THE ORDER DUAL OF THE SPACE OF RADON MEASURES{(1)}

BY

JOHN MACK

Introduction. In [14] and [15] S. Kaplan studied the second dual of the Banach lattice of all continuous real-valued functions on a compact space. Then in [16] he initiated a study of the second dual of the lattice of continuous functions with compact support on a locally compact space. It is the purpose of this paper to continue the study of the locally compact case.

For a locally compact space $X$, let $L_k$ denote the vector lattice of Radon measures on $X$. In §2 the basic properties of $L_k$ are established. In §3 we devote our attention to the proof of the following theorem: Every purely nonatomic measure defined on a $\sigma$-compact space can be extended to a measure on a countably compact space.

Given a compact subset $K$ of $X$, let $L(K)$ denote the set of Radon measures on $K$. Then $L(K)$ can be identified with an ideal in $L_k$. The set $\bigcup L(K)$, where the union is taken over all compact subsets of $X$, is the set of all measures with compact support. It appears that the order dual $M$ of $\bigcup L(K)$ is an appropriate object of study as well as the order dual $M_k$ of $L_k$ and the order dual $M_b$ of the space $L_b$ of all finite measures. In particular, $C$ (the set of all continuous real-valued functions on $X$) can be embedded in $M$ while in general this is not possible for either $M_k$ or $M_b$. The spaces $M_k$ and $M_b$ appear as ideals in $M$. Also, $M$ can be characterized as the set of all multiplication operators on $L_k$.

In §5 we consider the question of whether $M_k$ can be identified with a set of continuous functions with compact support. This is the question raised by Kaplan in [16, §§5,7]. After giving an example which shows that in general this is not possible, we state conditions which are sufficient to insure that $M_k$ will be the set of continuous functions with compact support on some locally compact space. In §6 we turn our attention to the duality relations which exist between the ideals in $L_k$ and those in $M$.

It will be assumed that the reader is familiar with Kaplan’s papers, On the second dual of the space of continuous functions [14], [15], [16].

{(1)} This paper is based upon the author’s doctoral dissertation, which was written under the direction of Professor Meyer Jerison. This research was supported in part by the Purdue Research Foundation and the National Science Foundation.

Presented to the Society, August 29, 1963; received by the editors May 6, 1963.
1. Preliminaries. In this section $E$ denotes a vector lattice whose positive cone is $E_+$. For elements $a \in E$, $b \in E$, the set \{ $x \in E : a \leq x \leq b$ \} will be called an interval. A subset $A$ of $E$ is bounded if $A$ is contained in an interval. A linear subspace $I$ is an ideal if for $x \in I$, $y \in E$, $|y| \leq |x|$ implies that $y \in I$. If $x$ belongs to an ideal $I$, then $0 \leq x^+ \leq |x|$ implies that $x^+ \in I$. Hence an ideal is a subvector lattice. The ideal generated by a subset $A$ of $E$ is the intersection of all ideals containing $A$.

For a net \{$x_\alpha$\} in $E$ and an element $x \in E$, we define $x_\alpha \downarrow x$ to mean $x = \bigwedge_\alpha x_\alpha$ and that $x_\alpha \leq x_\beta$ whenever $\alpha > \beta$. Similarly $x_\alpha \uparrow x$ means $x = \bigvee_\alpha x_\alpha$ and that $x_\alpha \geq x_\beta$ whenever $\alpha > \beta$. The net \{$x_\alpha$\} converges to $x$ if there exists a net \{$y_\alpha$\} in $E$ such that $|x - x_\alpha| \leq y_\alpha$ and $y_\alpha \downarrow 0$. We write $\lim x_\alpha = x$ whenever \{$x_\alpha$\} converges to $x$. Since $||x| - |x_\alpha|| \leq |x - x_\alpha|$, it follows that $\lim |x_\alpha| = |x|$ provided $\lim x_\alpha = x$. A subset $A$ of $E$ is closed (σ-closed) if it contains the limit of each convergent net (convergent sequence) in $A$. The closure (σ-closure) of $A$ is the intersection of all closed (σ-closed) sets containing $A$. The closure of $A$ will be denoted by $\bar{A}$ and the σ-closure by $\sigma A$. The closed ideal generated by $A$ is defined to be the intersection of all closed ideals containing $A$. Two elements $x$ and $y$ in $E$ are disjoint if $|x| \wedge |y| = 0$. For $A \subseteq E$, define $A' = \{ x \in E : |x| \wedge |a| = 0$ for each $a \in A \}$. Then $A'$ is a closed ideal in $E$. If $A$ and $B$ are subsets of $E$ with $A \subseteq B$, then $A$ is said to be dense in $B$ provided each point of $B$ is the limit of a net in $A$.

**Theorem 1.1** (Riesz). Let $E$ be a complete vector lattice. For any subset $A$ of $E$, $(A')'$ is the closed ideal generated by $A$, and $E = A' \oplus (A')'$. For a proof of Theorem 1.1 see [3, Théorème 1, p. 25].

**Remark 1.** A set may fail to be dense in its closure. However, an ideal is dense in its closure. In fact, $(I)_+$ may be obtained from $I_+$ by adjoining the suprema of subsets of $I_+$. Whence it follows that the closed ideal generated by a set $A$ is the closure of the ideal generated by $A$.

**Remark 2.** We shall use the unmodified terms: dense, closure, convergent, etc. in the sense defined above. Whenever we wish to use these terms in the usual topological sense with respect to a topology $\tau$, we shall then modify them with $\tau$, e.g., $\tau$-dense, $\tau$-closure, $\tau$-convergent, etc.

**Remark 3.** If $E$ is complete, then $\lim x_\alpha = x$ is equivalent to the statement that $\{x_\alpha : \alpha > \beta\}$ is bounded for some index $\beta$ and $x = \bigvee_\beta \bigwedge_{\alpha \geq \beta} x_\alpha = \bigwedge_{\beta} \bigvee_{\alpha \geq \beta} x_\alpha$.

Let $E$ and $F$ be vector lattices. A mapping of $E$ into $F$ is bounded if it transforms bounded sets into bounded sets. A linear mapping is said to be positive if it maps $E_+$ into $F_+$. If $F$ is a complete vector lattice, then a linear mapping of $E$ into $F$ is bounded if and only if it is the difference of two positive linear mappings. In addition, the set of all bounded linear mappings of $E$ into a complete vector lattice $F$ is a complete vector lattice. The proofs of these statements can be patterned.
after those for linear functionals [3, Théorème 1, p. 35]. A mapping \( \phi \) of \( E \) into \( F \) is \textit{continuous} if for each convergent net \( \{x_a\} \) in \( E \), the net \( \{\phi(x_a)\} \) converges in \( F \) and \( \phi(\lim x_a) = \lim \phi(x_a) \). It is easy to show that when \( \phi \) is a bounded linear mapping of \( E \) into a complete vector lattice \( F \), \( \phi \) is continuous if \( \lim |\phi|(x_a) = 0 \) for each net in \( E \) such that \( x_a \downarrow 0 \).

**Proposition 1.2.** If \( \phi \) is a continuous mapping of \( E \) into \( F \), then \( \phi(\bar{A}) \subseteq \overline{\phi(A)} \) for each subset of \( E \).

Since the vector lattice operations are continuous mappings of \( E \times E \) into \( E \) we have:

**Proposition 1.3.** The closure of a subvector lattice is a subvector lattice.

A linear mapping of \( E \) into \( F \) is a \textit{lattice homomorphism} if it preserves the lattice operations. A one-to-one lattice homomorphism is called a \textit{lattice isomorphism}.

**Proposition 1.4.** Let \( \phi \) be a linear transformation of \( E \) into \( F \) which maps \( E_+ \) onto \( F_+ \). If \( \phi \) is one-to-one on \( E_+ \) and if its inverse maps \( F_+ \) into \( E_+ \), then \( \phi \) is a lattice isomorphism of \( E \) onto \( F \).

In this paper we shall be mainly concerned with linear functionals. The set of all bounded linear functionals defined on the vector lattice \( E \) will be denoted by \( \Omega(E) \) while \( \tilde{\Omega}(E) \) will signify the set of elements of \( \Omega(E) \) which are continuous. If the set of positive linear functionals is taken as the positive cone, then \( \Omega(E) \) and \( \tilde{\Omega}(E) \) are complete vector lattices and \( \tilde{\Omega}(E) \) is a closed ideal in \( \Omega(E) \) [15, (3.1)]. An element \( \phi \) of \( \tilde{\Omega}(E) \) is also an element of \( \Omega(E) \) if and only if \( \lim |\phi|(x_a) = 0 \) for each net in \( E \) such that \( x_a \downarrow 0 \).

Given \( a \in E_+ \), define \( \| \phi \|_a = |\phi|(a) \) for each \( \phi \in \Omega(E) \). Then \( \| \phi \|_a \) is a pseudo-norm on \( \Omega(E) \). The family of all such pseudonorms defines a locally convex topology on \( \Omega(E) \) which is compatible with the order in \( \Omega(E) \) and with respect to which \( \Omega(E) \) is complete [3, Exercise 9, p. 40]. This topology will be denoted by \( \| w \|_1 \) (\( \Omega(E), \Omega(E) \)) -topology on \( E \) can be defined.

For a subset \( A \) of \( E \), let \( A^\perp \) denote the orthogonal complement of \( A \) in \( \Omega(E) \), i.e., \( A^\perp = \{ \phi \in \Omega(E) : \phi(x) = 0 \ \text{for all} \ x \in A \} \). Similarly, define \( B^\perp = \{ x \in E : \phi(x) = 0 \ \text{for all} \ \phi \in B \} \) for each subset \( B \) of \( \Omega(E) \). The null ideal in \( \Omega(E) \) of a subset \( A \) of \( E \) is the set \( \{ \phi \in \Omega(E) : |\phi|(x) = 0 \ \text{for each} \ x \in A \} \). The null ideal of \( A \) is the largest ideal contained in \( A^\perp \). Furthermore, if \( I \) is the ideal in \( E \) generated by \( A \), then \( I^\perp \) is the null ideal of \( A \). The null ideal in \( E \) of a subset of \( \Omega(E) \) is defined in a similar manner. Some of the properties of null ideals are listed in [15, §§2,3].

