LOG CANONICAL THRESHOLDS
OF QUASI-ORDINARY HYPERSURFACE SINGULARITIES

NERO BUDUR, PEDRO D. GONZÁLEZ-PÉREZ, AND MANUEL GONZÁLEZ VILLA

(Communicated by Lev Borisov)

Abstract. The log canonical thresholds of irreducible quasi-ordinary hypersurface singularities are computed using an explicit list of pole candidates for the motivic zeta function found by the last two authors.

1. Let $f \in \mathbb{C}[x_1,\ldots,x_{d+1}]$ be a non-zero polynomial vanishing at the origin in $\mathbb{C}^{d+1}$. Denote by $Z$ the zero locus of $f$ in a small open neighborhood $U$ of the origin. Consider a log resolution $\mu : Y \to U$ of $Z$ that is an isomorphism above the complement of $Z$, and let $E_i$ for $i \in J$ be the irreducible components of $\mu^{-1}(Z)$. Denote by $a_i$ the order of vanishing of $f \circ \mu$ along $E_i$, and by $k_i$ the order of vanishing of the determinant of the Jacobian of $\mu$ along $E_i$.

The log canonical threshold of $f$ at the origin is defined as

$$\text{lct}_0(f) := \min \left\{ \frac{k_i + 1}{a_i} \mid i \in J \right\}.$$ 

This is independent of the choice of log resolution. A polynomial $f$ is log canonical at $0$ if $\text{lct}_0(f) = 1$. The definition of the log canonical threshold extends similarly to the case of a germ of a complex analytic function $f : (\mathbb{C}^{d+1},0) \to (\mathbb{C},0)$.

The log canonical threshold is an interesting local invariant of the singularities of $Z$ (the smaller the log canonical threshold is, the worse the singularities of $Z$ are) with connections with many other concepts; see [5, 15, 17]. For example, the log canonical threshold of $f$ is the smallest number $c > 0$ such that $|f|^{-2c}$ is not locally integrable. It is also the smallest jumping number of $f$, the negative of the biggest root of the Bernstein-Sato polynomial of $f$, and in certain cases it is a spectral number of $f$. The log canonical threshold can be computed in terms of jet spaces of $\mathbb{C}^{d+1}$ and $Z$, [19]. Furthermore, the set of log canonical thresholds when $d$ is fixed but $f$ varies is known to satisfy the ascending chain condition, [6].

In this paper we give a formula for the log canonical threshold of an irreducible quasi-ordinary polynomial in terms of the associated characteristic exponents; see Theorem 3.1. This result generalizes the well-known case of plane curve singularities; see Example 3.4. Unlike the curve case, the log canonical threshold of a quasi-ordinary hypersurface can involve the second characteristic exponent, not only the first one.

A germ $(Z, 0)$ of an equidimensional complex analytic variety of dimension $d$ is quasi-ordinary (q.o.) if there exists a finite projection $\pi : (Z, 0) \to (C^d, 0)$ that is a local isomorphism outside a normal crossing divisor. If $(Z, 0)$ is a q.o. hypersurface, there is an embedding $(Z, 0) \subset (C^{d+1}, 0)$ defined by an equation $f = 0$, where $f \in C\{x_1, \ldots, x_d\}[y]$ is a q.o. polynomial, that is, a Weierstrass polynomial in $y$ with discriminant $\Delta_y f$ of the form $\Delta_y f = x^\delta u$, for a unit $u$ in the ring $C\{x\}$ of convergent power series in the variables $x = (x_1, \ldots, x_d)$ and $\delta \in Z_{d \geq 0}$. In these coordinates the projection $\pi$ is the restriction of the projection

$$C^{d+1} \to C^d, \quad (x_1, \ldots, x_d, y) \mapsto (x_1, \ldots, x_d).$$

The Jung-Abhyankar theorem guarantees that the roots of a q.o. polynomial $f$ are called q.o. branches, are fractional power series in the ring $C\{x^{1/m}\}$, for some integer $m \geq 1$; see [1]. Denoting by $K$ the field of fractions of $C\{x_1, \ldots, x_d\}$, if $\tau \in C\{x_1^{1/m}, \ldots, x_d^{1/m}\}$ is a q.o. branch, then the minimal polynomial $F \in K[y]$ of $\tau$ over $K$ has coefficients in the ring $C\{x_1, \ldots, x_d\}$ and defines the q.o. hypersurface parametrized by $\tau$.

