Abstract. We study the Poisson problem $-\Delta u = f$ and the Helmholtz problem $-\Delta u + \lambda u = f$ in bounded domains with angular corners in the plane and $u = 0$ on the boundary. On non-convex domains of this type, the solutions are in the Sobolev space $H^1$ but not in $H^2$ in general, even though $f$ may be very regular. We formulate these as variational problems in weighted Sobolev spaces and prove existence and uniqueness of solutions in what would be weighted counterparts of $H^2 \cap H^1_0$.

The specific forms of our variational formulations are motivated by, and are particularly suited to, applying a finite element scheme for solving the time-dependent Navier-Stokes equations of fluid mechanics.

1. Introduction. Consider the Poisson problem in an open and bounded domain $\Omega$ in $\mathbb{R}^n$:

$$
-\Delta u = f \quad \text{in } \Omega,
$$

$$
u = g \quad \text{on } \partial \Omega.
$$

The operator $A : u \mapsto (f, g)$ is an isomorphism from $H^s(\Omega)$ to $H^{s-2}(\Omega) \times H^{s-1/2}(\partial \Omega)$ for $s \geq 2$, provided that the boundary is of class $C^s$. See, e.g., Lions and Magenes [18, Theorem 5.5.4], Gilbarg and Trudinger [8, Theorem 8.13], Evans [7, Theorem 6.3.5]. Much work has been done on extending this to cases where the regularity of the boundary is less than $C^s$. A wealth of information about this and further references to the literature...
are available in Kondrat’ev [12], Kondrat’ev and Oleĭnik [13], Grisvard [9, 10], Dauge [4], Kufner [16], Kufner and Sändig [17], and Kozlov, Maz’ya, and Roßmann [14, 15]. For results specific to polyhedral domains, see von Petersdorff and Stephan [25], Nicaise [20], and the survey article by Dauge [6].

In this work we present variational formulations for the Poisson problem \((-\Delta u = f)\) and the Helmholtz problem \((-\Delta u + \lambda u = f)\) on non-smooth domains in \(\mathbb{R}^2\) by applying the machinery for weighted Sobolev spaces developed in [12, 14, 17]. The novel aspect of this study is the non-traditional variational formulation of two elliptic problems (see (3.2), (3.3), (4.2), and (4.4)) which are motivated by a desire to extend the numerical scheme for solving the Navier-Stokes equations developed by Liu, Liu, and Pego [19] to non-smooth domains. Their algorithm, which calls for solving a Poisson problem in \(H^1\) and a Helmholtz problem in \(H^2\) at each discretized time step, converges and is unconditionally stable on domains with sufficiently smooth boundaries. A naive application of the algorithm in non-convex polygonal domains (flow over a step, for example) produces incorrect solutions because the velocity is not in \(H^2\) near reentrant corners. We propose a modified version of the algorithm that applies appropriate weights near reentrant corners to compensate for singularities. Our analysis of the Poisson and Helmholtz problems leads to a version of the algorithm in [19] in weighted Sobolev spaces that is suitable for solving the Navier-Stokes equations in polygonal domains with reentrant corners.

The plan of this article is as follows. In Section 2 we summarize definitions and theorems pertaining to weighted Sobolev spaces, mostly from [14], that will be needed in the sequel. In Section 3 we introduce our formulation of the Poisson problem (see (3.2) and (3.3)) that extends the traditional \(H^2\) formulation to domains with corners. We show the existence and uniqueness of solutions and establish their relationship to the usual \(H^1\) formulation. We repeat this for equations of Helmholtz type in Section 4 (see (4.2) and (4.4)). In Section 5 we apply the variational formulations developed in the previous sections to adapt the iterative algorithm of Liu, Liu, and Pego [19] to solving the time-dependent Navier-Stokes equations to non-convex polygonal domains. The well-posedness of the modified algorithm follows from our analysis of the Poisson and Helmholtz problems in Sections 3 and 4. We do not address the issue of convergence of the iterates in this article. We do, however, provide numerical evidence in Section 6 that the iteration does produce the expected solution. In addition to reporting results for the Navier-Stokes equations, Section 6 contains convergence studies of two benchmark problems for the Poisson and Helmholtz equations on L-shaped domains, where numerical solutions are compared to a priori known exact solutions. These serve to validate our weighted Sobolev space finite element solver which is described elsewhere [22]. For the Poisson and Helmholtz problems, the convergence of our finite element method is shown in [23] and error estimates and optimal rates of convergence are established in [24].

To put this work in context, let us note that there are at least two distinct approaches to dealing with corner singularities. In one approach, as expounded in Grisvard [10], the solution is decomposed into the sum of a “regular part” which is in \(H^2\) or better, and a “singular part” which is in \(H^1\). Aziz and Kellogg [1] follow a similar method to construct distributional solutions in \(L_2\) corresponding to rough data. In the other approach, as exemplified by [14], the solution is considered as a whole, as a member of
an extended function space that accommodates the singularities and enables the use of variational formulations in the familiar functional analytic settings. The work presented here follows the latter approach.

2. Preliminaries. The weighted Sobolev spaces in a plane wedge are defined in Section 2.1. These are extended to general bounded domains with angular points in Section 2.2. In Section 2.3 we recall a regularity result for the Poisson problem in domains with angular points [14] which will be used extensively in the proofs of our analytical results.

2.1. Weighted Sobolev spaces in a wedge. Let $\mathcal{K} = \{(x_1, x_2) \in \mathbb{R}^2 : r > 0, 0 < \theta < \omega\}$ be a plane wedge centered at the origin. Here $r$, $\theta$ are the polar coordinates of the point $(x_1, x_2)$ and $\omega \in (0, 2\pi)$. For integer $l \geq 0$ and real $\beta$, the space $V^l_{2,\beta}(\mathcal{K})$ is defined as the closure of $C_0^\infty(K \setminus \{0\})$ with respect to the norm

$$
\|u\|_{V^l_{2,\beta}(\mathcal{K})} = \left( \int_{\mathcal{K}} \sum_{|\alpha| \leq l} r^{2(\beta - l + |\alpha|)} |D_\alpha^2 u|^2 \, dx \right)^{1/2},
$$

where $D_x^\alpha = \partial^{|\alpha|}/\partial x_1^{\alpha_1} \partial x_2^{\alpha_2}$, $|\alpha| = \alpha_1 + \alpha_2$.

If $l \geq 1$, $V^{l-1/2}_{2,\beta}(\partial \mathcal{K})$ is the space of traces of functions from $V^l_{2,\beta}(\mathcal{K})$ on the boundary $\partial \mathcal{K}$ equipped with the norm

$$
\|u\|_{V^{l-1/2}_{2,\beta}(\partial \mathcal{K})} = \inf_{v \in V^l_{2,\beta}(\mathcal{K})} \{ \|v\|_{V^l_{2,\beta}(\mathcal{K})} : v|_{\partial \mathcal{K}} = u \}.
$$

We call $\mathcal{K}$, or any translation and rotation of it, a plane wedge of angle $\omega$ and the spaces $V^l_{2,\beta}(\mathcal{K})$, $V^{l-1/2}_{2,\beta}(\partial \mathcal{K})$ accordingly.

