \log \Phi(\sqrt{t}) \) is concave for \( t > 0 \).

It is worth mentioning that the inequality (8) is equivalent to
\[
\frac{d}{dt} \left\{ \frac{K(t)}{tK(t)} \right\} < 0 \quad \text{for} \quad t > 0.
\]
We refer to [1] for an alternative proof of Theorem A as well as for sufficient conditions on a kernel so that its Fourier transform satisfies the so-called double Turán inequalities.

Preliminaries and history aside, we turn to higher order Turán inequalities for Fourier transforms. First of all, simple calculations show that \( H_k = d_k \hat{H}_k \), where
\[
d_k = \frac{[k]!(k+1)!!^2}{(2k)!(2k+1)!(2k+3)!!^2}
\]
and
\[
\hat{H}_k = 4(2k+3) [(2k+1)b_k^2 - (2k-1)b_{k-1}b_{k+1}][(2k+3)b_k^2 - (2k+1)b_{k-1}b_{k+1} - (2k+1)b_k b_{k+2}]
\]
\[
-(2k+1) [(2k+3)b_k b_{k+1} - (2k-1)b_{k-1}b_{k+2}]^2.
\]

We consider kernels which possess certain properties:

**Definition 1.** A function \( K : \mathbb{R} \rightarrow \mathbb{R} \) is called an **admissible kernel** if it satisfies the following properties:

(i) \( K(t) > 0 \) for \( t \in \mathbb{R} \),
(ii) \( K(t) \) is analytic in the strip \( |\text{Im} \ z| < \tau \) for some \( \tau > 0 \),
(iii) \( K(t) = K(-t) \) for \( t \in \mathbb{R} \),
(iv) \( K'(t) < 0 \) for \( t > 0 \), and
(v) for some \( \varepsilon > 0 \) and \( n = 0, 1, 2, \ldots \),
\[
K^{(n)}(t) = \mathcal{O} \left( \exp \left( -|t|^{2+\varepsilon} \right) \right) \quad \text{as} \quad t \rightarrow \infty.
\]
It is well known that the kernel $\Phi(t)$ satisfies these properties.

**Theorem 1.** If $K(t)$ is an admissible kernel with moments $b_k = \int_{-\infty}^{\infty} t^{2k} K(t) dt$ and

$$(\log K(\sqrt{t}))'' < 0 \quad \text{for} \quad t > 0,$$

then $\tilde{H}_k \geq 0$ for every $k \in \mathbb{N}$.

It is quite interesting that the logarithmic concavity of $K(\sqrt{t})$ guarantees not only that the Turán inequalities but also the higher ones hold. Then it follows immediately from Lemma 1, Theorem B and Theorem 1 that

**Corollary 1.** All third degree Jensen polynomials

$$g_{3,k-1}(x) = \hat{\gamma}_{k-1} + 3\hat{\gamma}_k x + 3\hat{\gamma}_{k+1} x^2 + \hat{\gamma}_{k+2} x^3, \quad k \in \mathbb{N},$$

associated with the Riemann $\xi$-function, are hyperbolic.

2. **Proof of the main result**

First we recall some facts concerning the relation between a function in the Laguerre-Pólya class and its Jensen polynomials.

Consider the real entire function $\psi(x)$ defined by (2). Its Jensen polynomials are

$$g_n(x) = g_n(\psi; x) := \sum_{j=0}^{n} \binom{n}{j} \gamma_j x^j, \quad n = 0, 1, \ldots.$$

Jensen himself proved that $\psi \in \mathcal{LP}$ if and only if the corresponding Jensen polynomials $g_n(\psi; x)$ are hyperbolic and that the sequence $\{g_n(\psi; x/n)\}$ converges locally uniformly to $\psi(x)$. Observe that, for any fixed $k \in \mathbb{N}$, the generalized Jensen polynomials $g_{n,k}(\psi; x)$, $k = 0, 1, \ldots$, defined by (4), are the Jensen polynomials associated with $\psi^k(x)$, that is,

$$g_{n,k}(\psi; x) = g_n(\psi^k; x).$$

It is easy to check that the identities

$$g_n^{(\nu)}(x) = (n!/(n - \nu)!) \ g_{n-\nu,0}(x)$$

and

$$(10) \quad g_{n,k}^{(\nu)}(x) = (n!/(n - \nu)!) \ g_{n-\nu,k+\nu}(x)$$

hold. Hence, if $\psi \in \mathcal{LP}$, then all generalized Jensen polynomials (4) are hyperbolic, and by (10), we conclude that $\mathcal{LP}$ is indeed closed under differentiation.

