ON THE MAXIMALITY OF
SUMS OF NONLINEAR MONOTONE OPERATORS

BY
R. T. ROCKAFELLAR

1. Introduction. Let $X$ be a real Banach space and let $X^*$ be the dual of $X$, with $\langle x, x^* \rangle$ written in place of $x^*(x)$. A monotone operator from $X$ to $X^*$ is a (generally multivalued) mapping $T$ such that

\begin{equation}
\langle x - y, x^* - y^* \rangle \geq 0 \quad \text{whenever } x^* \in T(x), \ y^* \in T(y).
\end{equation}

Such an operator $T$ is said to be maximal if its graph, i.e. the set

\begin{equation}
G(T) = \{ (x, x^*) \mid x \in X, x^* \in T(x) \} \subseteq X \times X^*
\end{equation}

is not properly contained in the graph of any other monotone operator $T' : X \rightarrow X^*$. The set

\begin{equation}
D(T) = \{ x \in X \mid T(x) \neq \emptyset \}
\end{equation}

is called the effective domain of $T$, and $T$ is said to be locally bounded at a point $x \in D(T)$ if there exists a neighborhood $U$ of $x$ such that the set

\begin{equation}
T(U) = \bigcup \{ T(u) \mid u \in U \}
\end{equation}

is a bounded subset of $X$.

It is apparent that, given any two monotone operators $T_1$ and $T_2$ from $X$ to $X^*$, the operator $T_1 + T_2$ is again monotone, where

\begin{equation}
(T_1 + T_2)(x) = T_1(x) + T_2(x) = \{ x_1^* + x_2^* \mid x_1^* \in T_1(x), x_2^* \in T_2(x) \}.
\end{equation}

If $T_1$ and $T_2$ are maximal, it does not necessarily follow, however, that $T_1 + T_2$ is maximal—some sort of condition is needed, since for example the graph of $T_1 + T_2$ can even be empty (as happens when $D(T_1) \cap D(T_2) = \emptyset$).

The problem of determining conditions under which $T_1 + T_2$ is maximal turns out to be of fundamental importance in the theory of monotone operators. Results in this direction have been proved by Lescarret [9] and Browder [5], [6], [7]. The strongest result which is known at present is:

**Theorem (Browder [6], [7]).** Let $X$ be reflexive, and let $T_1$ and $T_2$ be monotone operators from $X$ to $X^*$. Suppose that $T_1$ is maximal, $D(T_2) = X$, $T_2$ is single-valued.
and hemicontinuous (i.e. continuous from line segments in $X$ to the weak* topology in $X^*$), and $T_2$ carries bounded sets into bounded sets. Then $T_1 + T_2$ is a maximal monotone operator.

The conditions here on $T_2$ imply in particular that $T_2$, like $T_1$, is maximal (Browder [3, Theorem 1.2]).

The purpose of this paper is to establish the following considerably more general result (where int and cl denote interior and (strong) closure, respectively).

**THEOREM 1.** Let $X$ be reflexive, and let $T_1$ and $T_2$ be maximal monotone operators from $X$ to $X^*$. Suppose that either one of the following conditions is satisfied:

(a) $D(T_1) \cap \text{int} D(T_2) \neq \emptyset$, or

(b) there exists an $x \in \text{cl} D(T_1) \cap \text{cl} D(T_2)$ such that $T_2$ is locally bounded at $x$. Then $T_1 + T_2$ is a maximal monotone operator.

Conditions (a) and (b) of Theorem 1 are actually equivalent, as we have shown elsewhere [16, Theorem 1].

The derivation of Theorem 1 will rest heavily on the theory already developed by Browder in [6] and elsewhere. In the case where $T_1$ and $T_2$ are the subdifferentials of lower semicontinuous proper convex functions on $X$ [12], [13], Theorem 1 could be deduced, however, directly from Fenchel's duality theorem and related results [11].

When $X$ is finite-dimensional, Theorem 1 may be refined slightly in terms of relative interiors. (The relative interior of a subset $C$ of $X$, denoted by $\text{ri} C$, is the interior of $C$ relative to the affine hull of $C$, which is the intersection of all the hyperplanes containing $C$.)

**THEOREM 2.** Let $X$ be finite-dimensional, and let $T_1$ and $T_2$ be maximal operators from $X$ to $X^*$ such that

$$\text{ri} D(T_1) \cap \text{ri} D(T_2) \neq \emptyset.$$ 

One of the main motivations behind Theorems 1 and 2 is that such results make it possible, as Browder has remarked [6, p. 92], to derive theorems about "variational inequalities" from fundamental theorems about the ranges and effective domains of (multivalued) maximal monotone operators. Some applications of this sort will be considered in §4. For the sake of applications to a class of variational inequalities studied in terms of hemicontinuity by Hartman-Stampacchia [8] and Browder [4], it will be useful to have, along with Theorems 1 and 2, the following special maximality theorem.