2.2. Weighted Sobolev spaces in bounded domains with angular points. Let $\mathcal{G} \subset \mathbb{R}^2$ be a bounded domain. Suppose that there exists a finite set $S = \{x^1, \ldots, x^d\}$ of points on the boundary $\partial \mathcal{G}$ such that $\partial \mathcal{G} \setminus S$ is smooth. Also, assume that for each of the points $x^j$, $j = 1, \ldots, d$, there exists a neighborhood $U_j$ such that $\mathcal{G} \cap U_j = K_j \cap U_j$, where $K_j$ is a wedge with vertex $x^j$. Such a domain is called a domain with angular points.

Let $\zeta_j$, $j = 1, \ldots, d$, be infinitely differentiable functions in $\mathcal{G}$, $0 \leq \zeta_j(x) \leq 1$, equal to one in a neighborhood of $x^j$ and to zero in $\mathcal{G} \setminus U_j$, and set $\zeta_0 = 1 - \zeta_1 - \cdots - \zeta_d$. The neighborhoods $U_j, j = 1, \ldots, d$, are chosen sufficiently small to be disjoint. The space $V^l_{2,\beta}(\mathcal{G})$, where $\beta = (\beta_1, \ldots, \beta_d) \in \mathbb{R}^d$ and $l$ is a nonnegative integer, is defined as the set of all functions on $\mathcal{G}$ such that $\zeta_0 u \in H^l(\mathcal{G})$ and $\zeta_j u \in V^l_{2,\beta_j}(K_j)$, $j = 1, \ldots, d$. Here and elsewhere $H^l(\mathcal{G})$ is the usual Sobolev space of functions on $\mathcal{G}$ whose weak derivatives of up to order $l$ are square integrable. Equipped with the norm

$$
\|u\|_{V^l_{2,\beta}(\mathcal{G})} = \left( \|\zeta_0 u\|_{H^l(\mathcal{G})}^2 + \sum_{j=1}^d \|\zeta_j u\|_{V_{2,\beta_j}(K_j)}^2 \right)^{1/2},
$$

\footnote{This norm is equivalent to the norm \(\|u\|_{V_{2,\beta}(\mathcal{G})} = \|\zeta_0 u\|_{H^l(\mathcal{G})} + \sum_{j=1}^d \|\zeta_j u\|_{V_{2,\beta_j}(K_j)}\) used in \[14\].}
the space $V_{2,\beta}^l(\mathcal{G})$ is complete. We use the notation $L_{2,\beta}(\mathcal{G})$ for the space $V_{2,\beta}^0(\mathcal{G})$ and define the inner product as

$$(u,v)_{L_{2,\beta}(\mathcal{G})} = \int_\mathcal{G} \zeta_\beta^2 uv \, dx + \sum_{j=1}^d \int_{K_j} r_j^{2\beta} \zeta_\beta^2 uv \, dx,$$

where $r_j$ is the distance from vertex $x_j$.

For $l \geq 1$, the space $V_{2,\beta}^{l-1/2}(\partial\mathcal{G})$ is defined as the space of traces of functions from $V_{2,\beta}^l(\mathcal{G})$ on $\partial\mathcal{G} \setminus S$. The norm in $V_{2,\beta}^{l-1/2}(\partial\mathcal{G})$ is

$$\|u\|_{V_{2,\beta}^{l-1/2}(\partial\mathcal{G})} = \inf_{v \in V_{2,\beta}^l(\mathcal{G})} \{\|v\|_{V_{2,\beta}^l(\mathcal{G})} : v|_{\partial\mathcal{G}\setminus S} = u\}.$$

We denote by $\hat{V}_{2,\beta}^l(\mathcal{G})$ the subspace of zero trace functions from $V_{2,\beta}^l(\mathcal{G})$,

$$\hat{V}_{2,\beta}^l(\mathcal{G}) = \{u \in V_{2,\beta}^l(\mathcal{G}) : u|_{\partial\mathcal{G}} = 0\}.$$

The following imbedding property will be needed in the sequel.

**Lemma 2.1** ([14, Lemma 6.2.1]). Let $\beta = (\beta_1, \ldots, \beta_d)$, $\gamma = (\gamma_1, \ldots, \gamma_d)$ be real $d$-tuples. If $l_2 \geq l_1 \geq 0$ and $\beta_j - l_2 \leq \gamma_j - l_1$ for $j = 1, \ldots, d$, then the space $V_{2,\beta}^{l_2}(\mathcal{G})$ is continuously imbedded into $V_{2,\gamma}^{l_1}(\mathcal{G})$. If, moreover, $l_2 > l_1 \geq 0$, $\beta_j - l_2 < \gamma_j - l_1$ for $j = 1, \ldots, d$, then this imbedding is compact.

2.3. *The Poisson problem in a plane domain with angular points.* Let $\mathcal{G} \subset \mathbb{R}^2$ be a bounded domain with angular points $x^1, \ldots, x^d$ with interior angles $\alpha_j \in (0, 2\pi)$, $j = 1, \ldots, d$. Consider the problem

$$-\Delta u = f \quad \text{in} \ \mathcal{G},$$
$$u = g \quad \text{on} \ \partial\mathcal{G},$$

and denote the operator of this problem by $A$.

**Theorem 2.2** ([14, Theorem 6.6.1]). The operator

$$A : V_{2,\beta}^l(\mathcal{G}) \to V_{2,\beta}^{l-2}(\mathcal{G}) \times V_{2,\beta}^{l-1/2}(\partial\mathcal{G}),$$

where $l \geq 2$ and $\beta = (\beta_1, \ldots, \beta_d) \in \mathbb{R}^d$, is an isomorphism if and only if $-\pi/\alpha_j < l_1 - \beta_j < \pi/\alpha_j$ for $j = 1, \ldots, d$.

Theorem 2.2 is a natural extension of the classical result on the $H^l$-regularity of the Poisson problem in smooth domains; see Lions and Magenes [18, Theorem 5.5.4], Gilbarg and Trudinger [8, Theorem 8.13], Evans [7, Theorem 6.3.5]. The following corollary is an immediate consequence of Theorem 2.2.

**Corollary 2.3.** If $-\pi/\alpha_j < l_1 - \beta_j < \pi/\alpha_j$ for $j = 1, \ldots, d$, then the operator $\Delta : V_{2,\beta}^l(\mathcal{G}) \to V_{2,\beta}^{l-2}(\mathcal{G})$, where $l \geq 2$, $\beta = (\beta_1, \ldots, \beta_d) \in \mathbb{R}^d$, is an isomorphism.
3. Variational formulation of the Poisson problem in $V^2_{2, \beta}(G)$. As noted in the introduction, in domains with smooth boundary or convex domains, the solution of the Poisson problem belongs to $H^2$, provided the force term is square integrable $[7, 8, 18]$. In domains with reentrant corners, solutions suffer a loss of regularity due to singularities that develop at corners. For example, near a reentrant corner with interior angle $\alpha > \pi$, the solution behaves like $r^{\pi/\alpha}$ (where $r$ is the distance from the reentrant corner). Thus, it belongs to the Sobolev space $H^{1+\frac{\pi}{\alpha}-\varepsilon} \supset H^2$; see, e.g., $[2, 10]$. In this section we investigate variational formulations in weighted Sobolev spaces $V^2_{2, \beta}$, where the application of weights at reentrant corners compensates for the solution’s singularities.