Lemma 1 is a rather straightforward consequence of a classical result of Hermite. Let

$$f(x) = x^n + a_{n-1}x^{n-1} + \cdots + a_0$$

be a real algebraic polynomial. Let $\alpha_1, \alpha_2, \ldots, \alpha_n$ be its zeros and denote by $S_0 = n$ and

$$S_m = \alpha_1^m + \alpha_2^m + \cdots + \alpha_n^m, \quad m = 1, 2, 3, \ldots$$
Theorem D. Let the functions \( \Delta_1, \Delta_2 = \left| \begin{array}{cc} S_0 & S_1 \\ S_1 & S_2 \\ \vdots & \vdots \\ S_{n-1} & S_n \end{array} \right| \) be the determinants of integrals, which will be the main tool in the proof of Theorem 1.

Then Hermite’s theorem [10] states:

**Theorem C.** The polynomial \( f(x) \) is hyperbolic if and only if the minors \( \Delta_k, k = 1, \ldots, n \) are nonnegative. Moreover, the number of distinct zeros of the polynomial \( f(x) \) is equal to the index \( k \) of the last nonzero minor \( \Delta_k \) in the above sequence.

It follows from the proof of Hermite’s theorem that if \( \Delta_{k+1} = 0 \), then \( \Delta_{k+2} = \cdots = \Delta_n = 0 \).

**Proof of Lemma 1.** The fact that the inequalities (3) are necessary conditions for the polynomial \( g_{3,k-1}(x) \) to be hyperbolic follows from a result of Mařík [9]. Let us apply Hermite’s theorem to \( g_{3,k-1}(x) = \gamma_{k-1} + 3\gamma_k x + 3\gamma_{k+1} x^2 + \gamma_{k+2} x^3 \).

Since \( S_0 = 3 \),

\[
S_1 = -\frac{3\gamma_{k+1}}{\gamma_{k+2}}, \quad S_2 = \frac{9\gamma_{k+1}^2}{\gamma_{k+2}^2} - \frac{6\gamma_k}{\gamma_{k+2}}, \quad S_3 = -\frac{27\gamma_{k+1}^3}{\gamma_{k+2}^3} + \frac{27\gamma_{k+1}\gamma_k}{\gamma_{k+2}^2} - \frac{3\gamma_{k-1}}{\gamma_{k+2}},
\]

and

\[
S_4 = \frac{81\gamma_{k+1}^4}{\gamma_{k+2}^4} - \frac{108\gamma_{k+1}^2\gamma_k}{\gamma_{k+2}^3} + \frac{18\gamma_k^2}{\gamma_{k+2}^2} + \frac{12\gamma_{k+1}\gamma_{k-1}}{\gamma_{k+2}}.
\]

Then straightforward calculations show that \( \Delta_2 = 18(\gamma_{k+1}^2 - \gamma_k \gamma_{k+2})/\gamma_{k+2}^2 \) and \( \Delta_3 = 27 \gamma_k \gamma_{k+2}^2/\gamma_{k+2}^3 \), where \( \gamma_k \) is defined by (3). The statement of Lemma 1 then follows immediately from Hermite’s theorem.

Next we recall the following nice formula (cf. [13] Part II, Problem 68), involving determinants of integrals, which will be the main tool in the proof of Theorem 1.