We shall say that an element $x^* \in X^*$ is normal to a convex subset $K$ of $X$ at a point $x$ if

$$x \in K \quad \text{and} \quad \langle u-x, x^* \rangle \leq 0, \quad \forall u \in K.$$ 

For each $x \in X$, the set of all $x^*$ normal to $K$ at $x$ is classically called the normal
cone to $K$ at $x$. The normal cone to $K$ at $x$ is a weak* closed convex cone in $X^*$, empty by definition when $x \notin K$, but containing at least the zero vector of $X^*$ (and hence nonempty) when $x \in K$. The multivalued mapping from $X$ to $X^*$ which assigns to each $x \in X$ the normal cone to $K$ at $x$ will be referred to as the normality operator for $K$. (This mapping is actually the subdifferential of the indicator of $K$, so that it is a maximal monotone operator with effective domain $K$, if $K$ is a nonempty closed convex set [12], [13].)

Theorem 3. Let $K$ be a nonempty closed convex subset of $X$ (where $X$ is not necessarily reflexive), and let $T_1 : X \to X^*$ be the normality operator for $K$. Let $T_2 : X \to X^*$ be any single-valued monotone operator (not necessarily maximal) such that $D(T_2) \supseteq K$ and $T_2$ is hemicontinuous on $K$, i.e. continuous along each line segment in $K$ with respect to the weak* topology of $X^*$. Then $T_1 + T_2$ is a maximal monotone operator.

2. Preliminary results. In this section we shall only be concerned with the case where $X$ is reflexive. Asplund [1] has shown by means of a theorem of Lindenstrauss that, in this case, there exists an equivalent norm on $X$ which is everywhere Gâteaux differentiable except at the origin and whose polar norm on $X^*$ is everywhere Gâteaux differentiable except at the origin. (Under such a norm, the unit balls of $X$ and $X^*$ are strictly convex.) For notational simplicity, we may assume that the given norm on $X$ already has these special properties. We denote by $J$ the Gâteaux gradient of the function $h(x) = (1/2)\|x\|^2$. Thus $J$ is the duality mapping which assigns to each $x \in X$ the unique $J(x) \in X^*$ such that

$$\langle x, J(x) \rangle = \|x\|^2 = \|J(x)\|^2.$$  

(See [2].) As is known, $J$ maps $X$ one-to-one onto $X^*$ and is continuous from the strong topology to the weak* topology. Also, $J$ is a strictly monotone operator, i.e.

$$\langle x - y, J(x) - J(y) \rangle > 0 \quad \text{when } x \neq y.$$ 

For any monotone operator $T$ from $X$ to $X^*$, we define the mapping $T^{-1}$ by

$$T^{-1}(x^*) = \{x \mid x^* \in T(x)\}.$$ 

It is obvious that $T^{-1}$ is a monotone operator from $X^*$ to $X$, and (assuming $X$ to be reflexive) $T^{-1}$ is maximal if and only if $T$ is maximal. We denote the range of $T$ by $R(T)$. Thus

$$R(T) = D(T^{-1}) = \bigcup \{T(x) \mid x \in X\}.$$ 

The main tool which we shall use in proving Theorem 1 is a generalization, essentially due to Browder [6], of the fundamental Hilbert space theorem of Minty [10].

Proposition 1. Let $X$ be reflexive, and let $J$ be the duality mapping defined above. Let $T : X \to X^*$ be any maximal monotone operator. Then, for any $\lambda > 0$, $R(T + \lambda J)$
is all of $X^*$ and $(T+\lambda J)^{-1}$ is a single-valued maximal monotone operator from $X^*$ to $X$ which is demicontinuous, i.e. continuous from the strong topology to the weak topology.

**Proof.** If $0 \in D(T)$, this follows from the argument given by Browder at the beginning of the proof of Theorem 4 of [6], except that Lemma 10 of [6] should be invoked in place of Lemma 8. We want to use this result, however, even in the case where $0 \notin D(T)$, so we must give a somewhat modified proof. Let $a \in D(T)$, and let $T_1$ and $T_2$ be the monotone operators defined by

$$T_1(x) = T(x+a), \quad T_2(x) = \lambda J(x+a).$$

Then $0 \in D(T_1)$, and $T_1$ and $T_2$ satisfy the hypothesis of Theorem 1 of [6], as is easily verified. This implies that $R(T_1+T_2)$ is all of $X^*$, and of course $R(T_1+T_2)$ is the same as $R(T+\lambda J)$. Also, $T+\lambda J$ is a maximal monotone operator by Theorem 2 of [6](2). Thus $(T+\lambda J)^{-1}$ is a maximal monotone operator from $X^*$ to $X$ whose effective domain is all of $X^*$. We shall show that $(T+\lambda J)^{-1}$ is single-valued, and this will imply by Rockafellar [14, Corollary 1 to Theorem 1] that $(T+\lambda J)^{-1}$ is demicontinuous. Let $x$ and $y$ be elements of $(T+\lambda J)^{-1}(x^*)$, and let

$$x^* = u^* - \lambda J(x) \in T(x), \quad y^* = u^* - \lambda J(y) \in T(y).$$

Since $T$ is monotone, we have

$$0 = \langle x-y, u^*-u^* \rangle = \langle x-y, (x^*+\lambda J(x))-(y^*+\lambda J(y)) \rangle$$
$$= \langle x-y, x^*-y^* \rangle + \lambda \langle x-y, J(x)-J(y) \rangle$$
$$\geq \lambda \langle x-y, J(x)-J(y) \rangle,$$

and this implies $x=y$ by (2.2).