We present the formulation in two equivalent variants. In the first variant, the weights are confined to isolated neighborhoods of reentrant vertices through cut-off functions that were introduced in Section 2.2. In the second variant, the cut-off functions are removed so that the weight from each corner propagates throughout the domain. The first variant is particularly appealing for computing, e.g., with finite elements, because the effects of weights remain local and do not “pollute” the bulk of the interior region. The second variant is more appealing from the analysis point of view because the clutter of the cut-off functions is removed.

Section 5 contains an application of these results to an iterative algorithm for solving the time-dependent Navier-Stokes equations.

3.1. Variational formulation with local weights. We consider the Poisson problem with homogeneous Dirichlet boundary conditions

$$
-\Delta u = f \quad \text{in } G,
$$
$$
u = 0 \quad \text{on } \partial G,
$$
(3.1)
in a bounded domain $G \subset \mathbb{R}^2$ with corners $x^1, \ldots, x^d$, as described in Section 2.2. We pose a variational formulation for problem (3.1) in this type of domain as:

Given $f \in L^2_{2, \beta}(G)$, find $u \in V^2_{2, \beta}(G)$ such that

$$(\Delta u, \Delta v)_{L^2_{2, \beta}(G)} = -(f, \Delta v)_{L^2_{2, \beta}(G)} \quad \forall v \in V^2_{2, \beta}(G).$$

(3.2)

**Theorem 3.1.** For any $\bar{\beta} = (\beta_1, \ldots, \beta_d) \in \mathbb{R}^d$ such that $1 - \pi/\alpha_j < \beta_j < 1 + \pi/\alpha_j$, $j = 1, \ldots, d$, the variational problem (3.2) has a unique solution $u \in V^2_{2, \beta}(G)$.

**Proof.** Let $a : V^2_{2, \beta}(G) \times V^2_{2, \beta}(G) \to \mathbb{R},$

$$a(u, v) = (\Delta u, \Delta v)_{L^2_{2, \beta}(G)} = \int_G \zeta_0^2 \Delta u \Delta v \, dx + \sum_{j=1}^{d} \int_{K_j} r_j^{2\beta_j} \zeta_j^2 \Delta u \Delta v \, dx,$$

be the bilinear form corresponding to (3.2). Here $\zeta_0, \zeta_1, \ldots, \zeta_d$ are the cut-off functions corresponding to the corners $x^1, \ldots, x^d$, as described in Section 2.2. By applying the Cauchy-Schwarz inequality we obtain

$$|a(u, v)| \leq \|\Delta u\|_{L^2_{2, \beta}(G)} \|\Delta v\|_{L^2_{2, \beta}(G)} \leq C_1 \|u\|_{V^2_{2, \beta}(G)} \|v\|_{V^2_{2, \beta}(G)} \quad \forall u, v \in V^2_{2, \beta}(G),$$
which shows the continuity of $a(\cdot, \cdot)$. From Corollary 2.3 we also have
\[ a(u, u) = \|\Delta u\|_{L^2(\mathcal{G})}^2 \geq C_2 \|u\|^2_{V^2_{2,\gamma}(\mathcal{G})} \quad \forall u \in \hat{V}^2_{2,\gamma}(\mathcal{G}), \]
which shows that $a(\cdot, \cdot)$ is $\hat{V}^2_{2,\gamma}(\mathcal{G})$-coercive. In a similar way, it can be shown that the linear functional
\[ \hat{V}^2_{2,\gamma}(\mathcal{G}) \ni v \mapsto -\int_\mathcal{G} \zeta_0^2 f \Delta v \, dx - \sum_{j=1}^d \int_{\mathcal{K}_j} r^{2\beta_j} \zeta_j^2 f \Delta u \, dx \]
is bounded. The existence and uniqueness of the solution of the variational problem (3.2) follows from the Lax-Milgram lemma \[7\].

3.2. Variational formulation with a global weight. In the variational formulation (3.2), the supports of the weight functions are localized near the corners through the cut-off multipliers. In this section we present an alternative variational formulation where a weight of the $r^{2\beta}$ type extends to the entire domain. This formulation is particularly appealing when the domain has only one reentrant corner; therefore, we will limit our discussion to that case.

Thus, let us consider the Poisson problem (3.1) in a bounded domain $\mathcal{G} \subset \mathbb{R}^2$ with one reentrant corner and introduce the following variational formulation:

Given $f \in L^2(\mathcal{G})$, find $u \in \hat{V}^2_{2,\gamma}(\mathcal{G})$ such that
\[ \int_\mathcal{G} r^{2\beta} \Delta u \Delta v \, dx = -\int_\mathcal{G} r^{2\beta} f \Delta v \, dx \quad \forall v \in \hat{V}^2_{2,\gamma}(\mathcal{G}), \tag{3.3} \]
where $r$ denotes the distance from the reentrant corner and $\beta = (\beta, 0, \ldots, 0) \in \mathbb{R}^d$.

**Lemma 3.2.** Let $\mathcal{G}$ be a bounded domain with one reentrant corner and let $r$ be the distance from the reentrant corner. Then
\[ \|u\|_\beta = \left( \int_\mathcal{G} r^{2\beta} |u|^2 \, dx \right)^{1/2} \tag{3.4} \]
is a norm equivalent to the $L^2_{2,\beta}(\mathcal{G})$-norm, with $\beta = (\beta, 0, \ldots, 0) \in \mathbb{R}^d$.

**Proof.** We will show that there exist constants $C_1, C_2 > 0$ such that
\[ C_1 \|u\|_{L^2_{2,\beta}(\mathcal{G})} \leq \|u\|_\beta \leq C_2 \|u\|_{L^2_{2,\beta}(\mathcal{G})}, \quad \forall u \in L^2_{2,\beta}(\mathcal{G}). \tag{3.5} \]

Let $x^1, \ldots, x^d$ be the corners of $\mathcal{G}$, with $x^1$ the reentrant corner, and $\zeta_j$, $j = 1, \ldots, d$, be the associated cut-off functions as described in Section 2.2. Recall that, with $\beta = (\beta, 0, \ldots, 0)$,
\[ \|u\|^2_{L^2_{2,\beta}(\mathcal{G})} = \|\zeta_0 u\|^2_{L^2(\mathcal{G})} + \sum_{j=1}^d \|\zeta_j u\|^2_{L^2_{2,\beta_j}(\mathcal{K}_j)} \]
\[ = \int_\mathcal{G} |\zeta_0 u|^2 \, dx + \int_{\mathcal{K} \cap \mathcal{U}_1} r^{2\beta_1} |\zeta_1 u|^2 \, dx + \sum_{j=2}^d \int_{\mathcal{K} \cap \mathcal{U}_j} |\zeta_j u|^2 \, dx. \]
Using $\zeta_j(x) \leq 1, \forall x \in U_j$, $j = 1, \ldots, d$, and $\zeta_0 = 0$ in some neighborhood $V_1$ of $x^1$, we obtain
\[
\|u\|^2_{L^2_{2,\beta}(G)} \leq c_0 \int_{\Phi \setminus V_1} |u|^2 \, dx + c_1 \int_{G \cap U_1} r^{2\beta} |u|^2 \, dx + c \sum_{j=2}^d \int_{G \cap U_j} |u|^2 \, dx.
\]
Since $r$ is bounded away from zero on $G \cap U_j$, $j = 2, \ldots, d$, and on $G \setminus V_1$, the last estimate becomes
\[
\|u\|^2_{L^2_{2,\beta}(G)} \leq C_0 \int_{G \setminus V_1} r^{2\beta} |u|^2 \, dx + c_1 \int_{G \cap U_1} r^{2\beta} |u|^2 \, dx + c \sum_{j=2}^d \int_{G \cap U_j} r^{2\beta} |u|^2 \, dx
\]
\[
\leq C \left( \int_{G} r^{2\beta} |u|^2 \, dx + \int_{G \cap U_1} r^{2\beta} |u|^2 \, dx + \sum_{j=2}^d \int_{G \cap U_j} r^{2\beta} |u|^2 \, dx \right)
\]
\[
\leq C_1 \|u\|^2_{\beta},
\]
which proves the first inequality in (3.5).

