CLASSIFICATION OF GENERALIZED WITT ALGEBRAS
OVER ALGEBRAICALLY CLOSED FIELDS(*)

BY
ROBERT LEE WILSON

Abstract. Let \( \Phi \) be a field of characteristic \( p > 0 \) and \( m, n_1, \ldots, n_m \) be integers \( \geq 1 \). A Lie algebra \( W(m : n_1, \ldots, n_m) \) over \( \Phi \) is defined. It is shown that if \( \Phi \) is algebraically closed then \( W(m : n_1, \ldots, n_m) \) is isomorphic to a generalized Witt algebra, that every finite-dimensional generalized Witt algebra over \( \Phi \) is isomorphic to some \( W(m : n_1, \ldots, n_m) \), and that \( W(m : n_1, \ldots, n_m) \) is isomorphic to \( W(s : n_1, \ldots, n_s) \) if and only if \( m = s \) and \( n_i = n_{\sigma(i)} \) for \( 1 \leq i \leq m \) where \( \sigma \) is a permutation of \( \{1, \ldots, m\} \). This gives a complete classification of the finite-dimensional generalized Witt algebras over algebraically closed fields. The automorphism group of \( W(m : n_1, \ldots, n_m) \) is determined for \( p > 3 \).

Introduction. Let \( \Phi \) be a field of characteristic \( p > 0 \). Kaplansky [5] (generalizing earlier definitions by Witt [1], Zassenhaus [11] and Jacobson [2]) has defined a family of Lie algebras over \( \Phi \) in the following manner: Let \( I = \{i, j, \ldots\} \) be a set of indices, \( \mathcal{G} \) be a total additive group of functionals on \( I \) with values in \( \Phi \), and \( \mathcal{L} \) be a vector space with basis \( I \times \mathcal{G} \). Define a bilinear multiplication in \( \mathcal{L} \) by

\[
[(i, \sigma), (j, \tau)] = \tau(i)(j, \sigma + \tau) - \sigma(j)(i, \sigma + \tau).
\]

It is easily seen that \( \mathcal{L} \) is a Lie algebra. Following Ree [7] we will call such algebras generalized Witt algebras.

The problem we consider in this paper is the classification of the finite-dimensional generalized Witt algebras over algebraically closed fields. The study of this problem was begun by Ree [7] who showed that generalized Witt algebras over algebraically closed fields are isomorphic to certain algebras of derivations. (We state this result in detail in §2.) We give a complete solution to this problem by constructing for any field \( \Phi \) of characteristic \( p > 0 \) and any integers \( m, n_1, \ldots, n_m \geq 1 \) a Lie algebra \( W(m : n_1, \ldots, n_m) \) over \( \Phi \) and proving the following theorem (which was announced in [10]):

Theorem 1. Let $\Phi$ be an algebraically closed field of characteristic $p > 0$. Then
(a) $W(m : n_1, \ldots, n_m)$ is isomorphic to a generalized Witt algebra.
(b) Every finite-dimensional generalized Witt algebra over $\Phi$ is isomorphic to some
$W(m : n_1, \ldots, n_m)$.
(c) The algebras $W(m : n_1, \ldots, n_m)$ and $W(s : r_1, \ldots, r_s)$ are isomorphic if and
only if $m = s$ and $r_i = n_{\sigma(i)}$ for $1 \leq i \leq m$ where $\sigma$ is a permutation of $\{1, \ldots, m\}$.

The algebras $W(m : n_1, \ldots, n_m)$ have been studied by Kostrikin and Šafarevič
[6] who have proved a statement equivalent to (a). The conclusion in (c) that
$m = s$ is due to Ree [7, Theorem 12.14].

The definition of $W(m : n_1, \ldots, n_m)$ is given in §1. The proof of Theorem 1 is
contained in §§2 and 3. In §4 the automorphism group of $W(m : n_1, \ldots, n_m)$ is
determined for $p > 3$.