**Corollary.** Let $X$ be reflexive, and let $J$ be the duality mapping defined above. Let $T: X \to X^*$ be a monotone operator. In order that $T$ be maximal, it is necessary and sufficient that $R(T + J)$ be all of $X^*$.

**Proof.** By Zorn's Lemma, there exists a maximal monotone operator $T': X \to X^*$ such that $T'(x) \supseteq T(x)$ for every $x$. Applying Proposition 1 to $T'$ with $\lambda=1$, one sees that, for each $u^* \in X^*$, there exist unique elements $x \in X$ and $x^* \in X^*$ such that $x^* \in T'(x)$ and $x^* + J(x) = u^*$. Therefore, $T=T'$ if and only if each $u^* \in X^*$ can actually be expressed in the form $x^* + J(x)$ for some $x \in X$ and $x^* \in T(x)$, i.e. if and only if $R(T+J)=X^*$.

The next result may be regarded as a generalization of Theorem 2.2 of Browder [3]. Its proof is derived from Browder’s proof of Theorem 3 of [6].

**Proposition 2.** Let $X$ be reflexive, and let $T: X \to X^*$ be a maximal monotone operator. Suppose there exists an $\alpha > 0$ such that

$$\langle x, x^* \rangle \geq 0 \quad \text{whenever} \quad \|x\| > \alpha, \ x \in D(T), \ x^* \in T(x).$$

(2) The hypothesis in Theorem 1 of [6] that $T_1$ have a dense domain is superfluous—it is nowhere used in the proof nor mentioned in the rest of the paper.
Then there exists an \( x \in X \) such that
\[
0 \in T(x).
\]

**Proof.** We can assume that the given norm on \( X \) has the special properties described above. Let \( U_\alpha \) be the closed ball of radius \( \alpha \) around the origin of \( X \). The set
\[
T(U_\alpha) = \bigcup \{ T(x) \mid \|x\| \leq \alpha \}
\]
is closed in \( X^* \); see Rockafellar [14, Lemma 2]. Hence, to show that \( 0 \in T(U_\alpha) \), it suffices to show that \( T(U_\alpha) \) meets every ball of positive radius about the origin of \( X^* \). Let \( J \) be the duality mapping defined above. Given any \( \varepsilon > 0 \), there exists by Proposition 1 an \( x \in X \) such that
\[
0 \in (T+(\varepsilon/\alpha)J)(x).
\]
Setting \( x^* = -(\varepsilon/\alpha)J(x) \), we have \( x^* \in T(x) \) and
\[
0 = \langle x, x^* \rangle + (\varepsilon/\alpha)\langle x, J(x) \rangle,
\]
or equivalently by (2.1)
\[
\langle x, x^* \rangle = -(\varepsilon/\alpha)\|x\|^2.
\]
If we had \( \|x\| > \alpha \), the left side of (2.8) would be nonnegative by (2.5), whereas the right side would be negative, a contradiction. Therefore \( \|x\| = \alpha \) and
\[
\|x^*\| = (\varepsilon/\alpha)\|J(x)\| = (\varepsilon/\alpha)\|x\| \leq \varepsilon.
\]
This shows that \( T(U_\alpha) \) meets the closed ball of radius \( \varepsilon \) about the origin of \( X^* \), and the proof is complete.

Besides the important device of perturbing a monotone operator \( T \) to an operator of the form \( T + \lambda J \), we shall need to use a device of "truncation" in proving Theorem 1. For each \( \alpha > 0 \), we shall denote by \( B_\alpha \) the subdifferential of the indicator function of the closed ball \( U_\alpha \) of radius \( \alpha \) about the origin in \( X \) (with respect to a norm on \( X \) having the special properties described above). Thus \( B_\alpha \) is the normality operator for \( U_\alpha \), so that \( B_\alpha(x) = \emptyset \) when \( \|x\| > \alpha \), \( B_\alpha(x) \) consists of solely the zero element of \( X^* \) when \( \|x\| < \alpha \), and
\[
B_\alpha(x) = \{ \lambda J(x) \mid \lambda \geq 0 \} \quad \text{when} \quad \|x\| = \alpha.
\]
It is known that \( B_\alpha \) is a maximal monotone operator (Rockafellar [12], [13]). In particular, therefore, if \( T: X \to X^* \) is any monotone operator, \( T + B_\alpha \) is a monotone operator. Note that
\[
(T+B_\alpha)(x) = T(x) \quad \text{when} \quad x \in \text{int} \ U_\alpha,
\]
\[
D(T+B_\alpha) = D(T) \cap U_\alpha.
\]

**Proposition 3.** Let \( X \) be reflexive, and let \( T: X \to X^* \) be a monotone operator
such that $0 \in D(T)$. Suppose there exists an $\alpha_0 > 0$ such that the monotone operator $T + B_\alpha$ is maximal for every $\alpha \geq \alpha_0$, where $B_\alpha$ is the mapping defined above. Then $T$ is maximal.