In this paper we suppose that the germ $(Z, 0)$ is analytically irreducible, that is, the polynomial $f$ is irreducible in $C\{x_1, \ldots, x_d\}[y]$. The geometry of an irreducible q.o. polynomial is often expressed in terms of the combinatorics of the corresponding characteristic exponents, which we recall next.

If $\alpha, \beta \in Q^d$ we consider the preorder relation given by $\alpha \leq \beta$ if $\beta = \alpha + Q_{\geq 0}$. We also set $\alpha < \beta$ if $\alpha \leq \beta$ and $\alpha \neq \beta$. The notation $\alpha \not\leq \beta$ means that the relation $\alpha \leq \beta$ does not hold. In $Q^d \cup \{\infty\}$ we set that $\alpha < \infty$.

**Proposition 2.1** (Proposition 1.3). If $\zeta = \sum c_\lambda x^\lambda \in C\{x^{1/m}\}$ is a q.o. branch, there exist unique vectors $\lambda_1, \ldots, \lambda_g \in Q^d_{\geq 0}$ such that $\lambda_1 \leq \cdots \leq \lambda_g$ and the three conditions below hold. We set $\lambda_0 = 0$, $\lambda_{g+1} = \infty$, and introduce the lattices $M_0 := Z^d$, $M_j := M_{j-1} + Z\lambda_j$, for $j = 1, \ldots, g$.

(i) We have that $c_{\lambda_j} \neq 0$ for $j = 1, \ldots, g$.

(ii) If $c_\lambda \neq 0$, then the vector $\lambda$ belongs to the lattice $M_j$, where $j$ is the unique integer such that $\lambda_j \leq \lambda$ and $\lambda_{j+1} \not\leq \lambda$.

(iii) For $j = 1, \ldots, g$, the vector $\lambda_j$ does not belong to $M_{j-1}$.

If $\zeta \in C\{x^{1/m}\}$ is a fractional power series satisfying the three conditions above, then $\zeta$ is a q.o. branch.

**Definition 2.2.** The vectors $\lambda_1, \ldots, \lambda_g$ in Proposition 2.1 are called the characteristic exponents of the q.o. branch $\zeta$.

We also introduce some numerical invariants associated to the characteristic exponents. We denote by $n_j$ the index $[M_{j-1} : M_j]$ for $j = 1, \ldots, g$. We have that $e_0 := \deg_y f = n_1 \ldots n_g$ (see [18]). We define inductively the integers $e_j$ by the formula $e_{j-1} = n_j e_j$ for $j = 1, \ldots, g$. We set $e_0 = 0$. If $1 \leq j \leq g$ we denote by $\ell_j$ the number of coordinates of $\lambda_j$ which are different from zero.

We denote by $(\lambda_{j,1}, \ldots, \lambda_{j,d})$ the coordinates of the characteristic exponent $\lambda_j$ with respect to the canonical basis of $Q^d$, and by $\geq_{\text{lex}}$ the lexicographic order. We assume in this paper that

$$\lambda_{1,1}, \ldots, \lambda_{g,1} \geq_{\text{lex}} \cdots \geq_{\text{lex}} (\lambda_{1,d}, \ldots, \lambda_{g,d}),$$

a condition which holds after a suitable permutation of the variables $x_1, \ldots, x_d$. 

The q.o. branch ζ is normalized if the inequalities \(2\) hold and if \(λ_1\) is not of the form \((λ_{1,1},0,\ldots,0)\) with \(λ_{1,1} < 1\). Lipman proved that if the q.o. branch is not normalized, then there exists a normalized q.o. branch \(ζ'\) parametrizing the same germ \((Z,0)\) (see \([9\) Appendix]). Lipman and Gau studied q.o. singularities from a topological viewpoint. They proved that the embedded topological type of the hypersurface germ \((Z,0) \subset (\mathbb{C}^{d+1},0)\) is classified by the characteristic exponents of a normalized q.o. branch \(ζ'\) parametrizing \((Z,0)\); see \([9\) IS].