Since several families of nonclassical simple Lie algebras may be defined as
subalgebras of generalized Witt algebras (e.g., [4]), the results of this paper are of
considerable use in the study of nonclassical simple Lie algebras. In particular,
they can be used to prove that all the finite-dimensional nonclassical simple Lie
algebras listed in [9, pp. 105–110] are of Cartan type (in the sense of [6] or [10])
thus effecting a considerable simplification in the description of the known finite-
dimensional nonclassical simple Lie algebras. This topic will be treated in a later
paper.

1. Definitions. We begin by defining a family of associative algebras over an
arbitrary field $\Phi$. Let $C$ denote the complex numbers, $Z$ the integers and $N$ the
nonnegative integers. Let $A(m)$ be the set of $N$ valued functions on $\{1, \ldots, m\}$.
Define $e_i \in A(m)$ by $e_i(j) = \delta_{ij}$. For $\alpha, \beta \in A(m)$ define $a! = \prod a(i)$!, $|\alpha| = \sum a(i)$ and
$C(\alpha, \beta) = \prod C(\alpha(i), \beta(i))$ (where $C(r, s)$ is the binomial coefficient $r!/s!(r-s)!$). Let
$A(m) = C[x_1, \ldots, x_m]$. For $\alpha \in A(m)$ define $x^\alpha = (\prod x_i^{a(i)})a! \in A(m)$. Then
\begin{equation}
    x^\alpha x^\beta = C(\alpha + \beta, \beta)x^{\alpha + \beta}.
\end{equation}

Set $A(m) = \{\sum a_\alpha x^{\alpha} \mid a_\alpha \in Z\} \subseteq A(m)$ where the summation extends over all $\alpha \in A(m)$
and infinite sums are allowed. Then $A(m)$ is a $Z$-subalgebra of $A(m)$. For any
field $\Phi$ define $A(m) = A(m) \otimes_\Phi$. Then $A(m)$ is an associative algebra over $\Phi$.
Denoting $x^a \otimes 1$ by $x^a$ we see that multiplication in $A(m)$ satisfies (1.1). For
$1 \leq i \leq m$ denote $x^e_i$ by $x_i$.

For $0 \neq \sum a_\alpha x^{\alpha} \in A(m)$ define $|\sum a_\alpha x^{\alpha}| = \min \{|\alpha| \mid a_\alpha \neq 0\}$. Define $|0| = \infty$ and set
$A(m)_i = \{x \in A(m) \mid |x| \geq i + 1\}$. Then $A(m)$ is a topological algebra with
$\{A(m)_i \mid i \geq -1\}$ as a base of neighborhoods of $0$. Define $A(m)$ to be the subalgebra
of $A(m)$ consisting of all finite linear combinations of $\{x^\alpha \mid \alpha \in A(m)\}$. Then $A(m)$
is dense in $A(m)$. For any subalgebra $A$ of $A(m)$ define $A_i = A \cap A(m)_i$ for all
$i \in N$.

We now define a sequence of divided power operators on $A(m)$. These are the
analogues of the mappings $x \to x^r/r!$ in $A(m)$.
Lemma 1. There is a unique sequence of continuous mappings \( y \rightarrow y^{(r)} \) (\( r \in \mathbb{N} \)) of \( \mathcal{A}(m)_0 \) into \( \mathcal{A}(m) \) satisfying:

1. \( x^{(0)} = 1 \) for all \( x \in \mathcal{A}(m)_0 \).
2. \( (x^a)^{(r)} = \left( \frac{(ra)!}{(a!)^r} \right)x^a \) for all \( a \in A(m) \) such that \( a \neq 0 \) and all \( r \in \mathbb{N} \).
3. \( (ax)^{(r)} = a^{(r)}x^{(r)} \) for all \( a \in \Phi \), \( x \in \mathcal{A}(m)_0 \) and \( r \in \mathbb{N} \).
4. \( (x+y)^{(r)} = \sum_{r_1=0}^{r} x^{(r_1)}y^{(r-r_1)} \) for all \( x, y \in \mathcal{A}(m)_0 \) and all \( r \in \mathbb{N} \).