**Proof.** Subtracting a constant mapping from $T$ if necessary, we can reduce to the case where $0 \in T(0)$. Let $J$ be the duality mapping defined above, and let $u^*$ be an arbitrary element of $X^*$. To prove that $T$ is maximal, it suffices, according to the corollary to Proposition 1, to prove the existence of an $x \in X$ such that

(2.11)\[ u^* \in (T+J)(x). \]

Take any $\alpha \geq \alpha_0$ such that $\alpha > \|u^*\|$. Since $T + B_\alpha$ is maximal by hypothesis, there exists by Proposition 1 a certain $x \in X$ such that

$$ u^* \in (T + B_\alpha + J)(x) = (T + J)(x) + B_\alpha(x). $$

By the definition of $B_\alpha$, this means that

(2.12)\[ u^* \in (T + J)(x) + \lambda J(x) = (T + (1 + \lambda)J)(x), \]

where $\|x\| \leq \alpha$, and $\lambda$ is some nonnegative number, taken to be 0 if $\|x\| < \alpha$. We shall show that indeed $\|x\| < \alpha$, so that (2.12) reduces to (2.11) as desired. According to (2.12), there exists an $x^* \in T(x)$ such that

$$ u^* = x^* + (1 + \lambda)J(x). $$

In terms of this $x^*$, we have

$$ \langle x, u^* \rangle = \langle x, x^* \rangle + (1 + \lambda)\langle x, J(x) \rangle, $$

where $\langle x, x^* \rangle \geq 0$ by the monotonicity of $T$ and the fact that $0 \in T(0)$. It follows by (2.1) that

$$ (1 + \lambda)\|x\|^2 = (1 + \lambda)\langle x, J(x) \rangle \leq \langle x, u^* \rangle \leq \|x\| \cdot \|u^*\|, $$

and hence that

$$ \|x\| \leq (1 + \lambda)^{-1}\|u^*\| < (1 + \lambda)^{-2}\alpha \leq \alpha. $$

3. **Proofs of the main results.**

**Proof of Theorem 1.** Since assumptions (a) and (b) in Theorem 1 are equivalent by [14, Theorem 1], as already pointed out, we need only consider the case of assumption (a). We shall suppose, to begin with, that $D(T_\alpha)$ is also a bounded subset of $X$. Subsequently we shall prove, using Proposition 3, that this boundedness assumption is unnecessary. It will be assumed, of course, that the norm on $X$ which we work with has the special properties described at the beginning of §2.

Translating $T_1$ and $T_2$ by a common amount if necessary, and subtracting a constant mapping from $T_1$, we can assume that

(3.1)\[ 0 \in T_1(0), \quad 0 \in \text{int} D(T_2). \]
Let $J$ be the duality mapping defined above. We shall show that, for the monotone operator $T_1 + T_2$, $R(T_1 + T_2 + J)$ is all of $X^*$, and this will establish that $T_1 + T_2$ is maximal, according to the corollary to Proposition 1.

Given any $\bar{x}^* \in X^*$, we must show that $\bar{x}^* \in R(T_1 + T_2 + J)$. Subtracting a constant mapping from $T_2$ if necessary, we can reduce the argument to the case where $\bar{x}^* = 0$. Thus we need only show the existence of an $x \in X$ such that

$$ (3.2) \quad 0 \in (T_1 + T_2 + J)(x). $$

Now $x$ satisfies (3.2) if and only if there exists an $x^* \in X^*$ such that

$$ (3.3) \quad -x^* \in (T_1 + (1/2)J)(x) \quad \text{and} \quad x^* \in (T_2 + (1/2)J)(x). $$

Define the mappings $S_1$ and $S_2$ from $X^*$ to $X$ by

$$ (3.4) \quad S_1(x^*) = -(T_1 + (1/2)J)^{-1}(-x^*), $$

$$ (3.5) \quad S_2(x^*) = (T_2 + (1/2)J)^{-1}(x^*). $$

The existence of an $x$ and $x^*$ satisfying (3.3) is then equivalent to the existence of an $x^*$ satisfying

$$ (3.6) \quad 0 \in S_1(x^*) + S_2(x^*). $$

Therefore, to prove the existence of an $x$ satisfying (3.2), it suffices to prove that

$$ (3.7) \quad 0 \in R(S_1 + S_2). $$

To do this, we observe from Proposition 1 that $S_1$ and $S_2$ are single-valued maximal monotone operators, continuous from the strong topology of $X^*$ to the weak topology of $X$, such that