Next, we prove the second estimate in (3.5). We have
\[
\|u\|^2_{L^2_{2,\beta}(G)} = \int_{G} r^{2\beta} |u|^2 \, dx = \int_{G} r^{2\beta} (\zeta_0 + \zeta_1 + \cdots + \zeta_d)^2 |u|^2 \, dx
\]
\[
\leq c_3 \int_{G} r^{2\beta} (\zeta_0^2 + \zeta_1^2 + \cdots + \zeta_d^2) |u|^2 \, dx
\]
\[
\leq c_4 \int_{G} |\zeta_0 u|^2 \, dx + c_3 \int_{G} r^{2\beta} |\zeta_1 u|^2 \, dx + c_4 \sum_{j=2}^d \int_{G} |\zeta_j u|^2 \, dx,
\]
where we used the fact that $r$ is bounded from above on $G$.

**Theorem 3.3.** If $1 - \pi/\alpha < \beta < 1 + \pi/\alpha$, where $\alpha$ is the interior angle of the reentrant corner, then the variational problem (3.3) has a unique solution $u \in V^2_{2,\beta}(G)$, with $\beta = (\beta, 0, \ldots, 0)$.

**Proof.** By applying Lemma 3.2 and Corollary 2.3 it can be verified that the bilinear form
\[
a : \tilde{V}^2_{2,\beta}(G) \times \tilde{V}^2_{2,\beta}(G) \to \mathbb{R}, \quad a(u, v) = \int_{G} r^{2\beta} \Delta u \Delta v \, dx
\]
and linear functional $\tilde{V}^2_{2,\beta}(G) \ni v \mapsto -\int_{G} r^{2\beta} f \Delta v \, dx$ associated with (3.3) satisfy the conditions of the Lax-Milgram lemma; thus, the assertion of the theorem follows. Details are given in [23].

3.3. **Equivalence of variational formulations.** The traditional $H^1$ variational formulation of the Poisson problem (3.1) reads:

**Given** $f \in H^{-1}(G)$, **find** $u \in H^1_0(G)$ **such that**
\[
\int_{G} \nabla u \cdot \nabla v \, dx = \int_{G} fv \, dx, \quad \forall v \in H^1_0(G).
\]
We wish to show that the unique solution of the variational problem (3.3) in $V_{2,\beta}^2(\mathcal{G})$, for $\beta$ in a given range, coincides with the solution of (3.4). Throughout this section, unless otherwise specified, $\Gamma = (1,0,\ldots,0)$, $-\Gamma = (-1,0,\ldots,0)$, $\bar{\beta} = (\beta,0,\ldots,0)$, $\Gamma - \bar{\beta} = (1-\beta,0,\ldots,0)$. First we state and prove two auxiliary lemmas.

**Lemma 3.4.** Let $\mathcal{G}$ be a bounded domain with one reentrant corner and let $r$ be the distance from the reentrant corner. Then for $\beta \leq 1$

$$\{r^{-2\beta}u : u \in H^1_0(\mathcal{G})\} \subset L_{2,\beta}(\mathcal{G}).$$  \hspace{1cm} (3.7)

*Proof.* Let $u \in H^1_0(\mathcal{G})$. In view of Lemma 3.2 it is sufficient to show that

$$\int_{\mathcal{G}} r^{2\beta} |r^{-2\beta}u|^2 \, dx = \int_{\mathcal{G}} r^{-2\beta} |u|^2 \, dx < \infty.$$  \hspace{1cm} (3.8)

It is shown in [14, Lemma 6.6.1] that the sets $H^1_0(\mathcal{G})$ and $\{u \in V_{2,\beta}^1(\mathcal{G}) : u|_{\partial \mathcal{G}} = 0\}$ coincide. By Lemma 2.1 $V_{2,\beta}^1(\mathcal{G})$ is continuously imbedded in $L_{2,-\beta}(\mathcal{G})$ for $\beta \leq 1$; therefore, $||u||_{L_{2,-\beta}(\mathcal{G})} \leq C ||u||_{H^1_0(\mathcal{G})}$. But $||u||_{L_{2,-\beta}(\mathcal{G})}$ is equivalent to $\int_{\mathcal{G}} r^{-2\beta} |u|^2 \, dx$ whence (3.8) follows. \hfill $\square$

The classical Green’s formula $\int_{\mathcal{G}} v \Delta u \, dx = \int_{\partial \mathcal{G}} v u/\partial n \, da - \int_{\mathcal{G}} \nabla v \cdot \nabla u \, dx$ holds for $u \in C^2(\Omega)$, $v \in C^1(\Omega)$, and $\partial \mathcal{G} \in C^1$. Various weaker versions exist where $u$ and $v$ are moved to Sobolev spaces and the requirement of smoothness of the boundary is relaxed to some extent. See Grisvard [10] for special cases that apply to polygonal domains in $\mathbb{R}^2$ and Kozlov, Maz’ya, and Roßmann [14] for certain types of higher-dimension non-smooth domains. Here we prove a variant of Green’s formula for domains with angular points in $\mathbb{R}^2$ and functions that vanish on the boundary.

**Lemma 3.5.** Let $\mathcal{G} \subset \mathbb{R}^2$ be a domain with one reentrant angle with interior angle $\alpha$. For any $\beta \in \mathbb{R}$ such that $1-\pi/\alpha < \beta < 1+\pi/\alpha$, the following Green’s formula holds:

$$-\int_{\mathcal{G}} v \Delta u \, dx = \int_{\mathcal{G}} \nabla v \cdot \nabla u \, dx \quad \text{for } u \in \hat{V}^2_{2,\beta}(\mathcal{G}), \ v \in \hat{V}^1_{2,1-\beta}. \hspace{1cm} (3.9)$$

*Proof.* We will apply a density argument. Let $\{u_n\}_{n=1}^{\infty}$ be a sequence in $C^\infty_0(\hat{\mathcal{G}} \setminus \{x^1,\ldots,x^d\})$ that converges to $u$ in $\hat{V}^2_{2,\beta}(\mathcal{G})$, and let $\{v_n\}_{n=1}^{\infty}$ be a sequence in $C^\infty_0(\hat{\mathcal{G}})$ that converges to $v$ in $\hat{V}^1_{2,1-\beta}(\mathcal{G})$. We have

$$-\int_{\mathcal{G}} v_n \Delta u_n \, dx = \int_{\mathcal{G}} \nabla u_n \cdot \nabla v_n \, dx \quad \text{for } n \geq 1. \hspace{1cm} (3.10)$$

Let us estimate

$$\left| \int_{\mathcal{G}} v_n \Delta u_n \, dx - \int_{\mathcal{G}} v \Delta u \, dx \right| \leq \int_{\mathcal{G}} |v_n \Delta u_n - v_n \Delta u + v_n \Delta u - v \Delta u| \, dx \leq \int_{\mathcal{G}} r^\beta |\Delta u_n - \Delta u| \, dx + \int_{\mathcal{G}} r^{-\beta} |v_n - v| \, dx + \int_{\mathcal{G}} r^{-\beta} |v_n - v| \, dx \leq \|\Delta u_n - \Delta u\|_{\beta} \|v_n\|_{1-\beta} + \|v_n - v\|_{-\beta} \|\Delta u\|_{\beta}.$$
Next, let us estimate $r$ where $\vec{\beta}$ corner for $\Box$

Finally, passing to the limit in (3.10), we obtain (3.9).