2. The spaces \( L_k \) and \( L_p^\ast \). Throughout this paper \( X \) will be a locally compact space. The symbol \( C = C(X) \) will be used to represent the vector lattice of real continuous functions on \( X \). The set of bounded functions in \( C \) will be denoted
by $C_b = C_b(X)$. The set of real continuous functions which vanish at infinity will be denoted by $C_0 = C_0(X)$ while $C_k = C_k(X)$ will be the set of functions in $C$ which have compact support. $C_k$ and $C_0$ appear as lattice ideals in $C$.

Let $L_b = L_b(X)$ be the order dual $\Omega(C_k)$ of $C_k$. Similarly define $L_b = L_b(X) = \Omega(L_b)$. Then $L_b$ is also the Banach space dual of $C_\infty$ [14, (3.8)] while $L_b$ is the space of all Radon measures [3, p. 54]. For $\mu \in L_b$ define $\| \mu \| = \sup \{ |\mu(h)| : h \in C_k, \| h \| \leq 1 \}$ ($\| \mu \|$ is taken to be $\infty$ if the defining set is unbounded). The space $L_b$ consists precisely of those elements of $L_b$ for which $\| \mu \| < \infty$. The elements of $L_b$ will be called finite measures and those in the $\sigma$-closure $\sigma L_b$ of $L_b$ will be called $\sigma$-finite. The spaces $L_b$ and $\sigma L_b$ are dense ideals in $L_b$ [16, (3.5)].

We shall write $C(X), L_b(X)$, etc. only when we wish to emphasize the underlying space $X$. At other times we will write merely $C, L_b$, etc.

**Proposition 2.1.** The mapping $\mu \to \| \mu \|$ is continuous on $L_b$.

**Proof.** Let $\{ \mu_n \}$ converge to $\mu$ in $L_b$. Then there is a net $\{ \lambda_n \}$ in $L_b$ such that $|\mu - \mu_n| \leq \lambda_n$ while $\lambda_n \to 0$. Thus the lim $\| \lambda_n \| = 0$ [16, (3.1)] and lim $\| \mu_n \| = \| \mu \|$. The support of $\mu \in L_b$ is defined to be the intersection of all closed sets $F \subset X$ such that $\mu(f) = 0$ for each $f \in C_k$ which vanishes on $F$. It follows that if $f \in C_k$ fails to vanish on the support of $\mu$, then $|\mu(f)| > 0$ [3, Proposition 9, p. 72]. For each $x \in X$ define $e_x(f) = f(x)$ where $f \in C$. Then $e_x \in L_b, e_x > 0$ and $\| e_x \| = 1$. The support of $e_x$ is $\{ x \}$.

**Proposition 2.2.** Let $\mu \in L_b$. If the support of $\mu$ consists of a single point $x$, then $\mu = re_x$ for some real number $r$.

**Proof.** Let $h \in C_k$ be such that $h(x) = 1$ and then set $r = \mu(h)$. Since $f - [f(x)]h$ vanishes on the support of $\mu$, $\mu(f) = f(x) \mu(h) = re_x(f)$ for each $f \in C_k$. Hence $\mu = re_x$.

Recall that $\tilde{\Omega}(E)$ denotes the set of all bounded continuous linear functionals on the vector lattice $E$.

**Proposition 2.3.** Let $x \in X$. Then $e_x \in \tilde{\Omega}(C_k)$ if and only if $x$ is an isolated point of $X$.

**Proof.** Set $f_x = \bigwedge \{ g : g \in C_k, g(x) = 1 \}$. Clearly $f_x$ exists in $C_k$ and $f_x(y) = 0$ for all $y \in X, y \neq x$. If $e_x \in \tilde{\Omega}(C_k)$, then $f_x(x) = e_x(f_x) = 1$. Thus $x$ is isolated. Conversely, suppose $x$ is an isolated point. Then $[\lim f_x](x) = \lim f_x(x)$ for any convergent net in $C_k$. Hence $e_x \in \tilde{\Omega}(C_k)$.

**Proposition 2.4.** The following are equivalent:

(i) $L_b = \tilde{\Omega}(C_k)$.
(ii) $e_x \in \tilde{\Omega}(C_k)$ for all $x \in X$.
(iii) $X$ is a discrete space.
Proof. Clearly (i) implies (ii). That (ii) and (iii) are equivalent follows from Proposition 2.3. We show that (iii) implies (i). Let $f_\alpha \downarrow 0$ in $C_k$. Since $X$ is discrete $\lim f_\alpha(x) = 0$ for each $x \in X$. Thus $\{f_\alpha\}$ converges uniformly to 0 on each compact set. In addition $f_\alpha$ vanishes outside the support of $f_\beta$ for each $\alpha > \beta$; therefore $\lim \|f_\alpha\| = 0$. Since the elements of $L_k$ are Radon measures $\lim |\mu| (f_\alpha) = 0$ for each $\mu \in L_k$. Thus $L_k = \hat{A}(C_k)$.

Let $(L_k)_0$ denote the closed ideal in $L_k$ generated by $\{\epsilon_x : x \in X\}$.

**Proposition 2.5.** $(L_k)_0$ is the $\|w\|(L_k, C_k)$-closure of the linear subspace of $L_k$ generated by $\{\epsilon_x : x \in X\}$.

**Proof.** Let $I$ be the linear subspace generated by $\{\epsilon_x : x \in X\}$. We shall prove that $I$ is an ideal. It suffices to show that the linear space generated by each $\epsilon_x$ is an ideal [14, (1.2)]. If $\mu \in L_k$, $|\mu| \leq s_{\epsilon_x}$ for some $s$, then the support of $\mu$ is $\{x\}$. Hence $\mu = s_{\epsilon_x}$ [Proposition 2.2]. Thus $I$ is an ideal. Since an ideal in $L_k$ is closed if and only if it is $\|w\|(L_k, C_k)$-closed [14, (11.5)], the $\|w\|(L_k, C_k)$-closure of $I$ is $(L_k)_0$.

Let us identify the element $\sum_i s_{\epsilon_{x_i}}$, $i = 1, 2, \ldots n$, with the function on $X$ defined by $\mu(x_i) = r_i$ and $\mu(x) = 0$ for $x \neq x_i$, $i = 1, 2, \ldots n$. Since $L_k$ is $\|w\|(L_k, C_k)$-complete [3, Exercise 9, p. 40], it follows that $(L_k)_0$ is the $\|w\|(L_k, C_k)$-completion of the linear space generated by $\{\epsilon_x : x \in X\}$. Therefore we have

**Proposition 2.6.** $(L_k)_0$ is lattice isomorphic with the lattice of real-valued functions $\mu$ on $X$ such that $\sum x \in X |\mu(x)| < \infty$ for each compact subset $K$ of $X$. (The order is given by: $\mu \geq 0$ if $\mu(x) \geq 0$ for all $x \in X$.)

Define $(L_k)_1 = (L_k)_0$. Then $L_k = (L_k)_0 \oplus (L_k)_1$. For $\mu \in L_k$, let $\mu_0$ and $\mu_1$ denote the components of $\mu$ in $(L_k)_0$ and $(L_k)_1$ respectively. For $A \subset L_k$ define $A_0 = \{\mu_0 : \mu \in A\}$ and $A_1 = \{\mu_1 : \mu \in A\}$. In particular $(L_k)_0$ and $(L_k)_1$ denote the projections of $L_k$ into $(L_k)_0$ and $(L_k)_1$. We can now state the following:

**Proposition 2.7.** $(L_k)_0$ is isometric and lattice isomorphic with the Banach lattice of real functions $\mu$ on $X$ for which $\sum x \in X |\mu(x)| < \infty$. (The order is given by: $\mu \geq 0$ if $\mu(x) \geq 0$ for all $x \in X$ and the norm by: $\|\mu\| = \sum x \in X |\mu(x)|$.)

The space $(L_k)_0$ consists of the purely atomic Radon measures and $(L_k)_1$ contains the nonatomic Radon measures. The following is an easy consequence of Proposition 2.6.

**Proposition 2.8.** If every atomic measure is finite, then $X$ is countably compact.

The converse of Proposition 2.8 is false. This will be shown in §3.

For $f \in C$ and $\mu \in L_k$ define $\phi' \mu(f) = \mu(f \phi)$, $f \in C_k$. This defines $\phi'$ as a continuous operator on $L_k$ [16, (6.6)]. Observe that $\phi' L_k \subseteq L_k$ for each $\phi \in C_k$. 

License or copyright restrictions may apply to redistribution; see https://www.ams.org/journal-terms-of-use
PROPOSITION 2.9. If \( \mu \in (L_k)_+ \), the mapping \( \phi \to \phi'\mu \) is a lattice homomorphism of \( C \) into \( L_k \).

Proof. Let \( \phi \in C \). It is enough to show that \((\phi'\mu)^+ = (\phi^+)^'\mu \). According to \([16, (8.2)] \) \((\phi^+)^'\mu\) and \((\phi^-)^'\mu\) are disjoint. Thus \((\phi'\mu)^+ = [(\phi^+)^'\mu - (\phi^-)^'\mu]^+ = (\phi^+)^'\mu \) [2, Lemma 2, p. 220].

We now consider measures on subspaces of \( X \).

PROPOSITION 2.10. If \( W \) is a locally compact subspace of \( X \), then \( L_k(X) \cap L_k(W) \) is a closed ideal in \( L_k(X) \).

Proof. Let \( I = \{ f \in C_k(X) : f(x) = 0 \text{ on } W \} \). Then \( C_k(X)/I \) is isomorphic with \( C_k(W^-) \) where \( W^- \) denotes the closure of \( W \) with respect to the topology on \( X \). Thus \( L_k(X) = L_k(W^-) \oplus I \) [16, §2]. Since \( C_k(W) \) can be identified with an ideal in \( C_k(W^-) \), we have \( L_k(W^-) = L_k(W) \cap L_k(W^-) \oplus C_k(W)^+ \). Thus \( L_k(W) \cap L_k(X) = L_k(W) \cap L_k(W^-) \) is a closed ideal in \( L_k(X) \).

COROLLARY 2.11. If \( W \) is a closed subspace of \( X \), then \( L_k(W) \) is a closed ideal in \( L_k(X) \). Furthermore \( L_k(W) \) consists of those elements of \( L_k(X) \) whose support is contained in \( W \).

Let \( \mu \in L_k(X) \). The component of \( \mu \) in \( L_k(W) \cap L_k(X) \) will be called the restriction of \( \mu \) to \( W \).

If \( K \) is a compact subset of \( X \), we shall write \( L(K) \) rather than \( L_k(K) \). Our primary interest will lie with the set \( \bigcup L(K) \) where the union is taken over all of the compact subsets of \( X \). The set \( \bigcup L(K) \) consists of those elements of \( L_k \) whose support is compact.