$$ (3.8) \quad D(S_1) = X^* = D(S_2). $$

Hence $S_1 + S_2$ is a single-valued monotone operator, continuous from the strong topology to the weak topology, such that $D(S_1 + S_2) = X^*$, and this implies by Browder [3, Theorem 1.2] that $S_1 + S_2$ is maximal. Since $J(0) = 0$, we have

$$ (3.9) \quad 0 \in (T_1 + (1/2)J)(0) $$

by (3.1), and consequently $0 \in S_1(0)$. Therefore

$$ (3.10) \quad \langle S_1(x^*), x^* \rangle \geq 0, \quad \forall \ x^* \in X^*, $$

by the monotonicity of $S_1$. Furthermore, $R(S_2) = D(T_2 + (1/2)J) = D(T_2)$, so that $R(S_2)$ is a bounded set by our initial assumption and, by (3.1),

$$ (3.11) \quad 0 \in \text{int} \ R(S_2). $$

We shall show that these properties of $R(S_2)$ imply the existence of an $\alpha > 0$ such that

$$ (3.12) \quad \langle S_2(x^*), x^* \rangle \geq 0 \quad \text{whenever} \quad \|x^*\| > \alpha. $$
This will establish (3.7) as desired, via Proposition 2, since by (3.10) and (3.12) we will have
\[ \langle (S_1 + S_2)(x^*), x^* \rangle \geq 0 \text{ whenever } \|x^*\| > \alpha. \]

The proof that (3.12) holds for some \( \alpha > 0 \) proceeds as follows. For any \( x^* \) and \( y^* \) in \( X^* \), we have
\[ \langle S_2(x^*) - S_2(y^*), x^* - y^* \rangle \geq 0 \]
by the monotonicity of \( S_2 \), in other words
\[ \langle S_2(x^*), x^* \rangle \geq \langle S_2(y^*), x^* \rangle + \langle S_2(x^*) - S_2(y^*), y^* \rangle. \]

Since \( R(S_2) \) is bounded in \( X \), \( R(S_2) \) is contained in a certain ball of radius \( \alpha_1 > 0 \) about the origin, and hence
\[ |\langle S_2(x^*) - S_2(y^*), y^* \rangle| \leq 2\alpha_1 \|y^*\| \]
in (3.13). On the other hand, (3.11) implies by [14, Theorem 1] that \( S_2^{-1} \) is locally bounded at 0. Thus there exist \( \epsilon > 0 \) and \( \alpha_2 > 0 \) such that
\[ \|S_2(y^*)\| \leq \alpha_2 \Rightarrow \{y \mid \|y\| \leq \epsilon\}. \]

From (3.13) and (3.14), we have
\[ \langle S_2(x^*), x^* \rangle \geq \langle S_2(y^*), x^* \rangle - 2\alpha_1 \alpha_2 \]
for every \( y^* \) with \( \|y^*\| \leq \alpha_2 \), so that by (3.15)
\[ \langle S_2(x^*), x^* \rangle \geq \sup_{\|y^*\| \leq \alpha_2} \{ \langle y, x^* \rangle - 2\alpha_1 \alpha_2 \} = \epsilon \|x^*\| - 2\alpha_1 \alpha_2. \]

The latter expression is nonnegative when \( \|x^*\| \geq 2\alpha_1 \alpha_2 / \epsilon \), and therefore (3.12) holds, as claimed, for \( \alpha \geq 2\alpha_1 \alpha_2 / \epsilon \).

The argument that we have given so far proves that Theorem 1 is valid under the additional hypothesis that \( R(S_2) \) is bounded. We shall show now that this narrower version of Theorem 1 implies the general version. Let \( T_1 \) and \( T_2 \) be maximal monotone operators such that
\[ \langle D(T_1) \cap \text{int} \ D(T_2) \neq \emptyset, \]
where \( D(T_2) \) is not necessarily bounded. Translating the domains of \( T_1 \) and \( T_2 \) if necessary, we can assume that the origin belongs to the intersection (3.16). For each \( \alpha > 0 \), the maximal monotone mapping \( B_\alpha \) described in §2 then satisfies \( D(T_2) \cap \text{int} \ D(B_\alpha) \neq \emptyset \), and \( D(B_\alpha) \) is bounded. The monotone operator \( T_2 + B_\alpha \) is therefore maximal by the narrower version of Theorem 1. Since
\[ D(T_2 + B_\alpha) = \{ x \in D(T_2) \mid \|x\| \leq \alpha \}, \]
and the origin belongs to the intersection (3.16), we have \( D(T_1) \cap \text{int} \ D(T_2 + B_\alpha) \)
≠ ∅, where \(D(T_2 + B_α)\) is again bounded. Thus the mapping \(T_1 + (T_2 + B_α) = (T_1 + T_2) + B_α\) is a maximal monotone operator for every \(α > 0\) by the narrower version of Theorem 1, and we may conclude from Proposition 3 that \(T_1 + T_2\) is maximal. This proves Theorem 1 in the general case.