**Proof.** For the coefficient in (1.3) to be interpreted as an element of \( \Phi \) it must be an integer. Hence we first show that if \( 0 \neq a \in A(m) \) and \( r \in \mathbb{N} \) then \( (ra)!/(a!)^r \in \mathbb{Z} \). Since \( 0 \neq a \) we may suppose without loss of generality that \( \alpha(1) \neq 0 \). Then \( (ra)!/(a!)^r! \) is the product of \( \alpha(1)^r \) and \( \prod_{i=2}^{m} \left\{ \frac{(ra(i))!}{(a(i)!)^r} \right\} \). Now it suffices to show that each factor is an integer, i.e., if \( r, b \in \mathbb{N} \) then \( (rb)!/(b!)^r \in \mathbb{Z} \) and if \( b \geq 1 \) then \( (rb)!/(b!)^r \in \mathbb{Z} \). But this is immediate from the fact that \( (rb)!/(b!)^r = \prod_{j=1}^{r} C(jb, b) \) together with the observation that if \( b \neq 0 \) then \( C(jb, b) = jC(jb-1, b-1) \).

Now (1.2)—(1.5) define a unique sequence of maps \( y \rightarrow y^{(r)} \) of \( \mathcal{A}(m)_0 \) into \( \mathcal{A}(m) \). Since \( \mathcal{A}(m) \) is dense in \( \mathcal{A}(m) \) these can be uniquely extended to continuous maps of \( \mathcal{A}(m)_0 \) into \( \mathcal{A}(m) \).

Following Kostrikin and Šafarevič [6, p. 256] we call a derivation \( D \) of \( \mathcal{A}(m) \) special if

\[ y^{(r)}D = (yD)^{(r-1)} \quad \text{for all } y \in \mathcal{A}(m)_0 \text{ and all } r \in \mathbb{Z}, \quad r \geq 1. \]

It is easily seen that the special derivations of \( \mathcal{A}(m) \) span a Lie subalgebra of the derivation algebra. We denote this subalgebra by \( W(m) \).

Now let \( \Phi \) be a field of characteristic \( p > 0 \). Let \( \mathbf{n} = (n_1, \ldots, n_m) \) be an \( m \)-tuple of integers \( \geq 1 \). Define \( A(m; \mathbf{n}) = \{ a \in A(m) \mid a(i) < p^{n_i} \text{ for } 1 \leq i \leq m \} \). Now if \( a, \beta \in A(m; \mathbf{n}) \) and \( a + \beta \notin A(m; \mathbf{n}) \) then \( p \mid C(a + \beta, a) \). Thus \( \mathcal{A}(m; \mathbf{n}) = \langle x^a \mid a \in A(m; \mathbf{n}) \rangle \) is a subalgebra of \( \mathcal{A}(m) \). Define \( W(m; \mathbf{n}) \) to be the stabilizer of \( \mathcal{A}(m; \mathbf{n}) \) in \( W(m) \).

From (1.1) and (1.3) we see that \( \{ x_i \mid 1 \leq i \leq m \} \) generates \( \mathcal{A}(m)_0 \) under algebra operations and divided power operations. Thus (1.6) shows that if \( D \) is a special derivation satisfying \( x_iD = 0 \) for \( 1 \leq i \leq m \) then \( D = 0 \). Define derivations \( D_1, \ldots, D_m \) of \( \mathcal{A}(m) \) by

\[ x^\beta D_i = x^\beta x^{-\epsilon_i} \]

(where we set \( x^\phi = 0 \) for \( \beta \notin A(m) \)). It is easily seen that if \( a_1, \ldots, a_m \in \mathcal{A}(m) \) (respectively \( \mathcal{A}(m; \mathbf{n}) \)) then \( \sum D_i a_i \in W(m) \) (respectively \( W(m; \mathbf{n}) \)). For any \( D \in W(m) \) we have \( x_i(D - \sum_{i=1}^{m} D_i(x_iD)) = 0 \) for \( 1 \leq i \leq m \). Hence \( D = \sum D_i(x_iD) \). This proves the following lemma (due to Kostrikin and Šafarevič [6]).

**Lemma 2.** \( W(m) \) is a free \( \mathcal{A}(m) \) module with basis \( \{ D_1, \ldots, D_m \} \) and \( W(m; \mathbf{n}) \) is a free \( \mathcal{A}(m; \mathbf{n}) \) module with basis \( \{ D_1, \ldots, D_m \} \).