**Theorem D.** Let the functions \( f_1, f_2, g_1, g_2 \) be square integrable in \([0, \infty)\). Then

\[
\left| \int_0^\infty f_1(t)g_1(t)dt \right|^2 \int_0^\infty f_2(t)g_2(t)dt = \frac{1}{2} \int_0^\infty \int_0^\infty f_1(x_1) f_1(x_2) \left| \frac{g_1(x_1) g_1(x_2)}{x_1 K(x_1)} \right| \frac{K'(x_2)}{x_2 K(x_2)} dx_1 dx_2.
\]

**Proof of Theorem 1.** Let \( K(t) \) be an admissible kernel. We define

\[
A(x_1, x_2) = (x_1 + x_2) K(x_1) K(x_2) \left\{ (x_2 - x_1) \left| \frac{K'(x_1)}{x_1 K(x_1)} \right| \frac{K'(x_2)}{x_2 K(x_2)} \right\},
\]

and, for any pair of nonnegative integers \( m \) and \( n \),

\[
I_{m,n} = \int_0^\infty \int_0^\infty x_1^m x_2^n A(x_1, x_2) \, dx_1 dx_2.
\]

The Mean Value Theorem and (3) imply that \( A(x_1, x_2) > 0 \) for every \((x_1, x_2)\) with \( x_1, x_2 > 0, x_1 \neq x_2 \). Recall that

\[
\overline{T}_k = (2k + 1)b_k^2 - (2k - 1)b_{k-1} b_{k+1}.
\]
It was proved in [1] that $2\tilde{T}_k = I_{2k,2k}$. In a similar way, we obtain an explicit expression for the quantity $\tilde{U}_k = (2k + 3)b_kb_{k+1} - (2k - 1)b_{k-1}b_{k+2}$. Since

$$\tilde{U}_k = \left| \begin{array}{c} b_k \\
(2k - 1)b_{k-1} \\
b_{k+2} \\
(2k + 3)b_{k+1} \end{array} \right|$$

and integration by parts yields $(2k - 1)b_{k-1} = -\int_0^\infty t^{2k-1}K'(t)dt$, we have

$$\tilde{U}_k = \left| \begin{array}{c} \int_0^\infty t^{2k}K(t)dt \\
\int_0^\infty t^{2k+4}K(t)dt \end{array} \right|.$$

Applying Theorem D with $f_1(t) = t^{2k}$, $f_2(t) = t^{2k+4}$, $g_1(t) = K(t)$, and $g_2(t) = -K'(t)/t$, we obtain

$$\tilde{U}_k = \frac{1}{2}[I_{2k+2,2k} + I_{2k,2k+2}].$$

Consider the difference $I_{2k+2,2k} - I_{2k,2k+2}$. It follows from the definition of the integrals $I_{m,n}$ that

$$I_{2k+2,2k} - I_{2k,2k+2} = \int_0^\infty \int_0^\infty x_1^{2k}x_2^{2k}(x_1^2 - x_2^2)A(x_1, x_2)dx_1dx_2.$$ 

Denote the last integrand by $G(x_1, x_2)$. Since it is obviously antisymmetric with respect to the line $x_1 = x_2$, that is $G(x_1, x_2) = -G(x_2, x_1)$, then the above integral vanishes and $I_{2k+2,2k} = I_{2k,2k+2}$. This yields

$$\tilde{U}_k = I_{2k+2,2k} = I_{2k,2k+2}.$$ 

Then, by [1],

$$\tilde{H}_k = 4(2k + 3)\tilde{T}_k \tilde{T}_{k+1} - (2k + 1) \tilde{U}_k^2 = (2k + 3)I_{2k,2k}I_{2k+2,2k+2} - (2k + 1) I_{2k+2,2k}I_{2k,2k+2}.$$ 

Consider the difference $\tilde{J}_k := I_{2k,2k}I_{2k+2,2k+2} - I_{2k+2,2k}I_{2k,2k+2}$ and represent it in a form of a determinant:

$$\tilde{J}_k = \left| \begin{array}{c} \int_0^\infty u^{2k}\left[ \int_0^\infty v^{2k}A(u,v)dv \right]du \\
\int_0^\infty u^{2k+2}\left[ \int_0^\infty v^{2k+2}A(u,v)dv \right]du \end{array} \right|.$$ 