PROPOSITION 2.12. \( \bigcup L(K) = C_kL_k \).

Proof. Let \( \phi \in C_k \) and \( \mu \in L_k \). Then the support of \( \phi'\mu \) is contained in that of \( \phi \) [3, Proposition 10, p. 73]. Thus \( C_kL_k \subset \bigcup L(K) \). Clearly \( \bigcup L(K) \subset C_kL_k \).

The following is due to S. Kaplan [16, (4.2)]:

PROPOSITION 2.13. The set \( \bigcup L(K) \) is an ideal in \( L_k \) and is dense in \( L_k \).

COROLLARY 2.14. If \( X \) is discrete, then \( L_k = (L_k)_0 \).

Proof. If \( X \) is discrete, then \( \bigcup L(K) \) is the set of measures with finite support. Hence \( \bigcup L(K) \subset (L_k)_0 \). The corollary now follows from Proposition 2.13.

Example. Let \( N^\ast \) be the one-point compactification of \( N \). Then every measure on \( N^\ast \) is atomic. Thus the converse of Corollary 2.14 is false.

3. Extensions of measures. Let \( \mu \in L_k(X) \). We shall say that \( \mu \) is extendable to a locally compact space \( T \) if \( X \) is a topological subspace of \( T \) and \( \mu \) is the restriction to \( X \) of some element of \( L_k(T) \). Any element of \( L_k(T) \) whose restriction to \( X \) is \( \mu \) will be called an extension of \( \mu \).
In this section we shall be concerned primarily with the proof of the following:

**Theorem 3.1.** Let \( \mu \) be a Radon measure on a \( \sigma \)-compact space \( X \). If the atomic part of \( \mu \) is finite, then \( \mu \) can be extended to a locally compact space \( T \) on which every atomic measure is finite. In particular, \( T \) is countably compact.

This theorem was motivated by a question posed by S. Kaplan [16, §3]: If every atomic measure on a space is finite, does it follow that every measure on the space is finite? To answer this question we need only to let \( X \) be the real line, \( \mu \) be the Lebesgue measure and then consider the space \( T \) mentioned in Theorem 3.1. While every atomic measure on \( T \) is finite, the space admits measures which are not finite. In particular, no extension of the Lebesgue measure is finite.

In proving Theorem 3.1 we shall construct a space \( T \) for each \( \mu \in L_k \) and then show that \( T \) has the required properties when the atomic part of \( \mu \) is finite. Let \( \mu \) be an arbitrary element of \( L_k \). Denote by \( A \) the set of \( f \in C_b \) for which \( f \mu \in L_b \); then set \( A^\# = \{ f^\#: f \in A \} \). Here \( f^\# \) denotes the continuous extension of \( f \) to the Stone-Čech compactification \( \beta X \) [8, Theorem 6.5]. Now let \( T \) be the complement in \( \beta X \) of the null set of \( A^\# \), i.e., \( T = \{ p \in \beta X : f^\#(p) \neq 0 \text{ for some } f \in A \} \). Since \( T \) is open in the compact space \( \beta X \), it is locally compact. It follows from the fact that \( C_k(X) \subset A \) that \( X \subset T \subset \beta X \). Thus \( C_k(X) \) and \( C_k(T) \) are isomorphic with \( C(\beta X) \) [8, Theorem 6.7]. For each \( f \in C_k(X) \) we shall identify \( f^\# \) and \( f^\# \mid T \) with \( f \) and use the symbol \( f \) to denote all three functions. We are now in a position to prove the following:

**Lemma 3.2.**

(i) \( A \) is an ideal in \( C_b \).

(ii) \( C_k(T) \subset A \subset C_\infty(T) \).

(iii) \( \mu \) is extendable to \( T \), i.e., \( \mu \in L_k(X) \cap L_k(T) \).

**Proof.**

(i) Since \( \phi \mid ^\# \mid \mu \mid = \mid \phi \mu \mid \) for each \( \phi \in C \) [Proposition 2.9 and 16, (6.6)], \( f \in A, g \in C_b, \mid g \mid \leq \mid f \mid \) implies \( \mid g \mu \mid \leq \mid f \mu \mid \) \( \mu \mid = \mid f \mu \mid \). Thus \( g \in A \).

(ii) It is clear from the manner in which \( T \) was constructed that \( A \subset C_\infty(T) \). Next let \( g \in C_k(T) \) and denote the support of \( g \) by \( K \). The family \( \{ U_f \}_{f \in A} \) where \( U_f = \{ x \in T : f(x) > 1 \} \) forms an open cover for \( K \). Since \( K \) is compact there are finitely many elements \( f_1, f_2, \ldots, f_n \) in \( A \) such that \( \bigwedge^n_{i=1} f_i \) dominates the characteristic function of \( K \). Thus \( \mid g \mid \leq \mid g \mid \bigwedge^n_{i=1} \mid f_i \mid \). Since \( A \) is an ideal, \( g \in A \). Thus \( C_k(T) \subset A \).

(iii) For \( f \in C_k(T) \) define \( \bar{\mu}(f) = \| (f')^+ \mu \| - \| (f')^- \mu \| \). It follows from (ii) and the \( L \)-space property of \( L_b \) [2, p. 256] that \( \bar{\mu} \) is a bounded linear functional on \( C_k(T) \). Thus \( \bar{\mu} \in L_k(T) \). We show that \( \bar{\mu} \) is an extension of \( \mu \). For \( g \in C_k(X) \) let \( \phi \in C_k(X) \) be such that \( g \phi = g \). Then \( \phi(x) = 1 \) on the support of \( g' \mu \). Hence \( \| (g')^+ \mu \| = \| (g')^+ (\phi) \| \) and \( \| (g')^- \mu \| = \| (g')^- (\phi) \| \). Thus \( \bar{\mu}(g) = g' \mu (\phi) = \mu (g \phi) = \mu (g) \) for each \( g \in C_k(X) \).

**Lemma 3.3.** Let \( \lambda \in L_k(T) \). If \( \| \lambda \| = \| \mu \| = 0 \), then \( \lambda \in L_k(T) \).
Proof. Since \( \mu \) and \( | \mu | \) give rise to the same space \( T \) and since \( L_k \) is an ideal, we may assume that \( \lambda \) and \( \mu \) are positive. First we verify the following: (I) If \( \lambda \land \mu = 0 \) and \( g \in C_k \), \( 0 \leq g \leq 1 \) (\( 1(x) = 1 \) for \( x \in T \)) with \( \lambda(g) > 0 \), then for each \( \varepsilon > 0 \) there exists \( f \in C_k \), \( 0 \leq f \leq 1 \) whose support is contained in that of \( g \) such that \( \lambda((2f - 1)^+) \geq (1 - 3\varepsilon)\lambda(g) \) while \( \mu(f) < \varepsilon \). To prove this statement let \( \phi \in (C_k)_+ \) be such that \( g\phi = g \) and choose \( \phi_1 \in C_k \) so that \( 0 \leq \phi_1 \leq \phi \) and \( \mu(\phi_1) + \lambda(\phi - \phi_1) < \min \{ \varepsilon, \varepsilon \lambda(g) \} \). Direct computations will show that \( f = (r \phi \land 1)\phi_1 \) is the required function when \( r = \lambda(\phi) [\varepsilon \lambda(g)]^{-1} \).

Since \( X \) is \( \sigma \)-compact, there is an increasing sequence of open relatively compact sets \( \{ U_n \} \) such that \( X = \bigcup U_n \). Suppose that \( \lambda \land \mu = 0 \) while \( \| \lambda \| = \infty \). By using (I) in the first part of this proof, it can be shown that there exists a sequence \( \{ f_n \} \) in \( C_k(T) \) such that \( 0 \leq f_n \leq 1 \), \( f_n \) vanishes on \( U_n \) and \( \lambda((2f_n - 1)^+) \geq n \) while \( \mu(f_n) \leq 2^{-n} \). Since all but finitely many of the \( f_n \) vanish on each compact set in \( X \), \( f = \bigvee f_n \) exists in \( C_k(X) \). Also, \( f \) is a finite supremum of the \( f_n \phi \) for each \( \phi \in (C_k(X)_+) \). Thus \( f'\mu(\phi) = \mu(f \phi) \leq \sum \mu(f_n \phi) \leq \| \phi \| ; \) whence \( f'\mu \in L_b \) and \( f \in A \). This implies that \( (2f - 1)^+ \in C_k(T) \) [Lemma 3.2, (ii)].

On the other hand \( \lambda((2f - 1)^+) \geq \lambda((2f_n - 1)^+) \geq n \) for each \( n \). This contradiction completes the proof of Lemma 3.3.

Observe that if the atomic part of \( \mu \) is finite, then \( \mu \) and the nonatomic part of \( \mu \) give rise to the same space. If \( \mu \) is purely nonatomic, then it follows from Lemma 3.3 that every atomic measure on \( T \) is finite. The proof of Theorem 3.1 is now complete.

Remark. The finiteness of the atomic part of \( \mu \) is used only in the last paragraph of the proof of Theorem 3.1. Hence Lemmas 3.2 and 3.3 are valid for any \( \mu \in L_k \).

Theorem 3.4. Let \( \mu \) be a Radon measure on a \( \sigma \)-compact space \( X \). Then \( \mu \) can be extended to a countably compact space \( T \) if and only if the atomic part of \( \mu \) (considered as a function on \( X \)) vanishes at infinity.