3. We introduce the following numbers in terms of the characteristic exponents:

\[
A_1 := \frac{1 + λ_{1,1}}{e_0 λ_{1,1}}, \quad A_2 := \frac{n_1(1 + λ_{2,1})}{e_1 (n_1 (1 + λ_{2,1}) - 1)}, \quad \text{and} \quad A_3 := \frac{1 + λ_{2,ℓ_1+1}}{e_1 λ_{2,ℓ_1+1}} \quad \text{if} \quad ℓ_1 < ℓ_2.
\]

With the above notation our main result is the following:

**Theorem 3.1.** Let \(f \in \mathbb{C}\{x_1,\ldots,x_d\}[y]\) be an irreducible quasi-ordinary polynomial. We assume that the associated characteristic exponents satisfy \(2\). Then the log canonical threshold of \(f\) at the origin is equal to:

\[
(3) \quad \lct(f) = \begin{cases} 
\min \{1, A_1\} & \text{if} \quad λ_{1,1} \neq \frac{1}{n_1}, \quad \text{or if} \quad g = 1, \\
\min \{A_2, A_3\} & \text{if} \quad λ_{1,1} = \frac{1}{n_1}, \quad g > 1 \quad \text{and} \quad ℓ_1 < ℓ_2, \\
A_2 & \text{if} \quad λ_{1,1} = \frac{1}{n_1}, \quad g > 1 \quad \text{and} \quad ℓ_1 = ℓ_2.
\end{cases}
\]

The number \(\lct(f)\) is determined by the embedded topological type of the germ defined by \(f = 0\) at the origin.

**Corollary 3.2.** With the hypothesis of Theorem 3.1, a singular polynomial \(f\) is log canonical if and only if \(g = 1\) and either \(λ_{1,i} \in \{1, \frac{1}{2}\}\) or \(λ_{1,i} = \frac{1}{n_i} \) for \(1 \leq i \leq ℓ_1\).

**Remark 3.3.** Suppose that \(λ_1 = (1/n_1,0,\ldots,0)\). By the inversion formulae of \([18]\) the germ \((Z,0)\) is parametrized by a normalized q.o. branch \(ζ'\) with characteristic exponents \(λ'_i = (n_1(1 + λ'_{i+1,1} - 1/n_1),λ_{i+1,2},\ldots,λ_{i+1,d})\) for \(i = 1,\ldots,g - 1\), in particular \(λ'_{i,1} > 1\). If \(f'\) is the quasi-ordinary polynomial defined by \(ζ'\) we get that \(\lct(f) = \lct(f')\) since both are square-free and define the same germ.

**Example 3.4.** If \(n = 2\) and \(f \in \mathbb{C}\{x\}[y]\) defines a singular irreducible plane germ, then \(\lct(f) = \frac{1 + λ_1}{e_0 λ_{1,1}}\). This example is well known; see \([12]\). The log canonical thresholds of plane curve singularities have been considered several times. For example, \([16]\) gave an explicit formula for this invariant in the case of two branches and explained how to compute it for more branches. The case of transversal branches is treated with the help of adjoint ideals in \([8]\). The general non-reduced case is done in \([3]\). See also \([2]\).

4. Notation. We introduce a sequence of vectors \(α_1,\ldots,α_g \in \mathbb{Q}_{≥0}^d\) in terms of the characteristic exponents \(λ_1,\ldots,λ_g\). We denote by \((q^{(j)}_i/p^{(j)}_i)\) the coordinates of \(α_j\) in terms of the canonical basis of \(\mathbb{Q}^d\), with \(\gcd(q^{(j)}_i,p^{(j)}_i) = 1\). The coordinates of \(α_j\) are defined inductively by

\[
q^{(1)}_i/p^{(1)}_i := λ_{1,i} \quad \text{and} \quad q^{(j)}_i/p^{(j)}_i := p^{(1)}_i \cdots p^{(j-1)}_i (λ_{j,i} - λ_{j-1,i}).
\]

The sequences \(\{λ_{j,i}\}_{j=1}^g\) and \(\{α_j\}_{j=1}^g\) determine each other and by Proposition \(2\) we get that \(p^{(j)}_i\) divides \(n_j\) for \(1 \leq i \leq d\).
Definition 4.1. The following formulas define pairs of integers \( (B_i^{(j)}, b_i^{(j)}) \) for \( 1 \leq i \leq d \) and \( 1 \leq j \leq g \):

\[
\begin{align*}
  b_i^{(1)} &= p_i^{(1)} + q_i^{(1)}, \\
  B_i^{(1)} &= e_0 q_i^{(1)}, \\
  b_i^{(j)} &= p_i^{(j)} b_i^{(j-1)} + q_i^{(j)}, \\
  B_i^{(j)} &= p_i^{(j)} B_i^{(j-1)} + e_{j-1} q_i^{(j)}.
\end{align*}
\]

Remark 4.2. Notice that \( B_i^{(j)} = 0 \) if and only if \( \ell_j < i \leq d \) and in that case \( b_i^{(j)} = 1 \).