Since $|||\Delta u|||_\beta$ is equivalent to the $V^{2,1}_2(G)$-norm by Corollary 2.3 and Lemma 3.2 $|||\Delta u_n - \Delta u|||_\beta \to 0$ as $n \to \infty$. Moreover, $V^{1,1}_2(G)$ is continuously imbedded in $L_{2,\beta}$; therefore, $|||v_n - v|||_{\beta} \to 0$ as $n \to \infty$ since $\{v_n\}_{n=1}^\infty$ converges to $v$ in $V^{1,1}_2(G)$. Also note that $|||\Delta u|||_\beta$ and $|||v_n|||_\beta$ are bounded. Thus,

$$\int_G v_n \Delta u_n \, dx \to \int_G v \Delta u \, dx \quad \text{as} \quad n \to \infty.$$ 

Next, let us estimate

$$\left| \int_G \nabla u_n \cdot \nabla v_n \, dx - \int_G \nabla u \cdot \nabla v \, dx \right| \leq \int_G |\nabla u_n \cdot \nabla v_n - \nabla u \cdot \nabla v_n + \nabla u \cdot \nabla v_n - \nabla u \cdot \nabla v| \, dx \leq |||\nabla u_n - \nabla u|||_{\beta^{-1}} \cdot |||\nabla v_n - \nabla v|||_{\beta^{-1}} + |||\nabla v_n - \nabla v|||_{\beta^{-1}} \cdot |||\nabla u|||_{\beta^{-1}}.$$ 

Since $V^{2,1}_2(G)$ is continuously imbedded in $V^{1,1}_2(G)$, we obtain from the estimate above

$$\int_G \nabla u_n \cdot \nabla v_n \, dx \to \int_G \nabla u \cdot \nabla v \, dx \quad \text{as} \quad n \to \infty.$$ 

Finally, passing to the limit in (3.10), we obtain (3.9).

**Remark 3.6.** Formula (3.11) can be extended to domains with more than one reentrant corner for $\beta = (\beta_1, \ldots, \beta_d) \in \mathbb{R}^d$ such that $1 - \pi/\alpha_j < \beta_j < 1 + \pi/\alpha_j$, $j = 1, \ldots, d$, and $u \in V^{2,1}_2(G)$, $v \in V^{1,1}_2(G)$, where $\Gamma - \beta = (1 - \beta_1, \ldots, 1 - \beta_d)$.

**Theorem 3.7.** Let $f \in L_{2,\beta}(G)$, $1 - \pi/\alpha < \beta \leq 1$. Then the variational problem (3.3) has a unique solution in $V^{2,1}_2(G)$ that coincides with the solution of the traditional variational problem (3.9).

**Proof.** If $f \in L_{2,\beta}(G)$, $\beta \leq 1$, then for any $\psi \in H^1_0(G)$ we have

$$\int_G f \psi \, dx = \int_G r^{2\beta} f r^{-2\beta} \psi \, dx = \int_G r^{2\beta} f \phi \, dx \leq \left( \int_G r^{2\beta} f^2 \, dx \right)^{1/2} \left( \int_G r^{2\beta} \phi^2 \, dx \right)^{1/2} < \infty,$$

where $r^{-2\beta} \psi = \phi \in L_{2,\beta}(G)$ from Lemma 3.2. Thus $f \in H^{-1}(G)$.

Since $\beta$ satisfies the hypothesis of Theorem 3.3 $1 - \pi/\alpha < \beta < 1 + \pi/\alpha$, the variational problem (3.3) has a unique solution $u \in V^{2,1}_2(G)$ that satisfies

$$\int_G r^{2\beta} \Delta u \Delta v \, dx = - \int_G r^{2\beta} f \Delta v \, dx \quad \forall v \in V^{2,1}_2(G).$$

Corollary 2.3 implies

$$\int_G r^{2\beta} \Delta u \phi \, dx = - \int_G r^{2\beta} f \phi \, dx \quad \forall \phi \in L_{2,\beta}(G).$$
From Lemma 3.4 \( \{ r^{-2\beta} \psi : \psi \in H^1_0(\mathcal{G}) \} \subset L_{2,\beta}(\mathcal{G}) \), so
\[
\int_\mathcal{G} r^{2\beta} \Delta u r^{-2\beta} \psi \, dx = -\int_\mathcal{G} r^{2\beta} \psi \, dx \quad \forall \psi \in H^1_0(\mathcal{G})
\]
or
\[
\int_\mathcal{G} \Delta u \psi \, dx = -\int_\mathcal{G} f \psi \, dx \quad \forall \psi \in H^1_0(\mathcal{G}).
\] (3.11)
Since \( H^1_0(\mathcal{G}) \hookrightarrow \dot{V}^{1}_{2,1-\beta}(\mathcal{G}) \) for \( 1 - \pi/\alpha < \beta \leq 1 \), in view of Lemma 3.5 we may integrate by parts to obtain
\[
\int_\mathcal{G} \nabla u \cdot \nabla \psi \, dx = -\int_\mathcal{G} f \psi \, dx \quad \forall \psi \in H^1_0(\mathcal{G}),
\]
so \( u \) satisfies (3.6) as asserted. \( \square \)

Remark 3.8. The condition \( \beta \leq 1 \) in Theorem 3.7 is essential because it guarantees that the function \( f \in L_{2,\beta}(\mathcal{G}) \) is in \( H^{-1}(\mathcal{G}) \), and hence the traditional \( H^1 \) formulation is well-posed; otherwise the statement of the theorem would make no sense.

4. Variational formulation of the Helmholtz problem in \( V_{2,\beta}^2(\mathcal{G}) \). In this section we consider the boundary value problem

\[
-\Delta u + \lambda u = f \quad \text{in} \ \mathcal{G},
\]
\[
u \quad \text{on} \ \partial \mathcal{G},
\]
where \( \lambda > 0 \) is a constant.