Proof. Sufficiency. As noted in the proof of Lemma 3.3, \( \mu \) may be taken to be positive. Assume that \( \mu_0 \) vanishes at infinity and let \( T \) be constructed as in the proof of Theorem 3.1. Then \( \mu \in L_k(X) \cap L_k(T) \) [Lemma 3.2]. Observe that \( \mu_0(x) = 0 \) for all \( x \in T - X \). Suppose that \( T \) is not countably compact. Then there is an infinite set \( F \subset T \) which has no limit points in \( T \). Given an increasing sequence \( \{ U_n \} \) of open relatively compact sets in \( X \) such that \( X = \bigcup U_n \), there exists a sequence \( \{ x_n \} \) of distinct points of \( F \) such that \( x_n \notin \overline{U}_n \). Furthermore, since \( \mu_0 \) vanishes at infinity, the sequence can be chosen so that \( \sum \mu_0(x_n) \) converges. Since \( \varepsilon_x \) and \( \mu - [\mu_0(x)]\varepsilon_x \) are disjoint for each \( x \in T \), there exists \( f_n \in C_k(T) \), \( 0 \leq f_n \leq 1 \) such that \( f_n \) vanishes on \( U_n \), \( f_n(x_n) = 1 \) and \( \mu(f_n) < \mu_0(x_n) + 2^{-n} \) (see the proof of (6.8) in [14]). As in the proof of Lemma 3.3, we see that \( f = \bigvee f_n \) exists in \( C_k(X) \) and that \( f \in A \subset C_{\infty}(T) \). Since \( f(x_n) = 1 \) for each \( n \), the sequence \( \{ x_n \} \) is contained in a compact set. This gives a contradiction. Therefore \( T \) is countably compact.
Necessity. Suppose \( \mu \) is extendable to a countably compact space \( T \). For each \( \varepsilon > 0 \), consider the set \( E = \{ x \in T : |\mu_0(x)| \geq \varepsilon \} \). If \( E \) is infinite, then it has a limit point \( x_0 \). Each neighborhood of \( x_0 \) meets \( E \) in an infinite set. Hence the \( |\mu| \)-measure of each neighborhood of \( x_0 \) is infinite. This is impossible since \( T \) is locally compact. Thus the set \( E \) is finite for each \( \varepsilon > 0 \). Therefore \( \mu_0 \) vanishes at infinity.

Example 1. In Theorem 3.4, it is essential that \( X \) be normal. To see this, let \( X \) be the Tychonoff plank [8, §8.20]. Any countably compact, locally compact space containing the plank also contains the one-point compactification of the plank. Thus the finite measures are the only ones that can be extended to a countably compact space. Define \( \mu \in (L_a)_0 \) as follows: \( \mu(\omega, n) = 1/n \), \( \mu(\sigma, \tau) = 0 \) if \( \sigma < \omega_1 \). Then \( \mu = \mu_0 \) vanishes at infinity but it is not extendable to a countably compact space.

Example 2. Let \( X \) be the real line, \( \mu \) be the Lebesgue measure and \( T \) be the corresponding space given by Theorem 3.1. Let \( h_n \in C_0(T) \) be given by \( h_n(x) = 1 \) for \( |x| \leq n \), \( h_n(x) = 0 \) for \( |x| \geq n + 1 \) or \( x \in T - X \), and by straight line segments elsewhere. It is not difficult to show that if \( \lambda \in L_a(X) \), then \( \lambda \) is also in \( L_a(T) \) only if the sequence \( \{ n^{-1} \lambda(h_n) \} \) is bounded. Then, in view of Lemma 3.3, this sequence is bounded for each \( \lambda \in L_a(T) \). Observe that \( \lim n^{-1} \lambda(h_n) = 0 \) for each \( \lambda \in L_b \) while \( \lim n^{-1} \mu(h_n) = 2 \). These facts will be needed for later examples.

4. The spaces \( M, M_b \) and \( M_k \). In considering Radon measures on locally compact spaces we found in §2 that each of the sets \( \bigcup L(K), L_b, \sigma L_b \) and \( L_k \) is of interest. In this section we shall study the duals of each of these spaces. Define

\[
M = M(X) = \Omega(L(K)), \quad M_b = M_b(X) = \Omega(L_b) \quad \text{and} \quad M_k = M_k(X) = \tilde{\Omega}(L_k).
\]

We take \( \tilde{\Omega}(L_k) \) for \( M_k \) rather than \( \Omega(L_k) \) since \( \Omega(L_k) \) is not in general a subset of \( M \) and since the elements of \( \Omega(L_k) \) which are not in \( \tilde{\Omega}(L_k) \) are only remotely connected to the space \( C_k \) (the closure of \( C_k \) in \( \Omega(L_k) \) is \( \tilde{\Omega}(L_k) \) \[15, (3.10)\]). The various relations existing among \( M_k, \Omega(\sigma L_b) \) and \( \Omega(L_k) \) will be discussed at the end of this section.

Observe that for compact spaces \( M = M_b = M_k \). Let \( K \) be a compact subset of \( X \). Since \( L(K) \) is a closed ideal in \( \bigcup_{\mu \in K} L(K) \), \( M = \Omega(L(K)) \oplus L(K)^\perp \) \[16, (2.4)\]. Therefore \( M(K) = \Omega(L(K)) \) is a closed ideal in \( M \), and \( \bigcup M(K) \), where the union is taken over all compact subsets \( K \) of \( X \), is a subspace of \( M \).

Proposition 4.1. (i) \( M = \tilde{\Omega}(\bigcup L(K)) \).
(ii) \( M_b = \tilde{\Omega}(L_b) \).
(iii) \( M_k = \tilde{\Omega}(\sigma L_b) \).
(iv) \( \bigcup M(K) \subset M_k \subset M_b \subset M \). Furthermore, each set is a dense ideal in \( M \).

Proof. (i) Let \( \mu_x \downarrow 0 \) in \( \bigcup L(K) \). We must show that \( \lim |f| (\mu_x) = 0 \) for each \( f \in M \). We may assume that \( \{ u_x \} \) has an initial element \( \mu_\beta \). If \( K \) is the support of \( \mu_\beta \), then \( \{ u_x \} \) is contained in \( L(K) \). Since \( M = M(K) \oplus L(K)^\perp \), it suffices to show
that \( \lim |f| (\mu_a) = 0 \) for each \( f \in M(K) \). This follows from the relation \( M(K) = \hat{\Omega}(L(K)) \) [15, (4.1)].

For proofs of (ii) and (iii) see [16, (3.1) and (4.5)]. Consider (iv). Since \( \bigcup L(K) \) is dense in \( L_b \), it follows from [16, (2.8)] that \( \bigcup L(K) = \hat{\Omega}(L_b) \) is a dense ideal in \( M = \hat{\Omega}(L(K)) \). The remaining parts of (iv) are taken from [16, (4.3) and (3.6)].

We shall find the concept of multiplication operator a useful tool in characterizing the space \( M \). A bounded operator on a vector lattice \( E \) is called a multiplication operator if each closed ideal in \( E \) is invariant with respect to the operator. The multiplication operators on a complete vector lattice constitute a closed ideal in the vector lattice of all bounded operators on \( E \) [16, §6]. The multiplication operators also form a commutative ring.

**Proposition 4.2.** Each multiplication operator on \( L_k \) is continuous.

**Proof.** Since \( L_k \) is a complete vector lattice, each bounded operator on \( L_k \) is a difference of positive operators. Thus we can restrict our attention to positive operators. Let \( T \) be a positive multiplication operator and let \( \mu_a \downarrow 0 \) in \( L_k \). We must show that \( \mu = \wedge T \mu_a = 0 \). Suppose \( \mu > 0 \). Since \( \bigcup L(K) \) is dense in \( L_k \), there exists a compact \( K \subset X \) such that the component \( \lambda \) of \( \mu \) in \( L(K) \) is nonzero. Let \( \lambda_a \) be the component of \( \mu_a \) in \( L(K) \). Then \( \lambda_a \downarrow 0 \). Since \( T \) is a multiplication operator \( T \lambda_a \) is the component of \( T \mu_a \) in the closed ideal \( L(K) \). Thus \( \lambda = \wedge T \lambda_a \).

Now \( L(K) \) is a Banach lattice; hence \( T \) is norm bounded on \( L(K) \). (Cf. [2, Theorem 10, p. 248].) It follows from Proposition 2.1 that \( \lim \| T \lambda_a \| = 0 \). This implies that \( \lambda = 0 \) [14, (3.4)]. This is a contradiction.

For each multiplication operator \( T \) on \( L_k \) and each \( \mu \in L_k \) such that \( T \mu \in L_b \), define \( T^\ast(\mu) = \| (T \mu)^+ \| - \| (T \mu)^- \| \). Since \( L_b \) is an abstract \( L \)-space, \( T^\ast \) is a bounded linear functional on the ideal \( I = \{ \mu: \mu \in L_k, T \mu \in L_b \} \). The mapping \( \mu \mapsto T^\ast(\mu) \) is a composition of the continuous mappings: \( \mu \mapsto T \mu, \lambda \mapsto \| \lambda \| \) and the lattice operations; hence \( T^\ast \) is a continuous linear functional on \( I \). Now \( L(K) \) is a closed ideal; hence \( TL(K) \subset L(K) \) and \( T \cup L(K) \subset \bigcup L(K) \subset L_b \). Thus \( \bigcup L(K) \) is a dense ideal in \( I \). Whence \( T^\ast \in \hat{\Omega}(\bigcup L(K)) = M \) [16, (2.7)].

Also, observe that if \( T \geq 0 \), then \( T = 0 \) if and only if \( T^\ast = 0 \).

Next we consider the inverse of \( T \to T^\ast \). For \( f \in M \) and \( \mu \in L_k \) let \( f^\mu \) denote the element of \( L_k \) defined by \( f^\mu(h) = f(h\mu), h \in C_k \). Then \( f^\mu \) is a bounded linear operator on \( L_k \). Arguing as in [16, (6.2)] it is easy to show that \( f^\mu \) is a continuous operator.

**Proposition 4.3.** (i) For each multiplication operator \( T \) on \( L_k \), \( T^\ast \in M \).

(ii) For each \( f \in M, f^\mu \) is a continuous multiplication operator on \( L_k \).

**Proof.** Part (i) is proved above. To prove (ii) let \( f \in M \) and let \( I \) be a closed ideal in \( L_k \). For \( \mu \in I \cap \bigcup L(K) \) let \( K \) be the support of \( \mu \); then \( h^\mu \in L(K) \) for all \( h \in C_k \) [3, p. 73]. The component of \( f \) in \( M(K) \) is norm bounded; hence there is a number \( r \) such that \( |f(h^\mu)| \leq r \| h^\mu \| \) for all \( h \in C_k \). Since \( \| h^\mu \| \leq \| \mu \| (| h|) \),
it follows that \( |f'\mu| \leq r|\mu| \). This proves that \( f' \) maps \( I \cap \bigcup L(K) \) into \( I \). The operator \( f' \) is continuous and \( I \cap \bigcup L(K) \) is dense in \( I \); hence \( f'I \subseteq I \) [Proposition 1.2].