**Proof of Theorem 2.** Translating \(T_1\) and \(T_2\) by a common amount if necessary, we can suppose that

\[
0 \in \text{ri } D(T_1) \cap \text{ri } D(T_2),
\]

so that the affine hulls of \(D(T_1)\) and \(D(T_2)\) are certain subspaces \(L_1\) and \(L_2\) of \(X\), respectively. Let \(L_0 = L_1 \cap L_2\), and for \(i = 0, 1, 2\) let

\[
L_i^\perp = \{x^* \in X^* \mid \langle x, x^* \rangle = 0, \forall x \in L_i\},
\]

\[
P_i(x) = L_i^\perp \quad \text{if } x \in L_i,
\]

\[
P_i(x) = \emptyset \quad \text{if } x \notin L_i.
\]

Each \(P_i\) is a maximal monotone operator (the subdifferential of the indicator of \(L_i\)), and

\[
P_0 = P_1 + P_2 = P_0 + P_1 = P_0 + P_2.
\]

Given any \(x \in D(T_1), x^* \in T_1(x), z^* \in L_1^\perp\), we have \(\langle x - y, (x^* + z^*) - y^* \rangle = \langle x - y, x^* - y^* \rangle \geq 0\) whenever \(y \in D(T_1), y^* \in T(y)\), because \(T_1\) is a monotone operator with \(D(T_1) \subseteq L_1\), and this implies by the maximality of \(T_1\) that

\[
x^* + z^* \in T_1(x).
\]

Thus

\[
T_1 = T_1 + P_1.
\]

Similarly

\[
T_2 = T_2 + P_2,
\]

and it follows that

\[
T_1 + T_2 = T_1 + T_2 + P_1 + P_2 = (T_1 + P_0) + T_2.
\]

In view of (3.20) and (3.21), we can regard \(T_1\) and \(P_0\) in a natural way as maximal monotone operators from the space \(L_1\) to the quotient space \(X^*/L_1^\perp\), which may be identified with the dual \(L_1^\ast\) of \(L_1\). Theorem 1 is applicable to these mappings from \(L_1\) to \(L_1^\ast\), since by (3.17) the origin belongs to the intersection of \(D(P_0) = L_0\) and the interior, relative to \(L_1\), of \(D(T_1)\). Thus \(T_1 + P_0\) must be a maximal monotone operator from \(X\) to \(X^\ast\). Now we apply a similar argument to the space \(L_2\). Since (3.22) holds and \((T_1 + P_0) + P_2 = T_1 + P_0\), we can regard \(T_1 + P_0\) and \(T_2\) as maximal monotone operators from \(L_2\) to \(X^*/L_2^\perp\), which may be identified with \(L_2^\ast\). The interior of \(D(T_2)\) relative to \(L_2\) meets \(D(T_1 + P_0) = D(T_1) \cap L_2\) by (3.17), so \((T_1 + P_0) + T_2\) is maximal by Theorem 1. This means by (3.23) that \(T_1 + T_2\) is a maximal monotone operator from \(X\) to \(X^\ast\).
Proof of Theorem 3. As already mentioned in §1, $T_1$ is a maximal monotone operator, since it is the subdifferential of a certain closed proper convex function, namely the indicator of $K$ [12], [13]. Therefore $T_1 + T_2$ is, at all events, a monotone operator. Let $y \in X$ and $y^* \in X^*$ be such that

$$\langle x-y, x^*-y^* \rangle \geq 0 \quad \text{whenever } x^* \in T_1(x) + T_2(x),$$

or in other words

$$\langle x-y, x_1^* \rangle + \langle x-y, T_2(x)-y^* \rangle \geq 0 \quad \text{whenever } x \in K \text{ and } x_1^* \text{ is normal to } K \text{ at } x.$$ 

We shall demonstrate by a direct argument that

$$y^* \in T_1(y) + T_2(y), \quad \text{i.e. } y^* - T_2(y) \in T_1(y),$$

and this will prove that $T_1 + T_2$ is maximal.

If $x$ is any point of $K$ and $x_1^*$ is normal to $K$ at $x$, then $\lambda x_1^*$ is likewise normal to $K$ at $x$ for every $\lambda \geq 0$, so that by (3.25)

$$\lambda \langle x-y, x_1^* \rangle + \langle x-y, T_2(x)-y^* \rangle \geq 0, \quad \forall \lambda \geq 0.$$ 

This implies that $\langle x-y, x_1^* \rangle \geq 0$. Thus

$$\langle x-y, x_1^*-0 \rangle \geq 0 \quad \text{whenever } x_1^* \in T_1(x),$$

and since $T_1$ is a maximal monotone operator we may conclude that $0 \in T_1(y)$. Hence $y \in K$.