4.1. Variational formulation with local weights. For a bounded domain \( \mathcal{G} \subset \mathbb{R}^2 \) with corners \( x^1, \ldots, x^d \), we introduce the following variational formulation of problem (4.1):

Given \( f \in L_{2,\beta}(\mathcal{G}) \), find \( u \in \dot{V}^2_{2,\beta}(\mathcal{G}) \) such that
\[
(-\Delta u + \lambda u, -\Delta v + \lambda v)_{L_{2,\beta}(\mathcal{G})} = (f, -\Delta v + \lambda v)_{L_{2,\beta}(\mathcal{G})} \quad \forall v \in \dot{V}^2_{2,\beta}(\mathcal{G}).
\] (4.2)

The following lemma is a well-known consequence of the Fredholm alternative for compact operators \([7, 8]\), variants of which are used widely in the literature.

Lemma 4.1. Let \( L : V \to H \) be an isomorphism, where \( V, H \) are Hilbert spaces and \( V \) is compactly imbedded in \( H \). Then, there exists a countable set \( \Lambda \subset \mathbb{R} \) such that if \( \lambda \notin \Lambda \), the operator \( L - \lambda I \) is an isomorphism.

Theorem 4.2. Let \( \mathcal{A}_\lambda : \dot{V}^l_{2,\beta}(\mathcal{G}) \to \dot{V}^{l-2}_{2,\beta}(\mathcal{G}) \), \( \mathcal{A}_\lambda = -\Delta + \lambda I \), where \( l \geq 2 \), \( \beta = (\beta_1, \ldots, \beta_d) \in \mathbb{R}^d \), and \( -\pi/\alpha_j < l - 1 - \beta_j < \pi/\alpha_j \) for \( j = 1, \ldots, d \). Then, there exists a countable set \( \Lambda \subset \mathbb{R} \) such that \( \mathcal{A}_\lambda \) is an isomorphism if \( \lambda \notin \Lambda \).

Proof. Since \( \dot{V}^1_{2,\beta}(\mathcal{G}) \) is compactly imbedded in \( \dot{V}^{1-2}_{2,\beta}(\mathcal{G}) \) (Lemma 2.3), and \( \Delta : \dot{V}^l_{2,\beta}(\mathcal{G}) \to \dot{V}^{l-2}_{2,\beta}(\mathcal{G}) \) is an isomorphism (Corollary 2.3), the assertion follows from Lemma 4.1. \( \square \)

Corollary 4.3. For \( \beta = (\beta_1, \ldots, \beta_d) \in \mathbb{R}^d \) such that \( 1 - \pi/\alpha_j < \beta_j \leq 1 \) for \( j = 1, \ldots, d \), the operator \( \mathcal{A}_\lambda : \dot{V}^2_{2,\beta}(\mathcal{G}) \to \dot{L}^{2,\beta}(\mathcal{G}) \), \( \mathcal{A}_\lambda = -\Delta + \lambda I \), is an isomorphism for any \( \lambda > 0 \).
Proof. Consider the problem
\[
\Delta u = \lambda u \quad \text{in } \mathcal{G},
\]
\[
u = 0 \quad \text{on } \partial \mathcal{G}.
\]
Multiply the equation by \(u\) and integrate over \(\mathcal{G}\) to obtain
\[
\int_{\mathcal{G}} u \Delta u \, dx = \lambda \int_{\mathcal{G}} u^2 \, dx. \tag{4.3}
\]
Since \(\beta_j \leq 1\) for \(j = 1, \ldots, d\), by Lemma 2.1, \(V^2_{2,\beta}(\mathcal{G})\) is continuously imbedded in \(V^1_{2,\tilde{\beta}}(\mathcal{G})\), where \(\tilde{\beta} = (1 - \beta_1, \ldots, 1 - \beta_d)\). Therefore, according to Remark 3.6, we can integrate by parts in (4.3) to obtain
\[
- \int_{\mathcal{G}} |\nabla u|^2 \, dx = \lambda \int_{\mathcal{G}} u^2 \, dx.
\]
This implies that the eigenvalues of the Laplacian, as an operator \(\Delta : V^2_{2,\beta}(\mathcal{G}) \rightarrow L^2_{2,\beta}(\mathcal{G})\), are all negative. Hence the conclusion follows from Theorem 4.2.

Theorem 4.4. If \(1 - \pi/\alpha_j < \beta_j < 1 + \pi/\alpha_j\) for \(j = 1, \ldots, d\), then the variational problem (4.2) has a unique solution \(u \in V^2_{2,\beta}(\mathcal{G}), \tilde{\beta} = (\beta_1, \ldots, \beta_d) \in \mathbb{R}^d\), for any \(\lambda \not\in \Lambda\).

Proof. In view of the isomorphism established in Theorem 4.2, the proof follows from the Lax-Milgram lemma, just as in Theorem 3.1.

Corollary 4.5. If \(1 - \pi/\alpha < \beta_j \leq 1\) for \(j = 1, \ldots, d\), then the variational problem (4.2) has a unique solution \(u \in V^2_{2,\beta}(\mathcal{G}), \tilde{\beta} = (\beta_1, \ldots, \beta_d) \in \mathbb{R}^d\), for any \(\lambda > 0\).

Proof. Follows immediately from Theorem 4.4 and Corollary 4.3.

4.2. Variational formulation with a global weight. Our weak formulation for problem (4.1) in a bounded domain with one reentrant corner is:

Given \(f \in L^2_{2,\beta}(\mathcal{G})\), find \(u \in V^2_{2,\beta}(\mathcal{G})\) such that
\[
\int_{\mathcal{G}} r^{2\beta} (-\Delta u + \lambda u)(-\Delta v + \lambda v) \, dx = \int_{\mathcal{G}} r^{2\tilde{\beta}} (-\Delta v + \lambda v) f \, dx \quad \forall v \in V^2_{2,\beta}(\mathcal{G}), \tag{4.4}
\]
where \(r\) denotes the distance from the reentrant corner and \(\tilde{\beta} = (\beta, 0, \ldots, 0) \in \mathbb{R}^d\).

Theorem 4.6. If \(1 - \pi/\alpha < \beta \leq 1\), where \(\alpha\) is the interior angle of the reentrant corner, then the variational problem (4.1) has a unique solution \(u \in V^2_{2,\beta}(\mathcal{G})\), with \(\tilde{\beta} = (\beta, 0, \ldots, 0)\).

Proof. As before, we apply the Lax-Milgram lemma. The bilinear form corresponding to (4.4) is defined as
\[
a : V^2_{2,\beta}(\mathcal{G}) \times V^2_{2,\beta}(\mathcal{G}) \rightarrow \mathbb{R}, \quad a(u, v) = \int_{\mathcal{G}} r^{2\tilde{\beta}} (-\Delta u + \lambda u)(-\Delta v + \lambda v) \, dx.
\]
The bilinear form is continuous because for any $u, v \in \tilde{V}^2_{2,\beta}(G)$ we have

\[
|a(u, v)| \leq \|u - \Delta u + \lambda u\|_\beta \|v - \Delta v + \lambda v\|_\beta \\
\leq C\|u - \Delta u + \lambda u\|_{L_2(G)} \|v - \Delta v + \lambda v\|_{L_2(G)} \leq C\|u\|_{V^2_{2,\beta}(G)} \|v\|_{V^2_{2,\beta}(G)},
\]

where we used Lemma 3.2 and Corollary 4.3. To prove the coercivity of the bilinear form, we estimate

\[
a(u, u) = \|u - \Delta u + \lambda u\|_\beta^2 \geq C_1 \|u - \Delta u + \lambda u\|_{L_2(G)}^2 \geq C_2 \|u\|_{V^2_{2,\beta}(G)}^2 \forall u \in \tilde{V}^2_{2,\beta}(G),
\]

where again we used Lemma 3.2 and Corollary 4.3. Since the linear functional $v \mapsto \int_G r^{2\beta}(-\Delta v + \lambda v)f \, dx$ is bounded on $\tilde{V}^2_{2,\beta}(G)$, the existence and uniqueness of solution to (4.4) follow.