**Theorem 4.4.** \( M \) is lattice isomorphic with the vector lattice of all multiplication operators on \( L_k \).

**Proof.** We shall show that the isomorphism is given by the mapping \( T \to T' \). This mapping is one-to-one on the set of positive multiplication operators. Clearly, the mapping \( f \to f' \) is order preserving. In view of Proposition 1.4, it now suffices to show \( f \to f' \) is the inverse of \( T \to T' \). For \( f \in M_+ \), \( \mu \in \bigcup L(K) \) we have \( f''(\mu) = \|f'\mu\| \). Since \( f' \) is a multiplication operator the support of \( f'\mu \) is contained in that of \( \mu \). If \( \phi \in (C_k)_+ \) such that \( \phi(x) = 1 \) on the support of \( \mu \), then \( \phi'\mu = \mu \). Also, \( \phi \) has the constant value 1 on the support of \( f'\mu \); hence \( \|f'\mu\| = f'\mu(\phi) \) [14, (4.1)]. Thus \( f''(\mu) = f'\mu(\phi) = f(\phi'\mu) = f(\mu) \) for all \( \mu \in \bigcup L(K) \).

This completes the proof of Theorem 4.4.

**Remark.** For a given \( f \in M \), \( f'' \) is the extension of \( f \) to the ideal \( \{\mu: \mu \in L_k, f'\mu \in L_b\} \). We shall in general identify \( f \) with its extension \( f'' \).

**Theorem 4.5.** (i) \( M_b = \{f: f \in M, f'L_b \subseteq L_b\} \),

(ii) \( M_k = \{f: f \in M, f'L_k \subseteq L_b\} \),

(iii) \( M_k = \{f: f \in M, f'(\sigma L_b) \subseteq L_b\} \).

**Proof.** We shall prove (ii). If \( f \in M_k \), then \( \|f'\mu\| \leq |f|(|\mu|) \) for each \( \mu \in L_k \).

Therefore \( f'L_k \subseteq L_b \). Conversely, if \( f'L_k \subseteq L_b \), then \( f'' \) extends \( f \) to \( L_k \). Whence \( f \in \tilde{\Omega}(L_k) = M_k \). The proof of (i) is similar to that of (ii). Part (iii) follows from (ii) and [16, (4.5)].

For \( f \in M \), \( g \in M \) define \( fg = (f'g')' \) where \( f'g' \) denotes the composition of the operators \( f' \) and \( g' \). Since the composition of multiplication operators is commutative [16, §6], the space \( M \) becomes a commutative ring under the multiplication defined above.

An element \( u \) of a vector lattice is called a weak order unit if \( u \geq 0 \) and \( u \wedge |x| = 0 \) implies \( x = 0 \). In a normed vector lattice an element 1 is called a strong order unit if \( 1 \geq 0 \), \( \|1\| = 1 \) and \( \|x\| \leq 1 \) implies \( |x| \leq 1 \).

If \( \phi \in C \), then \( \phi' \) is a multiplication operator on \( L_k \) [16, (6.6)]. Thus \( \phi'' \) is an element of \( M \) and the mapping: \( \phi \to \phi'' \) is a natural embedding of \( C \) in \( M \). It follows from Theorem 4.5 that under this embedding \( C_k \) is mapped into \( M_b \) and \( C_k \) goes into \( M_k \).

**Proposition 4.6.** The embedding \( \phi \to \phi'' \) of \( C \) in \( M \) preserves the lattice and ring operations in \( C \). Furthermore \( 1''(1(x) = 1 \) for \( x \in X \) \) is the ring identity for \( M \), a strong order unit for \( M_b \), and a weak order unit for \( M \).

**Proof.** Since \( \bigcup L(K) \) can be identified with an ideal in \( \Omega(C) \), it follows from [18, Theorem 7.9] that the lattice operations are preserved. Let \( \phi \in C \), \( \psi \in C \);
then \((\phi \psi)^t = \phi^t \psi^t\) and hence \((\phi \psi)^{ts} = \phi^{ts} \psi^{ts}\). This shows that the ring operations are preserved. Now \(1_t\) is the identity operator on \(L_k\); whence it follows that \(1^{ts}\) is the ring identity of \(M\). Also \(1^{ts}(\mu) = \|\mu^+\| - \|\mu^-\|\) for each \(\mu \in L_k\). If \(\|f\| \leq 1\), \(f \in M_b\), then \(\|f/(\mu)\| \leq \|f\| \|\mu\| \leq \|\mu\| = 1^{ts}(\mu)\) for each \(\mu \in (L_b)_+\). Thus \(\|f\| \leq 1^{ts}\).

To show that \(1^{ts}\) is a weak order unit for \(M\), let \(g \wedge 1^{ts} = 0\), \(g \in M\). For any compact set \(K\), the component \(g_K\) of \(g\) in \(M(K)\) is in \(M_b\). Since \(1^{ts}\) is a strong order unit for \(M_b\), \(g_K \wedge 1^{ts} = 0\) implies that \(g_K = 0\). Hence \(g\) vanishes on \(\bigcup L(K)\), i.e., \(g = 0\).

Henceforth we shall identify \(\phi \in C\) with \(\phi^{ts}\) and consider \(C\) to be a subspace of \(M\).

**Proposition 4.7.**

(i) The closure of \(C_k\) in \(M\) is \(M\) itself.

(ii) \(C_k\) is \(|w|(M, \bigcup L(K))-dense in M\).

**Proof.** According to [15, (3.10)] the closure of \(C_k\) contains \(M_k\). Since \(M_k\) is dense in \(M\), the proof of (i) is complete. Part (ii) follows from the fact that a convergent net in \(M\) also \(|w|(M, \bigcup L(K))-converges to the same limit [14, (11.7)].

**Proposition 4.8.** For each \(\mu \in L_k\), the mapping \(f \rightarrow f^t\mu\) from \(M\) into \(L_k\) is a continuous linear transformation.

**Proof.** The mapping is clearly linear. If \(|f| \leq g\), \(g \in M\), then \(|f^t\mu| \leq |f^t||\mu| \leq g^t||\mu|\); hence the transformation is bounded. Let \(f_x \downarrow 0\) in \(M\). Then \(f_x^t||\mu|\) is directed downward. For any \(h \in (C_k)_+\), \(\wedge f_x^t||\mu|\)(\(h\)) = inf \(f_x^t||\mu|\)(\(h\)) [14, (2.2)] = \inf \(f_x^t||\mu|\)(\(h\)). Thus \(\wedge f_x^t||\mu| = 0\); this shows that the transformation is continuous.

In the remaining part of this section we shall consider the relation between \(M_k = \hat{Q}(L_k)\) and \(\Omega(L_b)\). It follows from [16, (2.4)] that \(\Omega(L_k) = \Omega(\sigma L_b) \oplus \sigma L_\beta\). Also \(\Omega(L_b) = M_k \oplus L_\beta^*\) [16, (3.6)]; hence \(\Omega(L_b) = M_k \oplus \Omega(\sigma L_b) \cap L_\beta^* \oplus \sigma L_\beta^*\). Since \(M_k = \hat{Q}(\sigma L_b)\), this can be written as \(\Omega(L_k) = \hat{Q}(\sigma L_b) \oplus \Omega(\sigma L_b) \cap L_\beta^* \oplus \sigma L_\beta^*\). Thus the problem of deciding whether \(\Omega(L_k) = \hat{Q}(L_k)\) can be broken into two parts:

(i) Under what circumstances will \(\Omega(\sigma L_b) = \hat{Q}(\sigma L_b)\)?

(ii) Is \(\Omega(L_k) = \Omega(\sigma L_b)\)?

The latter question is related to the existence of measurable cardinals [8, Chapter 12]. If \(X\) is a discrete space, then \(L_k = (L_k)_0\) is the set of all real-valued functions on \(X\) while \(\sigma L_b\) consists of those functions on \(X\) which vanish outside a countable set. It follows that for discrete spaces question (ii) is equivalent to Mackey's formulation of Ulam's problem concerning the existence of measurable cardinals [17].

We now turn our attention to question (i).

**Example.** Let \(X\) be the real line, \(\mu\) the Lebesgue measure and \(T\) the corresponding space constructed in §3. Let \(h_n \in C_k(T)\) be defined as in Example 2 at the end of §3. Then \(\{\lambda(n^{-1}h_n)\}\) is a bounded sequence for each \(\lambda \in L_k(T)\). Given a
bounded sequence \( \{r_n\} \), let \( r^\beta \) denote the extension of the function \( r \) \((r(n) = r_n)\) to \( \beta N \), the Stone-\v{C}ech compactification of the space of natural numbers. Next choose \( p \in \beta N - N \) and set \( \varepsilon_p(\{r_n\}) = r^\beta(p) \). Finally define \( \phi(\lambda) = \varepsilon_p(\{\lambda(n^{-1}h_n)\}) \) for each \( \lambda \in L_\beta(T) \). Clearly \( \phi \) is a positive linear functional on \( L_\beta(T) \). If \( \lambda \in L_\beta \), then \( |\lambda(n^{-1}h_n)| \leq n^{-1} |\lambda| (h_n) \leq n^{-1} \| \lambda \| \) and thus \( \lim_n \lambda(n^{-1}h_n) = 0 \). This implies that \( \phi \in L_\beta^* \). On the other hand \( \mu(n^{-1}h_n) = 2 + n^{-1} \); whence \( \phi(\mu) = 2 \). This shows that \( \phi \in \Omega(\sigma L_\beta) \) \((L_k = \sigma L_\beta \text{ for the space } T)\) while \( \phi \notin M_k = \overline{\Omega}(\sigma L_\beta) \).

Next we shall consider conditions which will insure that \( \Omega(\sigma L_\beta) = \overline{\Omega}(\sigma L_\beta) \). For this we will need the concept of realcompact space. Let \( \beta T \) denote the Stone-\v{C}ech compactification of a completely regular space \( T \). Then each \( f \in C(T) \) can be extended to a continuous mapping \( f^\beta \) of \( \beta T \) into the one-point compactification \( R \cup \{\infty\} \) of \( R \). Let \( vT = \{p : p \in \beta T, f^\beta(p) \neq \infty \text{ for each } f \in C(T)\} \). Clearly \( T \subset vT \subset \beta T \). When \( vT \) is given the topology induced on it by that of \( \beta T \), it is called the Hewitt realcompactification of \( T \). If \( T = vT \), then \( T \) is said to be realcompact (Hewitt used the term \( Q \)-space). A detailed study of realcompact spaces may be found in [8].

**Proposition 4.9.** Let \( f \in \Omega(L_\beta) \). If \( f \in L_\beta^* \), then \( f \) vanishes at each \( \mu \in L_k \) which has realcompact support.