To complete the proof that (3.26) holds, i.e. that $y^* - T_2(y)$ is normal to $K$ at $y$, we need only show that

$$\langle u-y, y^*-T_2(y) \rangle \leq 0, \quad \forall u \in K.$$ 

Fix any $u \in K$, and let

$$x_\lambda = \lambda u + (1-\lambda)y, \quad 0 < \lambda < 1.$$ 

Since $y \in K$ and $K$ is convex, we have $x_\lambda \in K$. Therefore (3.25) holds for $x=x_\lambda$ and $x_1^*=0$, and we have

$$0 \leq \langle x_\lambda-y, T_2(x)-y^* \rangle = \lambda \langle u-y, T_2(x)-y^* \rangle = \lambda \langle u-y, T_2(x_\lambda)-T_2(y) \rangle - \lambda \langle u-y, y^*-T_2(y) \rangle.$$ 

This implies that

$$\langle u-y, y^*-T_2(y) \rangle \leq \langle u-y, T_2(x_\lambda)-T_2(y) \rangle, \quad 0 < \lambda < 1.$$ 

Since $T_2$ is hemicontinuous, $T_2(x_\lambda)$ converges in the weak* topology to $T_2(y)$ as $\lambda$ decreases to 0, and (3.27) must hold.

4. Applications. Theorems 1, 2 and 3 may be used to get new theorems asserting that $R(T_1 + T_2)$ is all of $X$, or that $0 \in R(T_1 + T_2)$, and so forth.
For example, Theorem 3 of Browder [6] leads to the following result, where a monotone operator $T: X \to X^*$ is said to be coercive if
\begin{equation}
\lim_{\alpha \to +\infty} (1/\alpha) \inf \{ \langle x, x^* \rangle \mid x^* \in T(x), \|x\| \geq \alpha \} = +\infty
\end{equation}
\((\inf \varnothing \text{ being } +\infty \text{ by convention}).

**Theorem 4.** Let $X$ be reflexive, and let $T_1$ and $T_2$ be monotone operators satisfying the hypothesis of Theorem 1 (or Theorem 2 or Theorem 3), such that $T_1 + T_2$ is coercive. Then $R(T_1 + T_2) = X^*$.

(In particular, $T_1 + T_2$ is coercive if $0 \in D(T_1)$ and $T_2$ is coercive, or vice versa. Also, $T_1 + T_2$ is coercive trivially if $L(T_1) \cap L(T_2)$ is bounded.)

**Proof.** The monotone operator $T = T_1 + T_2$ is maximal by Theorem 1 (or by Theorem 2 or Theorem 3, as the case may be), and since $T$ is also coercive we have $R(T) = X^*$ according to Browder [6, Theorem 3]. (Browder’s result assumes that the unit ball of $X^*$ is strictly convex and that $0 \in D(T)$. However, the strict convexity assumption can be avoided by giving the proof in terms of a duality mapping $J$ of the type employed in §2. This is permissible, since passage to an equivalent norm on $X$ does not alter the coerciveness of the operator $T$. The assumption that $0 \in D(T)$ can then be avoided by invoking Proposition 1 of the present paper in the proof in place of Browder’s Theorem 1.)

In the case where $T_1$ and $T_2$ satisfy the hypothesis of Theorem 3, Theorem 4 yields a result about variational inequalities proved independently by Browder [4] and Hartman-Stampacchia [8].

A condition for the existence of an $x$ satisfying
\begin{equation}
0 \in T_1(x) + T_2(x)
\end{equation}
can be obtained at once by combining Theorems 1, 2 and 3 with Proposition 2. In particular, taking $T_1$ or $T_2$ to be the normality operator associated with a convex set $K$, one obtains the following existence theorem for solutions to variational inequalities.

**Theorem 5.** Let $X$ be reflexive, let $K$ be a closed convex subset of $X$, and let $A: X \to X^*$ be a (possibly multivalued) monotone operator. Suppose there exist an $a \in K$ and an $\alpha > 0$ such that
\begin{equation}
\langle x - a, x^* \rangle \geq 0 \text{ whenever } x \in D(A) \cap K, \|x\| \geq \alpha, x^* \in A(x).
\end{equation}
Suppose also that one of the following five conditions is satisfied:
\begin{enumerate}
  \item[(a)] $D(A) \supseteq K$ and $A$ is single-valued and hemicontinuous on $K$, or
  \item[(b)] $A$ is maximal and $K \cap \text{int} D(A) \neq \emptyset$, or
  \item[(c)] $A$ is maximal and $D(A) \cap \text{int} K \neq \emptyset$, or
  \item[(d)] $A$ is locally bounded at some $x \in K \cap \text{cl} D(A)$ and maximal, or
  \item[(e)] $X$ is finite-dimensional, $A$ is maximal and
  \[ \text{ri} D(A) \cap \text{ri} K \neq \emptyset. \]
\end{enumerate}
Then the variational inequality for $A$ and $K$ has a solution, i.e. there exists at least one $x \in D(A) \cap K$ such that, for some $x^* \in A(x)$, $-x^*$ is normal to $K$ at $x$.