Applying Theorem D with $f_1(u) = u^{2k}$, $f_2(u) = u^{2k+2}$, $g_1(u) = \int_0^\infty v^{2k}A(u,v)dv$, and $g_2(u) = \int_0^\infty v^{2k+2}A(u,v)dv$, we obtain

$$\tilde{J}_k = \frac{1}{2} \int_0^\infty \int_0^\infty \left| \begin{array}{c} y_1^{2k} \\
y_1^{2k+2} \\
y_2^{2k+2} \\
y_2^{2k+2} \end{array} \right| g_1(y_1)g_2(y_1) g_1(y_2)g_2(y_2) dy_1dy_2,$$

which is equivalent to

$$\tilde{J}_k = \int_0^\infty \int_0^\infty \left( y_2 - y_1 \right) \Psi'(y) \left( \begin{array}{c} 1 \\
g_1(y_1) \\
g_2(y_2) \end{array} \right) \left( \begin{array}{c} 1 \\
g_1(y_1) \\
g_2(y_2) \end{array} \right) dy_1dy_2.$$ 

Since, by the Mean Value Theorem, the expression in the curly brackets is equal to

$$(y_2 - y_1)^2\Psi'(y)$$

with $\Psi(y) = \frac{g_2(y)}{g_1(y)}$ and $y \in (y_1, y_2)$,

then $\tilde{J}_k \geq 0$ provided that $\Psi'(y) \geq 0$ for every $y \in [0, \infty)$. 

\[\ \]
It remains only to analyze
\[ (g_1(y))^2 \Psi'(y) = (g_1(y))^2 \left( \frac{g_2(y)}{g_1(y)} \right)' = g_2'(y)g_1(y) - g_2(y)g_1'(y). \]

In what follows we shall denote the partial derivatives $\partial^{i+j} F/\partial x^i \partial y^j$ of the bivariate function $F(x, y)$ by $D_{i,j} F(x, y)$ or $F_{i,j}(x, y)$.

Since $g_1(u) = \int_0^\infty v^{2k} A(u, v) dv$ and $g_2(u) = \int_0^\infty v^{2k+2} A(u, v) dv$, these integrals are uniformly convergent with respect to $y$ in $(0, \infty)$, as are the integrals $\int_0^\infty v^{2k} A_{1,0}(y, v) dv$ and $\int_0^\infty v^{2k+2} A_{1,0}(y, v) dv$; thus
\[ g_1'(y) = \int_0^\infty v^{2k} A_{1,0}(y, v) dv \quad \text{and} \quad g_2'(y) = \int_0^\infty v^{2k+2} A_{1,0}(y, v) dv. \]

Hence, the right-hand side of (13) equals
\[ \int_0^\infty v^{2k+2} A_{1,0}(y, v) dv \int_0^\infty v^{2k} A(y, v) dv - \int_0^\infty v^{2k+2} A(y, v) dv \int_0^\infty v^{2k} A_{1,0}(y, v) dv, \]
which we write as a determinant:
\[ (g_1(y))^2 \Psi'(y) = \begin{vmatrix} \int_0^\infty v^{2k} A(y, v) dv & \int_0^\infty v^{2k} A_{1,0}(y, v) dv \\ \int_0^\infty v^{2k+2} A(y, v) dv & \int_0^\infty v^{2k+2} A_{1,0}(y, v) dv \end{vmatrix}. \]

Now, we apply Theorem D for the last time, with $f_1(v) = v^{2k}$, $f_2(v) = v^{2k+2}$, $g_1(v) = A(y, v)$ and $g_2(v) = A_{1,0}(y, v)$, to obtain
\[ 2(g_1(y))^2 \Psi'(y) = \int_0^\infty \int_0^\infty \left\| \begin{array}{cc} z_{1}^{2k} & z_{2}^{2k+2} \\ z_{1}^{2k+2} & z_{2}^{2k+2} \end{array} \right\| A(y, z_1) A_1(y, z_2) A(y, z_1) A_{1,0}(y, z_2) d z_1 d z_2, \]
and the right-hand side is equal to
\[ \int_0^\infty \int_0^\infty \left\{ z_2 - z_1 \right\} \left( z_2 - z_1 \right) \left( z_2 - z_1 \right) \left( z_2 - z_1 \right) d z_1 d z_2. \]