We also have that \( A_1 = \frac{b_1^{(1)}}{B_1^{(1)}}, A_2 = \frac{b_2^{(2)}}{B_2^{(2)}} \) and \( A_3 = \frac{b_3^{(2)}}{B_3^{(2)}} \).

5. In this section we give some properties of the set of the quotients \( \frac{b_i^{(j)}}{B_i^{(j)}} \).

The following formulas are useful in the discussion below. The first one is a consequence of Proposition 2.1:

\[
0 = \ell_0 < \ell_1 \leq \cdots \leq \ell_g \leq d.
\]

If \( \ell_{j-1} < \ell_j \) we deduce from the inequalities (2) that

\[
\begin{align*}
  \lambda_{j, \ell_{j-1}+1} &\geq \cdots \geq \lambda_{j, \ell_j} \quad \text{and} \quad \lambda_{j, \ell_{j+1}} = \cdots = \lambda_{j, d} = 0.
\end{align*}
\]

Lemma 5.1. We have the following inequalities for \( 1 \leq k \leq g \) and \( \ell_{k-1} < i \leq \ell_k \):

\[
\begin{align*}
  \frac{b_i^{(k)}}{B_i^{(k)}} &\leq \frac{b_i^{(k)}}{B_i^{(k+1)}}, \\
  \frac{1}{e_{k-1}} &\leq \frac{b_i^{(k)}}{B_i^{(k)}};
\end{align*}
\]

in addition, if \( \frac{q_i^{(k)}}{p_i^{(k)}} > \frac{1}{n_k} \), then we have

\[
\frac{b_i^{(k)}}{B_i^{(k)}} \leq \frac{1}{e_k};
\]

if \( k < g \) and \( \frac{q_i^{(k)}}{p_i^{(k)}} = \frac{1}{n_k} \), then we have

\[
\begin{align*}
  \frac{1}{e_k} &< \frac{b_i^{(k+1)}}{B_i^{(k+1)}} < \frac{1}{e_{k+1}};
\end{align*}
\]

and if \( k < g \) and \( \frac{q_i^{(k-1)+1}}{p_i^{(k-1)+1}} = \frac{1}{n_k} \), then we have

\[
\begin{align*}
  \frac{b_i^{(k-1)+1}}{B_i^{(k-1)+1}} &\leq \frac{b_i^{(k+1)}}{B_i^{(k+1)}}.
\end{align*}
\]

Proof. Notice first that if \( \ell_{k-1} < i \leq \ell_k \), then \( q_i^{(j)} = 0 \) for \( 1 \leq j < k \); hence we obtain that \( b_i^{(k)} = p_i^{(k)} + q_i^{(k)} \) and \( B_i^{(k)} = e_{k-1} q_i^{(k)} \). We deduce (6) from (5) and the definitions. We get (9) from the definitions and the inequality

\[
\begin{align*}
  \frac{1}{e_{k-1}} < \frac{1}{e_k} \left( 1 + \frac{1}{q_i^{(k)}} \right) = \frac{1}{e_k} \left( \frac{1}{n_k} + \frac{1}{n_k q_i^{(k)}} \right) = \frac{b_i^{(k)}}{B_i^{(k)}}.
\end{align*}
\]
If in addition $\frac{q_i^{(k)}}{p_i^{(k)}} > \frac{1}{n_k}$, then we get that $\frac{q_i^{(k)}}{p_i^{(k)}} \geq \frac{2}{n_k}$. Then we deduce the inequality \[ \text{(9)} \] from the expression for $B_i^{(k)}$ given at formula (11) by using that $n_k \geq 2$.