**Proof.** Replacing $K$ and $A$ by the translates $K' = K-a$ and $A'(x) = A(x+a)$ if necessary, we can reduce the theorem to the case where $a=0$. In terms of the normality operator $N$ for $K$, which has $D(N) = K$, the solutions to the variational inequality for $A$ and $K$ are simply the points $x$ such that

$$0 \in N(x) + A(x) = (N+A)(x).$$

Such a solution exists by Proposition 2, if the monotone operator $T = N + A$ is maximal, since condition (2.5) for $T$ is equivalent to condition (4.3) on $K$ and $A$ (when $0 = a \in K$). Each of the conditions (a), (b), (c), (d) and (e) is sufficient, in view of Theorems 1, 2 and 3, for $T$ to be maximal.

When the set $K$ is given by a system of convex inequality constraints,

$$K = \{ x \mid f_i(x) \leq 0, \ i = 1, \ldots, m \},$$

the normality condition in Theorem 5 can sometimes be expressed in terms of the subdifferentials $\partial f_i$ of the convex functions $f_i$ and certain Lagrange multipliers. In particular, there is the following result.

**Corollary.** Let $X$ be reflexive, and let $T : X \to X^*$ be a maximal monotone operator. Let $f_1, \ldots, f_m$ be continuous real-valued convex functions on $X$. Suppose there exist an $a \in X$ and an $\alpha > 0$ such that

$$a \in D(T) \quad \text{and} \quad f_i(a) < 0 \quad \text{for } i = 1, \ldots, m,$$

$$\langle x-a, x^* \rangle \geq 0 \quad \text{whenever } x \in D(T), \quad x^* \in T(x),$$

$$\|x\| > \alpha \quad \text{and} \quad f_i(x) \leq 0 \quad \text{for } i = 1, \ldots, m.$$

Then there exist real numbers $\lambda_1, \ldots, \lambda_m$ (Lagrange multipliers) and an $x \in X$ such that

$$\lambda_i \geq 0, \quad f_i(x) \leq 0, \quad \lambda_i f_i(x) = 0, \quad i = 1, \ldots, m,$$

$$0 \in T(x) + \lambda_1 \partial f_1(x) + \cdots + \lambda_m \partial f_m(x).$$

**Proof.** For $K$ as in (4.4), we have $a \in D(T) \cap \text{int } K$ by (4.5), so that the hypothesis of Theorem 5 is satisfied under condition (c). The corollary then follows from the fact that (since the inequality system $f_i < 0, \ i = 1, \ldots, m$, can be satisfied) the normal cone to $K$ at a point $x \in K$ is the union of $\lambda_1 \partial f_1(x) + \cdots + \lambda_m \partial f_m(x)$ over all coefficients $\lambda_i$ such that $\lambda_i \geq 0$ for indices $i$ such that $f_i(x) = 0$ and $\lambda_i = 0$ for indices $i$ such that $f_i(x) < 0$. For the proof of the latter fact, see Rockafellar [11, p. 86]. (The argument in [11] concerns the case where $f_1, \ldots, f_m$ are Gateaux differentiable, but it is easily extended to the general case.)

**Remark.** When certain of the functions $f_i$ are actually affine (i.e. linear-plus-a-constant), the corresponding conditions $f_i(a) < 0$ in (4.5) may be weakened to
$f(a) \leq 0$, provided that the condition $a \in D(T)$ is strengthened at the same time to $a \in \text{int } D(T)$. This follows by the argument given in [11, p. 87]. With this modification, the corollary may be applied to cases where the definition of $K$ involves constraints of the form $\langle x, b \rangle = \beta$, where $b \in X^*$, since such a constraint can always be re-expressed as a pair of affine inequality constraints:

$$f_1(x) = \langle x, b \rangle - \beta \leq 0, \quad f_2(x) = \beta - \langle x, b \rangle \leq 0.$$ 

Observe that, according to (4.8) the “solution” $x$ whose existence is asserted in the corollary is in particular a solution to:

$$(4.9) \quad 0 \in S(x), \quad \text{where } S = T + \lambda_1 \partial f_1 + \cdots + \lambda_n \partial f_n.$$ 

Moreover, $S$ is a maximal monotone operator by Theorem 1, since the subdifferentials $\partial f_i$ are maximal monotone operators with $D(\partial f_i) = X$. (A nonnegative multiple of a maximal monotone operator with effective domain $X$ is trivially another maximal monotone operator.) In particular, suppose in the corollary that $T$ is single-valued on $D(T)$, and that each $f_i$ is actually Gâteaux differentiable, so that the subdifferentials $\partial f_i$ reduce to single-valued gradient mappings $\nabla f_i$. Then $S$ is a single-valued maximal monotone operator with $D(S) = D(T)$, and (4.9) becomes an equation:

$$(4.10) \quad 0 = S(x) = T(x) + \lambda_1 \partial f_1(x) + \cdots + \lambda_n \partial f_n(x).$$ 

The Lagrange multipliers $\lambda_i$ thus make it possible sometimes to reduce variational inequalities to operator equations of a simpler sort, which can be useful of course in the analysis of the solutions $x$, at least in cases where $T$ is a differential or integral operator whose properties are well understood.