It is easily seen that the restriction map \( D \rightarrow D|\mathcal{A}(m; \mathbf{n}) \) is an isomorphism of \( W(m; \mathbf{n}) \) into \( \text{Der} (\mathcal{A}(m; \mathbf{n})) \). Thus we may, when necessary, regard \( W(m; \mathbf{n}) \) as a subalgebra of \( \text{Der} (\mathcal{A}(m; \mathbf{n})) \).
We see from (1.3)–(1.5) that $y^{(r)} = y'/r!$ for $r < p$. Hence every derivation of $A(m:1)$ is special so that $W(1:1)$ is the Witt algebra [1] and the algebras $W(m:1)$ are the Jacobson-Witt algebras [2]. If $E$ is an $m$-dimensional vector space and $F$ is the flag $E = E_0 \supseteq E_1 \supseteq \cdots$ then the algebra $W(F)$ of Kostrikin and Šafarevič [6, p. 261] is isomorphic to $W(m:n)$ where $\dim E_{i-1}$ is equal to the number of $i$ for which $n_i \geq j$.

Using (1.1) and (1.7) we see that multiplication in $W(m:n)$ is defined by bilinearity and

$$[D_i \alpha^a, D_j \alpha^b] = D_i \alpha^{a+\beta - e_i} C(\alpha + \beta - e_i, \beta) - D_j \alpha^{a+\beta - e_j} C(\alpha + \beta - e_j, \alpha).$$

The binomial coefficients may be evaluated using the following remark:

If $u = \sum_{i=0}^n u_i p^i$ and $v = \sum_{i=0}^n v_i p^i$ then

$$C(u+v, u) \equiv \prod_{i=0}^n C(u_i + v_i, u_i) \pmod{p}.$$ 

(For if we set $\bar{u} = \sum_{i=0}^n u_i ((p^i - 1)/(p - 1))$ it is easily seen that $u!p^{\bar{u}} \equiv (-1)^{\bar{u}} u_0! \cdots u_n! \pmod{p}$.) Defining $\bar{v}$ similarly in terms of the $v_i$ and $(u+v)^-$ similarly in terms of the $u_i + v_i$ we see that $\bar{u} + \bar{v} = (u+v)^-$ from which (1.9) follows.)

We will have occasion to use the following special cases of (1.8) and (1.9):

$$[D_i \alpha^a, D_j] = D_i \alpha^{a-e_i}.$$
$$[D_i \alpha^a, D_j \alpha^b] = D_i \alpha^a(\alpha(j) - \delta_{ij}).$$

We will also use the following properties of binomial coefficients:

If $C(r+s-1, r) \equiv 0 \pmod{p}$ for all $r$, $0 < r < s$,

then $s = p^w$ for some $w \in \mathbb{Z}$.

If $C(s+r-1, r) - C(s+r-1, r-1) \equiv -1 \pmod{p}$

for all $r$, $0 < r < s$, then $s = p^w$ for some $w \in \mathbb{Z}$.

To prove (1.12) write $s = \sum s_i p^i$ where $0 \leq s_i < p$ for all $i$. If $s = 1$ the result holds.

If $s > 1$ then $C(s, 1) \equiv 0 \pmod{p}$ so by (1.9) $s_0 = 0$. Similarly we see that if $s_0 = s_1 = \cdots = s_{i-1} = 0$ then either $s = p^i$ or $s_i = 0$. This proves (1.12). The proof of (1.13) is similar.

2. Proof of Theorem 1. Throughout this section we assume that $\Phi$ is an algebraically closed field of characteristic $p > 0$.