If in addition $k < g$ and $\frac{q_i^{(k)}}{p_i^{(k)}} = \frac{1}{n_k}$, we get from the definitions that

\[ \frac{b_i^{(k+1)}}{B_i^{(k+1)}} = \frac{1}{e_k} \left( 1 + \frac{1}{n_k + \frac{q_i^{(k+1)}}{p_i^{(k+1)}}} \right). \]

This implies that $\frac{1}{e_k} < \frac{q_i^{(k+1)}}{B_i^{(k+1)}}$. By formula (12) and the inequalities $\frac{q_i^{(k+1)}}{p_i^{(k+1)}} \geq \frac{1}{n_k+1}$, $n_k, n_{k+1} \geq 2$ and $e_k = n_{k+1}e_{k+1}$, we deduce that

\[ \frac{b_i^{(k+1)}}{B_i^{(k+1)}} = \frac{1}{e_k} \left( 1 + \frac{1}{n_k+1 + \frac{q_i^{(k+1)}}{p_i^{(k+1)}}} \right) \leq \frac{1}{e_k} \left( 1 + \frac{1}{n_k+1 + \frac{1}{n_k+1n_k+1}} \right) < \frac{1}{e_k}. \]

This proves that inequality \[ \text{(9)} \] holds.

Finally, notice that $\frac{1}{n_k} \leq \frac{q_i^{(k)}}{p_i^{(k)}} \leq \frac{q_i^{(k)}}{p_i^{(k)}} = \frac{1}{n_k}$. We deduce from this and formula (12) that \[ \text{(10)} \] holds.

It is easy to see from the inductive definition of the pairs $(b_i^{(k)}, B_i^{(k)})$ that

\[ \frac{b_i^{(k)}}{B_i^{(k)}} \leq \frac{b_i^{(k+1)}}{B_i^{(k+1)}} \iff q_i^{(k+1)}e_k b_i^{(k)} \leq q_i^{(k+1)} B_i^{(k)}, \]

for $\ell_{k-1} < i \leq \ell g$ and $1 \leq k < g$.

**Lemma 5.2.** If $\ell_{k-1} < i \leq \ell_k$ and $\frac{q_i^{(k)}}{p_i^{(k)}} > \frac{1}{n_k}$, then the following inequality holds:

\[ \frac{b_i^{(k)}}{B_i^{(k)}} \leq \frac{b_j^{(j)}}{B_j^{(k)}} \quad \text{for} \ 1 \leq k \leq j \leq g. \]

**Proof.** We set $R_j := B_i^{(j)} - e_j b_i^{(j)}$. By the equivalence (13) it is enough to prove that the inequality $R_j \geq 0$ holds for $k \leq j \leq g - 1$. We prove this by induction.

For $j = k$ we have the equivalences

\[ e_k b_i^{(k)} \leq B_i^{(k)} \iff e_k (p_i^{(k)} + q_i^{(k)}) \leq e_{k-1} q_i^{(k)} \iff p_i^{(k)} + q_i^{(k)} \leq n_k q_i^{(k)} \iff \frac{1}{n_k - 1} \leq q_i^{(k)}. \]

We deduce that the inequality

\[ R_k = B_i^{(k)} - e_k b_i^{(k)} \geq 0 \]

holds since $n_k \geq 2$ and $\frac{q_i^{(k)}}{p_i^{(k)}} \geq \frac{2}{n_k}$ by hypothesis.

Assume that $k < j$ and $R_{j-1} \geq 0$. Using that $e_{j-1} = n_j e_j$, we get the following inequalities:

\[ B_i^{(j-1)} - e_j b_i^{(j-1)} \geq B_i^{(j-1)} - e_{j-1} b_i^{(j-1)} = R_{j-1} \geq 0. \]
and

\[ R_j = p_i^{(j)} \left( B_i^{(j-1)} - e_j b_i^{(j-1)} \right) + e_j q_i^{(j)} (n_j - 1) \geq e_j q_i^{(j)} (n_j - 1) \geq 0. \]

This completes the proof. \( \square \)

**Lemma 5.3.** If \( \ell_{k-1} < i \leq \ell_k \) and if \( q_i^{(k)} p_i^{(n-k)} = \frac{1}{n_k} \), then the following inequality holds:

\[ b_i^{(k+1)} B_i^{(k+1)} \leq b_i^{(j)} B_i^{(j)} \text{ for } 1 \leq k \leq j \leq g. \] (17)