**Proof.** Let \( \mu \in L_k \) and suppose that the support \( F \) of \( \mu \) is realcompact. For each \( \phi \in C(F) \), \( f^\phi \) is a multiplication operator on \( L_k(F) \) [cf. §2]. Thus the relation \( f^\phi(\mu) = f(\phi \mu) \) defines \( f^\phi \mu \) as a bounded linear functional on \( C(F) \). Since \( F \) is realcompact, \( f^\phi \mu \) has compact support \( K \) in \( F \) [11, Theorems 21 and 22]. Let \( h \in C_k \) be so that \( h(x) = 1 \) on \( K \). Then \( f(\mu) = f^\phi(1) = f^\phi(h) = f(h^\phi \mu) \). Hence if \( f \in L_\beta^* \), then \( f(\mu) = 0 \).

**Theorem 4.10.** If the support of each element of \( L_\beta \) is realcompact, then \( M_k = \Omega(\sigma L_\beta) \).

**Proof.** That \( \Omega(\sigma L_\beta) = M_k \oplus \Omega(\sigma L_\beta) \cap L_\beta^* \) was shown above. In view of Proposition 4.9, it suffices to prove that the elements of \( \sigma L_\beta \) have realcompact support. Let \( \mu \in \sigma L_\beta \). Then there exists a sequence \( \{\mu_n\} \) in \((L_\beta)_+ \) such that \( |\mu| = \bigvee_n \mu_n \). Now \( \bigvee_n(2^{-n} \| \mu_n \|^{-1}) \mu_n \) is in \( L_\beta \) and has the same support as \( \mu \). Thus the measures in \( \sigma L_\beta \) have realcompact support if those in \( L_\beta \) do.

The following is an easy consequence of Proposition 4.9.

**Theorem 4.11.** If the support of each Radon measure is realcompact, then \( M_k = \Omega(L_\beta) \).

**Remark.** Since \( \sigma \)-compact spaces are realcompact and since closed subspaces of realcompact spaces are realcompact, it follows from Theorem 4.11 that \( M_k = \Omega(L_\beta) \) for each \( \sigma \)-compact space (more generally, for each realcompact space).
5. A characterization of \( M \) and its subspaces. In [16, (7.1)], \( M, M_b \) and \( M_k \) are characterized as subrings of a ring of continuous functions. Here we shall give a slight modification of that characterization.

**Theorem 5.1.** There exist locally compact and extremally disconnected spaces \( Y \) and \( Z \) with \( Y \subset Z \) for which

(i) \( M = C(Y) = C(Z) \).

(ii) \( M_b = C_b(Y) = C_b(Z) \).

(iii) \( C_k(Y) \subset M_k \subset C_{\omega}(Y) \cap C_k(Z) \). Moreover if \( M_k \neq C_k(Y) \), then \( M_k \neq C_{\omega}(Y) \cap C_k(Z) \).

**Proof.** Let \( Y \) be the space given by [16, (7.1)]. Then \( Y \) is locally compact and extremally disconnected. Since \( M \) is the set of continuous multiplication operators on \( L_k \), (7.1) of [16] states that \( M = C(Y), M_b = C_b(Y) \) and \( C_k(Y) \subset M_k \subset C_{\omega}(Y) \).

Let \( A \) be the set of idempotents \( e \) of \( M \) such that \( eM \subset M_b \). If \( vY \) denotes the Hewitt realcompactification of \( Y \), then \( M = C(Y) = C(vY) \) [8, §8.8]. If we consider \( A \) to be a subset of \( C(vY) \), then each \( e \in A \) has compact support in \( vY \) [8, Problem 8E]. Since \( e \in C(vY) \), the support of \( e \) is open (and compact) in \( vY \). Hence the support is an open subset of \( \beta Y \). Set \( Z = \{ p : p \in vY, e(p) \neq 0 \) for some \( e \in A \} \); then \( Z \) is an open subspace of \( \beta Y \). Thus \( Z \) is locally compact. Since \( Y \) is extremally disconnected there exists for each \( y \in Y \) an element \( e \in A \) such that \( e(y) \neq 0 \). Hence \( Y \subset Z \subset vY \). This implies that \( C(Y) = C(Z), C_b(Y) = C_b(Z) \) and that \( Z \) is extremally disconnected [8, Theorem 8.6 and Problem 6M.1]. To show that \( M_k \subset C_k(Z) \) we need the following:

**Lemma 5.2.** Let \( T \) be a completely regular space. If \( f \in C = C(T) \) is such that \( fC \subset C_b \), then \( f \in C_k(vT) \).

**Proof.** For \( n = 1, 2, 3, \ldots \), every \( g \in C \) is bounded on the set \( \{ x \in vT : |f(x)| \geq 1/n \} \). Thus \( f \in C_\omega(vT) \) [8, Problem 8E]. Suppose \( f \notin C_k(vT) \). Since \( C_k(vT) = \{ h \in C : (gh)^\beta(p) = 0 \) for all \( p \in \beta T - vT \) and all \( g \in C \} \), there exists \( g \in C \) and \( p \in \beta T - vT \) such that \( (fg)^\beta(p) \neq 0 \). Hence \( f^\beta(p) \cdot (fg^2)^\beta(p) = ((fg)^\beta(p))^2 \neq 0 \). But \( f^\beta(p) = 0 \) since \( f \in C_\omega(vT) \) [8, Theorem 7.2 and Problem 7F]. This contradiction completes the proof of Lemma 5.2.

We return to the proof of Theorem 5.1. If \( f \in M_k \), then \( f \subset C_k(vT) \) [Theorem 4.5]. Thus \( f \in C_k(vY) \). Let \( e \) be the component of \( 1 \) in the closed ideal of \( M \) generated by \( f \). Then \( e \) and \( f \) have the same support in \( vY \); whence \( e \in C(vY) \) and in turn \( e \in A \subset C_k(Z) \). Therefore \( M_k \subset C_k(Z) \). It remains to show that if \( M_k \neq C_k(Y) \), then \( M_k \) is a proper subset of \( C_\omega(Y) \cap C_k(Z) \). Let \( f \in M_k, f \notin C_k(Y) \). We may suppose that \( 0 \leq f \leq 1 \) since \( f \) can be replaced by \( |f|/ \wedge 1 \). Then \( 1_f = \bigvee_n f^{1/n} \) is the component of \( 1 \) in the closed ideal generated by \( f \). Since \( f \notin C_k(Y), 1_f \notin M_k \) [16, §7]. Let \( \mu \in (L_\mu)_+ \) be such that \( 1_f \mu \notin L_b \). Now \( (f^{1/n})^\mu \uparrow 1_f^\mu \) [Proposition 4.8]. By the continuity of the norm, \( \lim_n \| (f^{1/n})^\mu \| = \infty \). Choose a subsequence \( \{ g_k \} \) of
so that \(|\text{rip}| = k^3\). Then \(g = \sum k^{-2} g_k \in C_\alpha(Y) \cap C_\alpha(Z)\) while \(g' \mu \notin L_b\). This concludes the proof of Theorem 5.1.

A topological space is pseudocompact if every continuous function defined on it is bounded.

**Corollary 5.3.** The support in \(Y\) of each element of \(M_k\) is pseudocompact.

**Proof.** Let \(F\) be the support in \(Y\) of \(f \in M_k\). Since \(Y\) is extremally disconnected, \(F\) is open. Hence the characteristic function \(e\) of \(F\) is in \(C(Y) = M\). Then \(e \in C_k(Z)\) [Theorem 5.1, (iii)]. Let \(\phi \in C(F)\) and define \(\tilde{\phi}(x) = \phi(x)\) on \(F\) and \(\tilde{\phi}(x) = 0\) on \(Y - F\). Then \(\tilde{\phi} \in C(Y) = C(Z)\). Thus \(e \tilde{\phi} \in C_k(Z)\). Therefore \(\phi\) is bounded.

**Remark.** Corollary 5.3 is stated in [16]. However the proof given there rests on a lemma [16, lemma following (7.8)] which is invalid for non-normal spaces. The Tychonoff plank affords a counterexample.

**Example.** Let \(X\) be the real line, \(\mu\) the Lebesgue measure and \(T\) the corresponding space constructed in the proof of Theorem 3.1. Also, let \(h_n \in C_\alpha(T)\) be defined as in Example 2 at the end of §3. Then \(f = \sum n^{-3} h_n\) and \(g = \sum n^{-2} h_n\) are elements of \(C_\alpha(T)\). From the information derived in Example 2 at the end of §3, it follows that \(f \in M_k\) while \(\sum n^{-2} \mu(h_n) = \sum (2n + 1)n^{-2}\). Therefore \(g \notin M_k\). Clearly \(f\) and \(g\) have the same support in \(Y\). This example shows that in general \(M_k\) is not equal to \(C_k(Y)\) and thus it answers the question raised by Kaplan in [16, §§5, 7].

**Proposition 5.4.** If each measure in \(L_b\) has realcompact support, then \(M_k = C_k(Y)\).

**Proof.** Let \(f \in M_k\) and \(\mu \in \sigma L_b\). Then \(f' \mu\) has compact support (see the proof of Proposition 4.9). If \(1_f\) is the characteristic function of the support of \(f\), then \(1_f' \mu\) also has compact support; whence \(1_f' \mu \in L_b\). It follows from Theorem 4.5 that \(1_f \in M_k\). Thus \(M_k = C_k(Y)\) [16, (5.2) and (7.2)].

**Remark.** Proposition 5.4 is equally valid whether the support of \(\mu \in L_b\) is taken in \(X\) or whether \(\mu\) is considered as a measure on \(Y\) and the support of \(\mu\) is taken in \(Y\).

The following is due to Kaplan [15, (3.4)] and [16, proof of 7.1, (i)].

**Proposition 5.5.** (i) \(L = \hat{\Omega}(M_k) = \hat{\Omega}(C_k(Y))\).
(ii) \(L_b = \hat{\Omega}(M_b)\).

**Proposition 5.6.** The set \(X\) can be identified with the set of isolated points of \(Y\).

**Proof.** For \(x \in X\), \(R\varepsilon_x\) is a closed ideal in \(L_b(X) = \hat{\Omega}(C_k(Y))\). Thus \(R\varepsilon_x\) is a one-dimensional ideal in \(L_b(Y) = \Omega(C_k(Y))\) and hence the support in \(Y\) of \(\varepsilon_x\) consists of a single point \(y\). Therefore \(\varepsilon_x = \varepsilon_y\) [Proposition 2.2]. Since \(\varepsilon_y \in \hat{\Omega}(C_k(Y))\), \(y\) is an isolated point [Proposition 2.3]. Conversely, suppose \(y\) is an isolated
point of $Y$. Then $\varepsilon_x \in \tilde{\Omega}(C_\alpha(Y)) = L_\alpha(X)$ and $Re_\varepsilon$ is a one-dimensional ideal. Hence the support in $X$ of $\varepsilon_x$ consists of a single point $x$. Thus $\varepsilon_x = \varepsilon_x$ [Proposition 2.2].