4.3. Equivalence of variational formulations. The traditional $H^1$ formulation of problem (4.4) reads:

Given $f \in H^{-1}(G)$, find $u \in H^1_0(G)$ such that

\[
\int_G \nabla u \cdot \nabla v \, dx + \lambda \int_G uv \, dx = \int_G fv \quad \forall v \in H^1_0(G).
\]

(4.6)

THEOREM 4.7. Let $f \in L^2_{2,\beta}(G)$, $1 - \pi/\alpha < \beta \leq 1$, and $\lambda > 0$. Then the unique solution of the variational problem (4.4) in $\tilde{V}^2_{2,\beta}(G)$ coincides with the solution of the variational problem (4.6).

Proof. Let $u \in \tilde{V}^2_{2,\beta}(G)$ be the unique solution of the variational problem (4.4). Then, $u$ satisfies

\[
\int_G r^{2\beta}(-\Delta u + \lambda u)(-\Delta v + \lambda v) \, dx = \int_G r^{2\beta}(-\Delta v + \lambda v)f \, dx \quad \forall v \in \tilde{V}^2_{2,\beta}(G).
\]

Corollary 4.3 implies

\[
\int_G r^{2\beta}(-\Delta u + \lambda u)\psi \, dx = \int_G r^{2\beta}f \psi \, dx \quad \forall \psi \in L^2_{2,\beta}(G).
\]

From Lemma 3.4 $\{r^{-2\beta} \psi : \psi \in H^1_0(G)\} \subset L^2_{2,\beta}(G)$, so

\[
\int_G r^{2\beta}(-\Delta u + \lambda u)r^{-2\beta} \psi \, dx = \int_G r^{2\beta}fr^{-2\beta} \psi \, dx \quad \forall \psi \in H^1_0(G);
\]

that is

\[
\int_G (-\Delta u + \lambda u)\psi \, dx = \int_G f \psi \, dx \quad \forall \psi \in H^1_0(G).
\]

By Lemma 3.5 since $H^1_0(G) \hookrightarrow \dot{V}^1_{2,1-\beta}(G)$ for $1 - \pi/\alpha < \beta \leq 1$, we can integrate by parts to obtain

\[
\int_G \nabla u \cdot \nabla \psi \, dx + \lambda \int_G u\psi \, dx = \int_G f \psi \, dx \quad \forall \psi \in H^1_0(G),
\]

which shows that $u$ is the solution of the problem (4.6).

\[\square\]
5. Numerical scheme for the Navier-Stokes equations in weighted Sobolev spaces. We consider the Navier-Stokes equations in a bounded domain $G \subset \mathbb{R}^2$, with no-slip boundary conditions

\begin{align*}
\mathbf{u}_t + (\nabla \mathbf{u}) \mathbf{u} + \nabla p &= \nu \Delta \mathbf{u} + \mathbf{f} & \text{in} & \ G \times (0, T], \\
\text{div} \mathbf{u} &= 0 & \text{in} & \ G \times (0, T], \\
\mathbf{u} &= 0 & \text{on} & \ \partial G \times (0, T], \\
\mathbf{u} &= \mathbf{u}_0 & \text{at} & \ t = 0,
\end{align*}

(5.1)

where $\mathbf{u}$ is the fluid velocity, $p$ is the pressure, $\nu$ is the kinematic viscosity, and $\mathbf{f}$ is an external force.

In [19], Liu, Liu, and Pego have proposed a numerical scheme based on a time-discretization implicit in viscosity and explicit in pressure and convection terms that works as follows:

Given an approximation $\mathbf{u}^n \in [H^2(G) \cap H^1_0(G)]^2$ to the velocity at the $n$th time step, determine $p^n \in H^1(G)$ from a weak-form Poisson equation

$$
\langle \nabla p^n, \nabla \phi \rangle = \langle f^n - (\nabla \mathbf{u}^n) \mathbf{u}^n + \nu \Delta \mathbf{u}^n - \nu \nabla \text{div} \mathbf{u}^n, \nabla \phi \rangle \quad \forall \phi \in H^1(G),
$$

(5.2)

then determine $\mathbf{u}^{n+1} \in [H^2(G) \cap H^1_0(G)]^2$ from the Helmholtz problem

$$
\frac{\mathbf{u}^{n+1} - \mathbf{u}^n}{k} - \nu \Delta \mathbf{u}^{n+1} = f^n - (\nabla \mathbf{u}^n) \mathbf{u}^n - \nabla p^n, \\
\mathbf{u}^{n+1}|_{\partial G} = 0.
$$

(5.3)

Here $\langle \cdot, \cdot \rangle$ denotes the inner product in $L_2$ and $k$ is the time step. The weak form of the latter equation is:

$$
\left\langle -\Delta \mathbf{u}^{n+1} + \frac{1}{\nu k} \mathbf{u}^{n+1}, \Delta \Psi \right\rangle = \left\langle \frac{1}{\nu k} \mathbf{u}^n + \frac{1}{\nu} (f^n - (\nabla \mathbf{u}^n) \mathbf{u}^n + \nabla p^n), \Delta \Psi \right\rangle, \\
\forall \Psi \in [H^2(G) \cap H^1_0(G)]^2.
$$

(5.4)

It is shown in [19] that if the boundary is $C^3$, then the velocity iterates converge in $H^2$. Moreover, the corresponding fully discrete finite element scheme, with $C^1$ elements for velocity and $C^0$ elements for pressure, is unconditionally stable and does not require any compatibility conditions between the finite element spaces for the velocity and pressure.

The condition on the smoothness of the boundary may be relaxed somewhat. Kellogg and Osborn [11] have shown that in convex polygonal domains (see Dauge [5] for convex polyhedra) the velocity field corresponding to the Navier-Stokes equations is in $H^2$. We have applied the numerical scheme (5.2)–(5.3) to several problems on convex polygons and obtained the expected solutions for moderate Reynolds numbers. In non-convex polygons, however, the velocity develops singularities at reentrant corners and no longer is in $H^2$; therefore, equation (5.4) ceases to make sense. For domains of this type we reformulate the scheme (5.2)–(5.3) in weighted Sobolev spaces, along the ideas described in Section 4. Specifically, we propose:
Given an approximation \( u^n \in [V_{2,\beta}(\mathcal{G})]^2 \) to the velocity at the \( n \)th time step, determine \( p^n \in V_{1,\beta}(\mathcal{G}) \) from

\[
(\nabla p^n, \nabla \phi)_{L^2(\mathcal{G})} = (f^n - (\nabla u^n)u^n + \nu \Delta u^n - \nu \nabla \text{div} u^n, \nabla \phi)_{L^2(\mathcal{G})} \quad \forall \phi \in V_{1,\beta}(\mathcal{G}),
\]

then determine \( u^{n+1} \in [V_{2,\beta}(\mathcal{G})]^2 \) from

\[
(-\Delta u^{n+1} + \lambda u^{n+1}, -\Delta \Psi + \lambda \Psi)_{L^2(\mathcal{G})} = (\lambda \nu^n + \lambda k(f^n - (\nabla u^n)u^n - \nabla p^n), -\Delta \Psi + \lambda \Psi)_{L^2(\mathcal{G})}
\]

\[\forall \Psi \in [V_{2,\beta}(\mathcal{G})]^2, \quad (5.6)\]

where \( \lambda = 1/\nu k \).