**Proof.** To compare \( b_i^{(k+1)} B_i^{(k+1)} \) and \( b_i^{(k)} B_i^{(k)} \), we use the expressions (12) and (11).

By (13), it is enough to prove that \( R_j := B_i^{(j)} - e_j b_i^{(j)} \geq 0 \) for \( k < j < g \). We prove this by induction on \( j \). The inequality \( R_{k+1} \geq 0 \) is equivalent to

\[ e_{k+1} (p_i^{(k+1)} b_i^{(k)} + q_i^{(k+1)}) \leq p_i^{(k+1)} B_i^{(k)} + e_k q_i^{(k+1)}. \] (18)

By hypothesis we have \( B_i^{(k)} = e_{k-1} \) and \( b_i^{(k)} = 1 + n_k \); hence (18) holds since \( e_{k-1} = n_k e_k = n_k n_{k+1} e_{k+1} \) and \( n_k, n_{k+1} \geq 2 \).

If \( k + 1 < j < g \), then we deduce from the induction hypothesis that \( R_j \geq 0 \) as in Lemma 5.2 \( \square \)

We set

\[ B := \{1\} \cup \left\{ \frac{b_i^{(j)}}{B_i^{(j)}} \mid 1 \leq i \leq \ell_j \text{ and } 1 \leq j \leq g \right\} \subset \mathbb{Q}_{\geq 0}. \]

**Proposition 5.4.** The minimum of the set \( B \) is the number defined by the right-hand side of formula (3).

**Proof.** We deal first with the case \( q_i^{(1)} p_i^{(n)} > \frac{1}{m_1} \).

If \( 1 \leq i \leq \ell_1 \) and \( q_i^{(1)} p_i^{(n)} > \frac{1}{m_1} \), we get the following inequalities for \( 1 \leq j \leq g \):

\[ A_1 = \frac{b_i^{(1)}}{B_i^{(1)}} \leq \frac{b_i^{(1)}}{B_i^{(1)}} \leq \frac{b_i^{(j)}}{B_i^{(j)}}, \]

If \( 1 < i \leq \ell_1 \) and \( q_i^{(1)} p_i^{(n)} = \frac{1}{m_1} \), we obtain that \( A_1 = \frac{b_i^{(1)}}{B_i^{(1)}} \leq 1 \), and hence \( A_1 = \frac{b_i^{(1)}}{B_i^{(1)}} \leq \frac{b_i^{(j)}}{B_i^{(j)}} \), for \( 1 \leq j \leq g \).

Suppose now that \( 1 < k \leq j \leq g \) and \( \ell_{k-1} < i \leq \ell_k \). We have

\[ A_1 = \frac{b_i^{(1)}}{B_i^{(1)}} \leq \frac{1}{e_1} \leq \frac{1}{e_k} \leq \frac{b_i^{(k)}}{B_i^{(k)}} \leq \frac{b_i^{(k+1)}}{B_i^{(k+1)}} \leq \frac{b_i^{(j)}}{B_i^{(j)}}, \]

Formula (14) in the line above only applies if \( q_i^{(k)} p_i^{(n)} > \frac{1}{m_k} \). Otherwise \( q_i^{(k)} p_i^{(n)} = \frac{1}{m_k} \) and we use that

\[ \frac{1}{e_1} < 
\frac{1}{e_k} < \frac{b_i^{(k+1)}}{B_i^{(k+1)}} \leq \frac{b_i^{(j)}}{B_i^{(j)}}, \]

\[ \frac{1}{e_1} < 
\frac{1}{e_k} < \frac{b_i^{(k+1)}}{B_i^{(k+1)}} \leq \frac{b_i^{(j)}}{B_i^{(j)}}, \]

\[ \frac{1}{e_1} < 
\frac{1}{e_k} < \frac{b_i^{(k+1)}}{B_i^{(k+1)}} \leq \frac{b_i^{(j)}}{B_i^{(j)}}, \]

\[ \frac{1}{e_1} < 
\frac{1}{e_k} < \frac{b_i^{(k+1)}}{B_i^{(k+1)}} \leq \frac{b_i^{(j)}}{B_i^{(j)}}, \]
This finishes the proof in the case of $Z_{\text{mot},f}(T)$. By [5] it follows that $q_{i}^{(1)} = \frac{1}{n_{i}}$ for $1 \leq i \leq \ell_{1}$. We get the inequalities for $1 \leq i \leq \ell_{1}$ and $1 \leq j \leq g$,

$$A_{2} = \frac{b_{i}^{(2)}}{B_{1}^{(2)}} \leq \frac{b_{i}^{(2)}}{B_{i}^{(2)}} \leq \frac{b_{i}^{(j)}}{B_{i}^{(j)}}. \tag{20}$$