We shall consider $X$ both as a topological space with its original topology and as a subset of $Y$. When we refer to the topology on $X$, we shall mean the original topology rather than the topology induced on $X$ by that of $Y$. These topologies differ widely unless the original topology is discrete.

Since $L_k = (L_k)_0 \oplus (L_k)_1$, it follows that $(\bigcup L(K))_0$ and $(\bigcup L(K))_1$ are direct summands of $\bigcup L(K)$. Define $M_0 = \Omega((\bigcup L(K))_0)$ and $M_1 = M'_0$. Then $M = M_0 \oplus M_1$ and $M_1$ is the order dual of $(\bigcup L(K))_1$ [16, §2]. For $f \in M$, let $f_0$ and $f_1$ denote the components of $f$ in $M_0$ and $M_1$ respectively. If $A$ is a subset of $M$, denote $\{f_0 : f \in A\}$ by $A_0$ and $\{f_1 : f \in A\}$ by $A_1$. Then it follows that $(M_0)_0 = M_0 \cap M_1$, $(M_1)_1 = M_1 \cap M_k$ and $M_k = (M_k)_0 \oplus (M_k)_1$. Similar statements hold for $M_b$.

A real-valued function on a topological space is said to be locally bounded if it is bounded on some neighborhood of each point of the space.

**Proposition 5.7.** (i) $M_0$ is lattice and ring isomorphic with the lattice-ordered ring of all locally bounded functions on $X$. (The lattice and ring operations are defined pointwise.)

(ii) $(M_k)_0$ is isometric and lattice and ring isomorphic with the Banach lattice-ordered ring of all bounded real-valued functions on $X$. (The norm is given by: $\|f\| = \sup \{|f(x)| : x \in X\}$.)

**Proof.** We shall show that the isomorphism is given by $f \mapsto f|X$. Suppose $f \in M_0$ is not locally bounded on $X$. Then there exists $p \in X$ such that $f$ is unbounded on each neighborhood of $p$. Let $K$ be a compact neighborhood of $p$ and select a sequence $\{x_n\}$ from $K$ so that $|f(x_n)| \geq n^2$. Let $\mu \in (L_k)_0$ be such that $\mu(x_n) = n^{-2}$ and $\mu(x) = 0$ for $x \neq x_n, n = 1, 2, 3, \ldots$. Then $\mu \in L(K)$. On the other hand $|f(\mu)| \geq n^{-2} |f(x_n)| \geq n$. This proves that each $f \in M_0$ is locally bounded on $X$. If $\phi$ is a locally bounded function on $X$, then $\phi$ is bounded on each compact subset of $X$. Hence $f(\mu) = \sum_{x \in X} \phi(x) \mu(x)$, $\mu \in (\bigcup L(K))_0$ defines $f$ as an element of $M_0$ such that $|f|X = \phi$. Since $M = \Omega((\bigcup L(K))$ and since $(L_k)_0$ is the closure of the linear space generated by $\{\varepsilon_x : x \in X\}$, it follows that $f \in M_0$ is $> 0$ if and only if $f|X > 0$. Thus $f \mapsto f|X$ is a lattice isomorphism. Clearly it is also a ring isomorphism. Part (ii) follows from (i) and the order unit property of 1.

Let $Y_0$ be the closure with respect to the topology on $Y$ of the set $X$. Then define $Y_1 = Y - Y_0$. Since $X$ is a discrete and hence open subset of the extremally disconnected space $Y$, the sets $Y_0$ and $Y_1$ are open. Thus we have:

**Proposition 5.8.** (i) $M_0 = C(Y_0)$, $M_1 = C(Y_1)$,

(ii) $(M_k)_0 = C_k(Y_0)$, $(M_k)_1 = C_k(Y_1)$,

(iii) $C_k(Y_0) \subset (M_k)_0 \subset C_\alpha(Y_0)$, $C_k(Y_1) \subset (M_k)_1 \subset C_\alpha(Y_1)$. 

License or copyright restrictions may apply to redistribution; see https://www.ams.org/journal-terms-of-use
In general it is not possible to characterize \((M_k)_0\) by means of topological terms alone. However, we can obtain the following:

**Proposition 5.9.** (i) Let \(f \in M_0\). If \(f\) has compact support in \(X\), then \(f \in M_k\). (ii) The support in \(X\) of each \(f \in (M_k)_0\) is pseudocompact.

**Proof.** Part (i) follows from the characterization of \((Lk)_0\) given in Proposition 2.6. To prove (ii), let \(f \in M_0\) and suppose that the support \(F\) in \(X\) of \(f\) is not pseudocompact. Then there exists an unbounded \(\phi \in C(F)\). Define \(\tilde{\phi}(x) = \phi(x)\) on \(F\) and \(\tilde{\phi}(x) = 0\) on \(X - F\); then \(\tilde{\phi}\) is locally bounded on \(X\) and hence \(\tilde{\phi} \in M_0\). Also, \(\tilde{\phi}\) is unbounded on the set \(\{x : x \in X, f(x) \neq 0\}\). Therefore \(\tilde{\phi}\) is unbounded on the support in \(Y\) of \(f\). Hence \(f \notin M_k\) [Corollary 5.3].

**Remark.** Since compactness and pseudocompactness are equivalent for \(\sigma\)-compact spaces (more generally, for realcompact spaces), Proposition 5.9 gives a complete characterization of \((M_k)_0\) for such spaces.

**Example.** Let \(X\) be the real line, \(\mu\) be the Lebesgue measure and \(T\) be the corresponding space constructed in the proof of Theorem 3.1. Let \(f\) be the element of \(M_k\) defined in the example following Corollary 5.3. Then the support of \(f_0\) in \(T\) (\(T\) plays the role of \(X\) in Proposition 5.9) is \(T\) itself. However, \(T\) is not compact since it admits a measure, namely \(\mu\), which is not finite.

We now investigate the connection between \(M\) and the subspaces \(C, C_b\) and \(C_k\).

**Proposition 5.10.** (i) Let \(f \in M\), \(g \in M\). Then \(f \leq g\) if and only if \(fh \leq gh\) for all \(h \in (C_k)_+\). (ii) Let \(\{f_\alpha\}\) be a net in \(M\). Then \(\{f_\alpha\}\) converges if and only if \(\{f_\alpha h\}\) converges for each \(h \in (C_k)_+\).

**Proof.** Statement (i) and the necessity part of (ii) follow easily from Theorem 5.1 and Proposition 2.12. We shall prove the sufficiency part of (ii). If \(\mu \in L_k\), \(h \in (C_k)_+\), then \(\lim \| f_\alpha h \|_\mu = \lim \| f_\alpha h \|_\mu [15, (3.7)] = \lim \| f_\alpha \|_\mu\). Since \(C_k L_k = \bigcup L(K)\) [Proposition 2.12], it follows that \(\lim \| f_\alpha \|_\mu\) exists for each \(\mu \in \bigcup L(K)\). Clearly, the relation \(f(\mu) = \lim \| f_\alpha \|_\mu\) defines \(f\) as a linear functional on \(\bigcup L(K)\). Now \(\{f_\alpha h\}\) converges if \(\{f_\alpha \}\) converges; thus \(\lim \| f_\alpha \|_\mu\) exists for each \(\mu \in \bigcup L(K)\). If \(\mu \leq \lambda\), then \(\| f(\mu) \| = \lim \| f_\alpha \|_\mu \leq \lim \| f_\alpha \|_\lambda\). Therefore \(f\) is bounded and \(f \in M\). Now \(f(\mu) = f(h'\mu) = \lim \| f_\alpha h(\mu) \| = \lim \| f_\alpha \|_\mu\); whence \(f = \lim f_\alpha\) for each \(h \in (C_k)_+\). It remains to show that \(f = \lim f_\alpha\). Let \(A_\beta\) be the set of suprema of finite subsets of \(\{ \| f - f_\beta \| : \beta \geq \alpha \}\). Then \(\{ g(\mu) : g \in A_\beta \}\) is bounded for each \(\mu \in \bigcup L(K)\); therefore \(\bigvee A_\beta = \bigvee \bigvee \| f - f_\beta \| \) exists in \(M\) [6, Théorème 1]. Set \(g_\alpha = \bigvee \| f - f_\beta \|\). For any compact set \(K \subset X\) and any \(g \in M\), \(g_\alpha\) denotes the component of \(g\) in \(M(K)\). Choose \(\phi \in (C_k)_+\) so that \(\phi(x) = 1\) on \(K\); then \(\bigvee g_\alpha = \bigvee \| f - f_\beta \|_K [14, (1.4)] \leq \bigvee |f| \bigvee \| f \| = 0\). Since \(\bigvee M(K)\) is dense in \(M\), \(\bigvee g_\alpha = 0\). This proves that \(\lim f_\alpha = f\).
An element \( f \in C \) is completely determined by its values on \( X \). Hence we have

**Proposition 5.11.** \( C_0 \) is ring and lattice isomorphic with \( C \). Furthermore, \( (C_0)_0 \) is isometric with \( C_b \).

**Proposition 5.12.** Let \( f \in C \) and \( A \subset C \); then \( f = \bigvee A \) if and only if \( f_0 = \bigvee A_0 \).

**Proof.** Since adding to \( A \) the suprema of finite subsets of \( A \) will alter neither \( \bigvee A_0 \) nor \( \bigvee A \), we may suppose that \( A \) is directed upward. Then \( f = \bigvee A \) if and only if \( fh = \bigvee hA \) [Proposition 5.10] for every \( h \in (C_0)_+ \). Since \( hA \subset M(K) \) for some compact set \( K \), the proposition now follows from [14, (5.5)].