Let $A$ be a commutative associative algebra with unit over $\Phi$. A set $D = \{D_1, \ldots, D_m\}$ of derivations of $A$ is called a system if it is linearly independent over $\mathfrak{A}$ and if its $\mathfrak{A}$-span, denoted by $\mathfrak{L}(\mathfrak{A}:D)$, is a Lie subalgebra of the derivation algebra of $\mathfrak{A}$. A system $\{D_1, \ldots, D_m\}$ is said to be orthogonal if $[D_i, D_j] = 0$ for all $1 \leq i, j \leq m$. Two systems $D = \{D_1, \ldots, D_m\}$ and $E = \{E_1, \ldots, E_n\}$ are said to be equivalent if $\mathfrak{L}(\mathfrak{A}:D) = \mathfrak{L}(\mathfrak{A}:E)$. Clearly this occurs if and only if $m = n$ and $D_i = \sum E_j c_{ij}$ for $1 \leq i \leq m$ where $c_{ij} \in \mathfrak{A}$ for $1 \leq i, j \leq m$ and $\det(c_{ij})$ is a unit in $\mathfrak{A}$.
If $\mathfrak{g}$ is a subalgebra of $\mathfrak{g}$ containing $c_{ij}$ for $1 \leq i, j \leq m$ and $\det(c_{ij})^{-1}$ we say that the systems are equivalent over $\mathfrak{g}$. A derivation $D$ of $\mathfrak{g}$ is said to be normal if $a \in \mathfrak{g}$ and $aD = 0$ imply that $a \in \Phi$.

Denote by $1$ the $n$-tuple $(1, \ldots, 1)$. Let $y = (y_1, \ldots, y_n)$ be an $n$-tuple of elements of $\mathfrak{g}(m;1)$. For $a \in A(n;1)$ define $y^a = \prod_{i=1}^{n} (y^a_i!(a(i)!)$. We will call $y$ a system of standard generators for $\mathfrak{g}(n;1)$ if $y^a_i = 0$ for $1 \leq i \leq m$ and $\{y^a | a \in A(n;1)\}$ is a basis for $\mathfrak{g}(n;1)$. If $y$ is a system of standard generators for $\mathfrak{g}(n;1)$ define derivations $C_i(y)$ for $1 \leq i \leq n$ by

$$
y_iC_i(y) = \begin{cases} 0 & \text{if } j < i, \\ 1 & \text{if } j = i, \\ (y_1 \cdots y_{i-1})^{p-1} & \text{if } j > i. \end{cases}
$$

We now state some of Ree's results on generalized Witt algebras.

**Proposition 1.** (a) [7, §2] Any finite-dimensional generalized Witt algebra over $\Phi$ is isomorphic to some $L(\mathfrak{g};D)$.

(b) [7, Theorem 6.10] $L(\mathfrak{g};D)$ is isomorphic to a finite-dimensional generalized Witt algebra if and only if $\mathfrak{g}$ is finite dimensional and there exists an orthogonal system $\{E_1, \ldots, E_m\}$ equivalent to $D$ and satisfying the following conditions:

1. $\sum_{i=1}^{m} C_i(y)E_i = 0$ if $a \in \mathfrak{g}$ and $aE_i = \lambda a$ where $\lambda \in \Phi$ for all $i$, $1 \leq i \leq m$, then either $a = 0$ or $a$ is a unit in $\mathfrak{g}$.

2. If $a \in \mathfrak{g}$ and $aE_i = 0$ for all $i$, $1 \leq i \leq m$, then $a \in \Phi$.

(c) [7, Theorems 8.3, 9.2] If $D$ is an orthogonal system of derivations of $\mathfrak{g}$ satisfying (2.2) and (2.3) and if $\mathfrak{g}$ is finite dimensional then $\mathfrak{g} \cong \mathfrak{g}(n;1)$ for some $n$. Furthermore there exists an orthogonal system $E$ equivalent to $D$ such that $E_i$ is normal and nilpotent.

(d) [7, Theorems 8.3, 9.3] If $D$ is a normal and nilpotent derivation of $\mathfrak{g}(n;1)$ then there exists a system of standard generators $y$ of $\mathfrak{g}(n;1)$ such that $D = C_i(y)$. If $E$ is any derivation of $\mathfrak{g}(n;1)$ such that $[D, E] = 0$ then $E = \sum_{i=1}^{m} C_i(y)E_i$ where the $\gamma_i \in \Phi$.