Osborn [21] has shown that the singularity of the velocity field near a reentrant corner with interior angle \( \alpha \) is related to the roots of the equations \( \sinh^2 z\alpha - z^2 \sin^2 \alpha = 0 \) in the complex plane. In particular, when \( \alpha = 3\pi/2 \), the velocity is \( O(r^\mu) \), where \( \mu \approx 0.5444837368 \). In the numerical simulations presented in Section 6.3 we use \( \beta = (1, 0, \ldots, 0) \), which falls within the range stipulated in Theorem 4.6.

The well-posedness of the variational problems in (5.5)–(5.6) follows from the results in Sections 3 and 4. No proof of convergence of the iterative scheme (5.5)–(5.6) is available at this time but numerical experiments (see Section 6) indicate that the proposed scheme produces the expected solution.

6. Numerical experiments. We have made extensive numerical studies of the problems in Sections 3–5 using a software that we have developed for this purpose. The software, documented in a forthcoming book [22], implements a \( C^1 \)-compatible finite element scheme over an unstructured triangular mesh in arbitrary polygonal domains. The basis elements consist of fifth-degree Argyris polynomials [3]. In the following subsections we will describe numerical results obtained for several test problems.

6.1. The Poisson problem in an L-shaped domain. Consider the problem

\[
-\Delta u = f \quad \text{in} \ G,
\]

\[
u \quad u = 0 \quad \text{on} \ \partial G,
\]

in the L-shaped domain \( G = (-1, 1)^2 \setminus [0, 1] \times [-1, 0] \). We choose

\[
f = \frac{4}{3} r^{2/3} \left[ (10 - 4r^2) \sin \frac{2}{3} \theta - r^2 \sin \frac{10}{3} \theta \right],
\]

which corresponds to the exact solution

\[
u = 2(1 - r_1^2)(1 - r_2^2) r^{2/3} \sin \frac{2}{3} \theta,
\]

where \( r, \theta \) are the polar coordinates associated with the Cartesian coordinates \( x_1, x_2 \). Here and in the sequel \( A \) denotes the area of the largest element in an unstructured
triangular mesh, $h = \sqrt{A}$, and $u_h$ denotes the corresponding finite element solution. We let $\mathbf{1} = (1,0,\ldots,0) \in \mathbb{R}^6$ and recall the notations:

\[
\|u - u_h\|_{L^2} = \left( \int_G r^2 |u - u_h|^2 \, dx \right)^{1/2},
\]
\[
\|u - u_h\|_{V^2} = \left( \int_G (r^2 |\nabla u - \nabla u_h|^2 + |\nabla u - \nabla u_h|^2 + r^{-2} |u - u_h|^2) \, dx \right)^{1/2},
\]
\[
\|u - u_h\|_{a,\mathbf{1}} = \left( \int_G r^2 |\Delta u - \Delta u_h|^2 \, dx \right)^{1/2}.
\]

Figure 1 shows the sequence of uniform meshes used in computations. In Figure 2 we plot the error in various norms as functions of $h$ in a log-log plot. The convergence of the finite element approximations is proved in [23]. Optimal rates of convergence on graded (non-uniform) meshes are derived in [24].

It can be seen in Figure 2 that the experimental rate of convergence in the $V^2_{2,\mathbf{1}}$ norm is approximately $2/3$. The same rate of convergence is observed for the $H^1$ norm. This result is consistent with the rate of convergence expected for the traditional $H^1$ formulation, when uniform meshes are used. In [24] we derive error estimates in the $V^2_{2,\mathbf{1}}$ norm and design graded meshes that yield optimal convergence rates.

6.2. Helmholtz equation in an L-shaped domain. We consider the boundary value problem

\[
-\Delta u + \lambda u = f \quad \text{in } \mathcal{G},
\]
\[
u = 0 \quad \text{on } \partial \mathcal{G},
\]
with $\lambda > 0$ constant, in the L-shaped domain $\mathcal{G} = (-1,1)^2 \setminus [0,1] \times [-1,0]$. We choose $f$ such that the exact solution of the problem is given by (6.2).

We have performed numerical studies for various values of the parameter $\lambda$. We summarize here the results obtained for $\lambda = 3$, noting that similar results were obtained for other values of $\lambda$. For this problem $\|u\|_{a,\mathbf{1}} = \left( \int_G r^2 |\Delta u - \lambda u|^2 \, dx \right)^{1/2}$. The meshes used in our computations are the same as in the previous section and are plotted in Figure 1. Figure 3 shows the errors as functions of $h$ in a log-log plot. The experimental convergence rates observed are similarly obtained for the Poisson problem.
6.3. Navier-Stokes equations: Backstep flow. In this section we solve a classical benchmark problem in fluid dynamics, the backstep problem, using the scheme described in (5.5)–(5.6).

The diagram in Figure 4 depicts a flow region where the fluid enters from the left, flows over a step, and leaves to the right. We prescribe parabolic velocity profiles at the inlet and outlet, and zero velocities on the rest of the boundary. Specifically, in the simulations presented here, we use \(f = 0\), \(\nu = 1\), and
\[
\begin{align*}
  u_1 &= 128x_2(1 - x_2), \quad u_2 = 0 \quad \text{at } x_1 = -1, \\
  u_1 &= 16(1 + x_2)(1 - x_2), \quad u_2 = 0 \quad \text{at } x_1 = 3.
\end{align*}
\]

This corresponds to a Reynolds number \(Re \approx 43\), where \(Re = 2HU_{\text{avg}}/\nu\). Here \(H = 1\) is the height of the step and \(U_{\text{avg}}\) is the average velocity at the inlet.

No exact solution is available for flow over a backstep; therefore, we compare our solution against that produced by the commercial software package Comsol. In Figures 5(a), (c), (e), and (g), we show the graphs of the \(x\) and \(y\) components of the velocity, pressure, and divergence obtained with our weighted \(H^2\) solver, and in Figures 5(b), (d), (f), and (h), we show the corresponding graphs produced by Comsol’s \(H^1\) solver. These results were obtained by solving the time-dependent Navier-Stokes equations until steady-state was reached.
Fig. 3. Log-log plot of the error in various norms for the Helmholtz problem, $\lambda = 3$, giving experimental rates of convergence as respective slopes. A line with slope $2/3$ is displayed for comparison.

Fig. 4. Streamlines in the backstep flow.

We view the numerical results presented in this section as experiments illustrating the viability of our variational formulations, rather than a proof of superiority of our approach to those of others.

7. Acknowledgments. This article is partially based on the doctoral dissertation [23] of the first author at the University of Maryland, Baltimore County. The author gratefully acknowledges the financial support from the University of Maryland, Baltimore County during the course of her studies.