If $\ell_{1} < \ell_{2}$ and $\frac{q_{i+1}^{(2)}}{p_{i+1}^{(2)}} > \frac{1}{n_{2}}$, then we deduce the following inequalities for $2 \leq j \leq g$ and $\ell_{1} < i \leq \ell_{2}$:

$$A_{3} = \frac{b_{i}^{(2)}}{B_{1}^{(2)}} \leq \frac{b_{i}^{(2)}}{B_{i}^{(2)}} \leq \frac{b_{i}^{(j)}}{B_{i}^{(j)}}. \tag{10}$$

If $\ell_{1} < \ell_{2}$ and $\frac{q_{i+1}^{(2)}}{p_{i+1}^{(2)}} = \frac{1}{n_{2}}$, then for $2 \leq j \leq g$ and $\ell_{1} < i \leq \ell_{2}$ we get $\frac{q_{i}^{(2)}}{p_{i}^{(2)}} = \frac{1}{n_{2}}$ and

$$A_{2} = \frac{b_{i}^{(2)}}{B_{1}^{(2)}} \leq \frac{1}{e_{2}} \frac{b_{i}^{(3)}}{B_{i}^{(3)}} \leq \frac{b_{i}^{(j)}}{B_{i}^{(j)}}. \tag{13}$$

For $k \geq 3$ and $\ell_{k-1} < i \leq \ell_{k}$ we have that

$$A_{2} = \frac{b_{i}^{(2)}}{B_{1}^{(2)}} \leq \frac{1}{e_{2}} \frac{k_{i} \geq 3}{e_{k-1}} \frac{1}{e_{k-1}} \frac{b_{i}^{(k)}}{B_{i}^{(k)}}. \tag{17}$$

The remaining candidates for the minimum of $\mathcal{B}$ are discarded by [6], [14], and [17]. This completes the proof. \hfill \Box

6. In this paper we use a relation between the log canonical threshold and the poles of the motivic zeta function.

Let $f$ be as in Section 1. The local motivic zeta function and the local topological zeta function of $f$ of Denef and Loeser (see for example [7]) are

$$Z_{\text{mot},f}(T)_{0} := \sum_{\emptyset \neq I \subseteq J} (\mathbb{L} - 1)^{|I| - 1}[E_{I}^{\circ} \cap \mu^{-1}(0)] \cdot \prod_{i \in I} \frac{\mathbb{L}^{-\frac{k_{i}+1}{a_{i}}}}{1 - \mathbb{L}^{-\frac{k_{i}+1}{a_{i}}}} T_{a_{i}}^{-1},$$

$$Z_{\text{top},f}(s) := \sum_{\emptyset \neq I \subseteq J} \chi(E_{I}^{\circ} \cap \mu^{-1}(0)) \cdot \prod_{i \in I} \frac{1}{a_{i}s + k_{i} + 1},$$

where $E_{i}^{\circ} = (\bigcap_{i \in I} E_{i}) - \bigcup_{i \notin I} E_{i}$, the symbol $\emptyset$ represents the class of $\cdot$ in the Grothendieck ring $\mathcal{K}_{0}(\text{Var}_{\mathbb{C}})$ of complex algebraic varieties, $\mathbb{L}$ is the class $[\mathbb{A}^{1}]$, and $\chi$ is the Euler-Poincaré characteristic. $Z_{\text{mot},f}(T)_{0}$ and $Z_{\text{top},f}(s)$ are independent of the choice of the log resolution $\mu$. The set of poles of $Z_{\text{mot},f}(\mathbb{L}^{-s})_{0}$ and the set of poles of $Z_{\text{top},f}(s)$ are subsets of $\{-k_{i}+1/a_{i} \mid i \in J\}$.

To compute the log canonical threshold of irreducible quasi-ordinary singularities we will use the following result.