(e) [7, Theorem 12.14] If $L(\mathfrak{g};D)$ and $L(\mathfrak{g};E)$ are isomorphic and finite dimensional where $D = \{D_1, \ldots, D_m\}$ and $E = \{E_1, \ldots, E_s\}$ are systems satisfying (2.2) and (2.3) then $m = s$.

(f) [8, Corollary 1.2] If $D = \{D_1, \ldots, D_m\}$ is a system of derivations of $\mathfrak{g}(n;1)$ satisfying (2.2) and (2.3) and if $p > 2$ then $\dim \text{Der} L(\mathfrak{g}(n;1);D) = mp^n + n - m$.

We will now apply these results to the proof of Theorem 1. By Lemma 2 we have $W(m;n) \cong L(\mathfrak{g}(m;n);D)$ where $D = \{D_1, \mathfrak{g}(m;n), \ldots, D_m, \mathfrak{g}(m;n)\}$ and the $D_i$ are defined by (1.7). Since $D$ is clearly an orthogonal system satisfying (2.2) and (2.3), Proposition 1(b) shows that $W(m;n)$ is isomorphic to a generalized Witt algebra. This proves Theorem 1(a).

For the proof of Theorem 1(b) we wish to find a system $E$ of derivations of $\mathfrak{g}(n;1)$ such that $W(m;n) \cong L(\mathfrak{g}(n;1);E)$. To do this set $l_1 = 0$, $l_i = \sum_{j=1}^{i-1} n_j$, for
2 \leq i \leq m$, and $n = \sum_{i=1}^{m} n_i$. Then if $y$ is a system of standard generators for $\mathfrak{W}(n:1)$ we see (using (1.1) and the fact that $\{x^a | a \in \mathfrak{W}(m:n)\}$ is a basis for $\mathfrak{W}(m:n)$) that the map $\tau: x^{n_k} \mapsto (-1)^k y_{i_k + k + 1}$ for $1 \leq i \leq m$ and $0 \leq k < n_i$ extends to an isomorphism of $\mathfrak{W}(m:n)$ onto $\mathfrak{W}(n:1)$. It is easily seen that the derivation $\tau^{-1} D \tau$ of $\mathfrak{W}(n:1)$ is equal to $C_{i_1 + 1}(y) - C_{i_1 + 1}(y)(y_{i_1 + 1} \cdots y_{i_1 + 1})$ for $1 \leq i < m$ and that $\tau^{-1} D \tau = C_{i_m + 1}(y)$. Thus $\{\tau^{-1} D_1 \tau, \ldots, \tau^{-1} D_m \tau\}$ is equivalent to $\{C_{i_1 + 1}(y) | 1 \leq i \leq m\}$ and hence $W(m:n)$ is isomorphic to $\mathfrak{L}(\mathfrak{W}(n:1): C_{i_1 + 1}(y), \ldots, C_{i_m + 1}(y))$.

Now by Proposition 1(a–c) any generalized Witt algebra is isomorphic to some $\mathfrak{L}(\mathfrak{W}(n:1): D)$ where $D$ is an orthogonal system of derivations satisfying (2.2) and (2.3). Thus Theorem 1(b) follows from

**Lemma 3.** If $D$ is an orthogonal system of derivations of $\mathfrak{W}(n:1)$ satisfying (2.2) and (2.3) then there exists a sequence of integers $0 = l_1 < l_2 < \cdots < l_m < n$ and a system of standard generators $y$ of $\mathfrak{W}(n:1)$ such that $D$ is equivalent to $\{C_{i_1 + 1}(y) | 1 \leq i \leq m\}$.

We will prove Lemma 3 in the next section.

We now determine the derivation algebra of $W(m:n)$. This result will be used in the proof of Theorem 1(c).

**Lemma 4.** Der $W(m:n)$ has basis $B_1(m:n) \cup B_2(m:n)$ where $B_1(m:n) = \{\text{ad } D x^a | 1 \leq i \leq m, a \in A(m:n)\}$, and $B_2(m:n) = \{\text{ad } D x^a | 1 \leq i \leq m, 1 \leq k < n\}$.