6. The duality between \( L_k \) and \( M \). For a subset \( A \) of \( L_k \), let \( A^* \) denote the annihilator of \( A \) in \( M \), i.e., \( A^* = \{ f : f \in M, f^\prime \mu = 0 \text{ for all } \mu \in A \} \). Similarly for \( B \subset M \), define \( B^* = \{ \mu : \mu \in L_k, f^\prime \mu = 0 \text{ for all } f \in B \} \). We need the following:

**Lemma 6.1.** Let \( f \in M, \mu \in L_k \). Then \( |f| \mu = |f| |\mu|, (f^\prime \mu)^+ = (f^+) \mu^+ + (f^-) \mu^- \) and \( (f^\prime \mu)^- = (f^+) \mu^- + (f^-) \mu^+ \).

**Proof.** First suppose that \( \mu \geq 0 \). Then \( (f^+) \mu^+ \) and \( (f^-) \mu^- \) are disjoint [Theorem 5.1 and 16, (8.2)]. Whence \( (f^\prime \mu)^+ = (f^+) \mu^+ \). Now let \( \mu \) be an arbitrary element of \( L_k \). Since \( f^\prime \mu \) is a multiplication operator \( f^\prime \mu^+ \) and \( f^\prime \mu^- \) are disjoint. Therefore \( (f^\prime \mu)^+ = (f^+ \mu^+ + (-f) \mu^-)^+ = (f^+ \mu^+) + ((-f) \mu^-)^+ \). The assertion concerning \( (f^\prime \mu)^+ \) now follows from the first part of this proof. The remainder of the lemma follows from standard vector lattice properties.

**Proposition 6.2** (i) For any subset \( A \) of \( L_k \), \( A^* \) is a closed ideal in \( M \).

(ii) For any subset \( B \) of \( M \), \( B^* \) is a closed ideal in \( L_k \).

**Proof.** (i) Let \( g \in M, f \in A^* \) be such that \( |g| \leq |f| \). Then \( |g^\prime \mu| = |g| |\mu| \leq |f| |\mu| = |f^\prime \mu| = 0 \text{ for all } \mu \in A \). Thus \( g \in A^* \). This shows that \( A^* \) is an ideal. Since the mapping \( f \mapsto f^\prime \mu \) is continuous \( A^* \) is closed. The proof of (ii) is similar to that of (i).

**Remark.** If \( A \subset \bigcup L(K) \), then \( A^* \) is the null ideal [15, §2] of \( A \) in \( M \). Likewise if \( B \subset M_k \), then \( B^* \) is the null ideal in \( L_k \) of \( B \). More generally, if \( A \subset L_k \) and \( I \) is the ideal in \( L_k \) generated by \( A \), then \( A^* = (I \cap \bigcup L(K))^\perp \). A similar statement holds for subsets of \( M \).

For \( \mu \in L_k \), let \( (L_k)_\mu \) denote the closed ideal in \( L_k \) generated by \( \mu \). For \( A \subset L_k \), let \( A_\mu \) denote the set of components in \( (L_k)_\mu \) of the elements of \( A \). In particular \( (L_0)_\mu = L_0 \cap (L_k)_\mu \). Next define \( M_\mu = \{ \mu \}^{\times \infty} \). Then \( M'_\mu = \{ \mu \}^{\times \infty} \) and \( M = M_\mu \oplus M'_\mu \). It follows that \( M_\mu = \Omega((L_0)_\mu \cap \bigcup L(K)) \) and that \( M_\mu \) can be identified with the set of all multiplication operators on \( (L_k)_\mu \). For \( f \in M \), let \( f_\mu \) denote the component of \( f \) in \( M_\mu \). Given a subset \( B \) of \( M \), set \( B_\mu = \{ f_\mu : f \in B \} \). Observe that \( (M_\mu)_\mu = M_\mu \cap M_\mu \) and \( (M_\mu)_\mu = M_\mu \cap M_\mu \). Also \( I_\mu \) is the ring identity and strong order unit for \( M_\mu \). It is also easy to verify that \( I_\mu M = M_\mu \).
**Proposition 6.3.** Let $\mu \in (L_k)_+$, $f \in M_\mu$, $g \in M_\mu$. Then $g \leq f$ if and only if $g'\mu \leq f'\mu$.

**Proof.** The “only if” part follows from the definition of the order in $M$. Suppose $g'\mu \leq f'\mu$. Then $(f - g)^-\mu = (f - g)'\mu^- \geq 0$. Thus $(f - g)^- \in M'_\mu \cap M_\mu$; whence $(f - g)^- = 0$. This proves that $g \leq f$.

**Theorem 6.4.** For each $\mu \in L_k$, $\mu M = \{f'\mu; f \in M\}$ is a dense ideal in $(L_k)_\mu$.

**Proof.** Since $f'$ is a multiplication operator on $M$, $f'\mu \in (L_k)_\mu$; whence $\mu M \subseteq (L_k)_\mu$. It follows from [16, (9.1)] that $(L_k)_\mu$ is the closure of $\mu M$. It remains to show that $\mu M$ is an ideal. Lemma 6.1 insures that $\mu M$ is a subvector lattice of $L_k$. The theorem will now follow from

**Lemma 6.5.** Let $\mu \in (L_k)_+$, $f \in M_\mu$ and $\lambda \in L_k$ be such that $0 \leq \lambda \leq f'\mu$. Then there exists a $g \in M_\mu$ such that $g'\mu = \lambda$.

**Proof.** Set $g = \sqrt{f} \in M_\mu$. Observe that the $h$'s are bounded by $f$ [Proposition 6.3]. Thus $g \in M_\mu$. It remains to show that $g'\mu = \lambda$. In any case $v = \lambda - g'\mu \geq 0$ [Proposition 4.8]. Assume $v > 0$. Now $(v - n^{-1}\mu)^+ \uparrow v$. Thus there is a positive number $r$ such that $(v - r\mu)^+ > 0$. Let $e = 1_{(v - r\mu)^+}$. Then $e'\mu \geq e' (v - r\mu) > 0$. Thus $(g + re)^\mu = \lambda - v + re'\mu < \lambda$. Since $g + re \in M_\mu$, it follows from the manner in which $g$ was defined that $g + re \leq g$. This is a contradiction since $r > 0$ and $e > 0$. Thus $\lambda = g'\mu$.

**Theorem 6.6.** Let $\mu \in L_k$. Then each $\lambda \in (L_k)_\mu$ is the limit of a sequence in $\mu M_\mu = \{f'\mu; f \in M_\mu\}$.

**Proof.** Since $(L_k)_\mu = (L_k)|_{\mu}$ and since $\lambda^+$ and $\lambda^-$ can be considered separately we may assume that $\mu \geq 0$ and $\lambda \geq 0$. Since $\mu M$ is a dense ideal in $(L_k)_\mu$, there exists a net $\{f_n\}$ in $M$ such that $f_n'\mu \uparrow \lambda$. Set $g_n = \sqrt{\lambda} f_n \wedge 1$, $n = 1, 2, 3, \ldots$. It follows easily that $g_n'\mu \uparrow \lambda$.

**Remark.** Theorems 6.4 and 6.6 are weakened forms of the Radon-Nikodym theorem.

Since $L_k(X) = \bar{\Omega}(C_k(Y)) \subseteq \Omega(C_k(Y)) = L_k(Y)$, each $\mu \in L_k(X)$ can be considered both as a measure on $X$ and as a measure on $Y$. Of particular interest is the support of $\mu$ in $Y$. Whenever we write $L_k$, we shall mean $L_k(X)$ rather than $L_k(Y)$.

**Proposition 6.7.** Let $\mu \in L_k$. Then the supports in $Y$ of $\mu$ and $1_\mu$ are identical.

**Proof.** Since $1_\mu'\mu = \mu$, the support of $1_\mu$ contains that of $\mu$ [3, Proposition 10, p. 73]. For $p \in Y$ not belonging to the support of $\mu$, let $f \in M = C(Y)$ vanish on the support of $\mu$ while $f(p) \neq 0$. Then $f'\mu = 0$ [3, p. 72]. Hence $(f1_\mu)'\mu = 0$; thus $f1_\mu \in M'_\mu \cap M_\mu$. This implies that $f1_\mu = 0$; whence it follows that $1_\mu$ vanishes on a neighborhood of $p$.
Corollary 6.8. The support in \( Y \) of each element of \( L_k \) is open (and closed).

Proposition 6.9. \( \tilde{\Omega}(M) = \{ \mu \in L_b, \mu \text{ has pseudocompact support in } Y \} \).

Proof. By [16, (2.7)], \( \tilde{\Omega}(M) \subset \tilde{\Omega}(M_b) = L_b \). Let \( \mu \in L_b \) have pseudocompact support in \( Y \). Then \( \mu M \subset M_b \); thus the relation \( \mu(f) = \mu(f1_\mu) \) extends \( \mu \) to become an element of \( \Omega(M) \). Clearly, then \( \mu \in \tilde{\Omega}(M) \). To prove the converse inclusion it suffices to show that if \( \mu \in \tilde{\Omega}(M) \), then \( f1_\mu \in M_b \) for all \( f \in M \) [cf. Lemma 5.2 and Corollary 5.3]. Let \( \mu \in \tilde{\Omega}(M) \). It follows from [11, Theorems 13 and 14] that there exists \( g \in M_b \) such that \( |\mu|(|f - g|) = 0 \). Then \( f - g \) vanishes on the support of \( \mu \) [3, §3, Proposition 9, Chapitre III] and hence \( f1_\mu = g1_\mu \in M_b \).

Proposition 6.10. (i) \( \bigcup L(K) \subset C_k(Y)L_k \subset M_kL_k \subset C_k(Z)L_b = \tilde{\Omega}(M) \).
(ii) If \( I \) is any one of the ideals listed in (i), then \( M = \Omega(I) = \tilde{\Omega}(I) \).

Proof. Clearly the first two inclusions in (i) are valid. Now \( M_kL_k \subset L_b \) and \( M_kC_k(Z) = M_k \); whence \( M_kL_k \subset C_k(Z)L_b \). That \( \tilde{\Omega}(M) = C_k(Z)L_b \) follows from Proposition 6.9 and the manner in which the space \( Z \) was constructed [cf. Theorem 5.1]. We now consider the proof of (ii). Since \( \bigcup L(K) \) is a dense ideal in \( L_k \) and \( M = \tilde{\Omega}(\tilde{\Omega}(M)) \), it follows from [16, (2.7)] that \( M = \tilde{\Omega}(I) \) for each of the ideals mentioned in part (i). The proof that \( \Omega(I) = \tilde{\Omega}(I) \) can be patterned after the proof of Proposition 4.1 (i).