Again the Mean Value Theorem implies that, for any $z_1, z_2$, there exists $z$ in the interval surrounded by $z_1$ and $z_2$, such that the expression in the last curly brackets is equal to
\[ (z_2 - z_1)^2 D_{0.1} \left[ \frac{A_{1,0}(y, z)}{A(y, z)} \right]. \]

Summarizing, we see that $\Psi'(y) > 0$ if
\[ D_{0.1} \left[ \frac{A_{1,0}(y, z)}{A(y, z)} \right] > 0 \quad \text{for} \quad y, z \in (0, \infty). \]

It remains only to analyze
\[ D_{0.1} \left[ \frac{A_{1,0}(y, z)}{A(y, z)} \right] = \frac{A(y, z) A_{11}(y, z) - A_{1,0}(y, z) A_{0,1}(y, z)}{(A(y, z))^2}. \]
Observe that, if we set
\[
B(y, z) := \left| K'(y) \frac{y}{K(y)} K'(z) \frac{z}{K(z)} \right|,
\]
then
\[
A(y, z) = (z^2 - y^2) B(y, z),
A_{1,0} = (z^2 - y^2) B_{1,0} - 2yB,
A_{0,1} = (z^2 - y^2) B_{0,1} + 2zB,
\]
and
\[
A_{1,1} = (z^2 - y^2) B_{1,1} + 2z B_{1,0} - 2y B_{0,1}.
\]
Substituting these expressions into the numerator on the right-hand side of (14), we obtain
\[
A A_{1,1} - A_{1,0} A_{0,1} = (y^2 - z^2)^2 (B B_{1,1} - B_{1,0} B_{0,1}) + 4yz B^2.
\]
The latter function is positive for \(y, z \in (0, \infty)\) provided that \(L = B B_{1,1} - B_{1,0} B_{0,1}\) is positive. A straightforward calculation immediately yields
\[
y^2 z^2 L = \left[ y(K'(y))^2 + K(y)(K'(y) - y K''(y)) \right] \left[ z(K'(z))^2 + K(z)(K'(z) - z K''(z)) \right].
\]
Since
\[
t(K'(t))^2 + K(t)(K'(t) - t K''(t)) = -(t K(t))^2 \left[ K'(t) \frac{t}{t K(t)} \right]'
\]
then
\[
L = K^2(y) \left[ \frac{K'(y)}{y K(y)} \right]' K^2(z) \left[ \frac{K'(z)}{z K(z)} \right]'.
\]
On the other hand,
\[
\left[ \frac{K'(t)}{t K(t)} \right]' < 0 \text{ for all } t > 0,
\]
which implies \(L > 0\). Thus,
\[
\tilde{J}_k = I_{2k, 2k} I_{2k+2, 2k+2} - [I_{2k+2, 2k}]^2 > 0.
\]
Then obviously
\[
(2k + 3)I_{2k, 2k} I_{2k+2, 2k+2} - (2k + 1)[I_{2k+2, 2k}]^2 > 0,
\]
which is equivalent to \(\tilde{H}_k > 0\). This completes the proof of the theorem.

It is worth noting that we have proven that the logarithmic concavity of the kernel \(K(\sqrt{t})\) on the positive real axes implies the stronger inequalities \(\tilde{H}_k > 8 T_k T_{k+1}\).

It is also of interest to point out that there are kernels which satisfy the requirement \((\log K(\sqrt{t}))'' < 0, \ t > 0\), whose cosine transforms \(\int_0^\infty K(t) \cos zt dt\) do not belong to the Laguerre-Pólya class. A simple example is given by \(K(t) = \exp(-t^3)\).

\[\Box\]