**Theorem 6.1** ([14], p. 18; see also [20], 2.7 and 2.8, or [14], 6.3). The biggest pole of $Z_{\text{mot},f}(\mathbb{L}^{-s})_{0}$ is equal to $-\text{lct}_{0}(f)$.

7. We recall some results obtained by the last two authors in [11]. We use the notation of Section 2 and also the definition of the set $\mathcal{B}$ in formula (19). The following result follows from [11], Corollary 3.17].
Theorem 7.1. If \( f \in \mathbb{C}\{x_1, \ldots, x_d\}[y] \) is an irreducible quasi-ordinary polynomial, then the poles of \( Z_{\text{mot},f}(\mathbb{L}^{-\delta})_0 \) are contained in the set \( \{-\frac{b}{\mathcal{B}} | \frac{b}{\mathcal{B}} \in \mathcal{B}\} \).

Remark 7.2. Theorem 7.1 is proved by giving a formula for the motivic zeta function in terms of the contact of the jets of arcs with \( f \). The proof uses the change of variable formula for motivic integrals applied to a particular log resolution of \( \mu \) this log resolution arises also in [4] with a different method; see [11] for a comparison.

Proof of Theorem 3.1 Since \( \text{lct}_0(f) \) is by definition the minimum of \((k_i + 1)/a_i\) for \( i \in J \), it follows from Theorem 6.1 Theorem 7.1 and Remark 7.2 that \( \text{lct}_0(f) = \min \mathcal{B} \). The result follows then from Proposition 5.4.

Proof of Corollary 3.2 If \( f \) is singular and log canonical, then \( 1 \leq \frac{b^{(1)}_{\mathcal{B}}}{p^{(1)}_{\mathcal{B}}} = \frac{1}{e_0}(1 + \frac{p^{(1)}_{\mathcal{B}}}{q^{(1)}_{\mathcal{B}}}) \). Since \( \frac{q^{(1)}_{\mathcal{B}}}{p^{(1)}_{\mathcal{B}}} \geq \frac{1}{n_1} \), we deduce that \( e_0 - 1 = n_1 \ldots n_g - 1 \leq \frac{p^{(1)}_{\mathcal{B}}}{q^{(1)}_{\mathcal{B}}} \leq n_1 \). This implies that \( g = 1 \). If \( n_1 = 2 \), there are two possible cases: \( \lambda_1 = (1, \ldots, 1, 1/2, \ldots, 1/2, 0, \ldots, 0) \) or \( \lambda_1 = (1/2, \ldots, 1/2, 0, \ldots, 0) \). If \( n_1 > 2 \), we must have \( p^{(1)}_{\mathcal{B}} = n_1 \) and \( q^{(1)}_{\mathcal{B}} = 1 \), since \( p^{(1)}_{\mathcal{B}} \) divides \( n_1 \). By [3] we get that \( \lambda_1 = (\frac{1}{n_1}, \ldots, \frac{1}{n_1}, 0, \ldots, 0) \).

9. We end this paper with some examples.

Example 9.1. Let \( \lambda_1 = (1/3, 1/3), \lambda_2 = (7/6, 2/3) \). A polynomial with these characteristic exponents is for example \( f = (z^3 - xy)^2 - x^3y^2z^2 \). We have \( n_1 = 3 \) and \( n_2 = 2 \). By Theorem 3.1 the log canonical threshold comes from \( \lambda_{2,1} \) and equals \( A_2 = 13/22 \). Indeed, \( \frac{b^{(1)}_{\mathcal{B}}}{p^{(1)}_{\mathcal{B}}} = 2/3, \frac{b^{(2)}_{\mathcal{B}}}{p^{(2)}_{\mathcal{B}}} = 13/22, \frac{b^{(2)}_{\mathcal{B}}}{p^{(2)}_{\mathcal{B}}} = 5/8 \), and the minimum of these is 13/22.

Example 9.2. Let us consider a q.o. polynomial with characteristic exponents \( \lambda_1 = (1/2, 1/2, 0) \) and \( \lambda_2 = (2/3, 2/3, 11/3) \). For instance \( f = (y^2 - x_1x_2)^3 - (y^2 - x_1x_2)x_1^6x_2^6x_3^{11} \). We have that \( n_1 = 2 \) and \( n_2 = 3 \) and \( \mathcal{B} = \{1, 1/2, 10/21, 14/33\} \). We get \( \text{lct}_0(f) = 14/33 = A_3 \).