**Proof.** It is easily seen that $B_1(m:n) \cup B_2(m:n)$ consists of $mp^n + n - m$ linearly independent derivations of $W(m:n)$. If $p > 2$ Proposition 1(f) shows that $B_1(m:n) \cup B_2(m:n)$ must be a basis for Der $W(m:n)$. Thus it is necessary only to show that $B_1(m:n) \cup B_2(m:n)$ spans Der $W(m:n)$ when $p = 2$. (The proof we give for this does not, in fact, depend on $p$.) The proof has several steps.

(1) For $1 \leq i \leq m$ define $U_i$ to be the subspace of $W(m:n)$ spanned by $\{D_x x^a | 1 \leq j \leq m, a(i) = p^n - 1\}$. Then if $D$ is a derivation of $W(m:n)$ such that $D_j = 0$ for all $j < i$ there exists $D \in W(m:n)$ such that $D_j (D + \text{ad } D) = 0$ for all $j < i$ and $D_j (D + \text{ad } D) \in U_i$.

**Proof.** Let $D_j = \sum D_{x^a} a(k, a)$ where the summation extends over all $a \in A(m:n)$ and all $k \in \mathbb{Z}, 1 \leq k \leq m$. If $j < i$ then $0 = [D_j, D_i] = [D_j, D] = \sum D_{x^a} a(k, a)$ by (1.10)). Hence if $j < i$ and $a(j) \neq 0$ then $a(k, a) = 0$ for all $k$. Hence setting $D = \sum D_{x^a} a(k, a)$ where the summation extends over all $k$, $1 \leq k \leq m$, and over all $a \in A(m:n)$ such that $a(i) \neq p^n - 1$ gives the result.

(2) If $D$ is a derivation of $W(m:n)$ such that $D_j \in U_i$ then $D_j = 0$.

**Proof.** Let $D_j = \sum D_{x^a} a(k, a)$ as in (1). Note that $U_i \cap (W(m:n) \text{ ad } D) = 0$. Now by (1.11) we see that $[D_i x^a, D_i] = D_i [D, D] = \sum D_{x^a} a(k, a)$ in $U_i \cap (W(m:n) \text{ ad } D)$ so $D_j = [D_i x^a, D_j]$. Thus by (1.11) we see that

$$\sum D_{x^a} a(k, a) = \sum D_{x^a} a(k, a).$$

Thus $a(i) a(i, a) = 0$ for all $a$. Since $a(i, a) \neq 0$ implies that $a(i) \equiv -1 \pmod{p}$ this shows that $a(i, a) = 0$ for all $a$. If $m = 1$ this shows that $D_j = 0$ as required. If $m > 1$ and $j \neq i$
then \([D_i, D_j] = -[D_i, D_j, D_j] \in U_i \cap (W(m:n)) \text{ ad } D_i\) so \([D_i, D_j] = 0\). Similarly \([D_i, D_j, D_j] = 0\). Then (1.10) and (1.11) show that \(D_i [D_i, D_j] = 0\).

(3) Define a partial order on \(Z^m\) by \(r \leq n\) if and only if \(r_i \leq n_i\) for \(1 \leq i \leq m\). Then if \(\mathcal{D}\) is a derivation of \(W(m:n)\) there exists \(E\) in the linear span of \(B_1(m:n)\) such that \(W(m:r)(\mathcal{D} - E) \subseteq W(m:r)\) for all \(r \leq n\) and \(W(m:1)(\mathcal{D} - E) = 0\).

**Proof.** It is easily seen that if \(r \leq n\) then

\[W(m:r) = \{D \in W(m:n) | D(\text{ad } D_i)^{p_{ji}} = 0 \text{ for all } i, 1 \leq i \leq m\}.

Now by (1) and (2) we can find an inner derivation \(E_i\) such that \(D_i(\mathcal{D} - E_i) = 0\) for \(1 \leq i \leq m\). Then by the above characterization of \(W(m:r)\), \(W(m:r)(\mathcal{D} - E_i) \subseteq W(m:r)\). Since every derivation of \(W(m:1)\) is inner (by [2, Theorem 12]) we can find an inner derivation \(E_2\) of \(W(m:n)\) such that \(W(m:1)(\mathcal{D} - E_1 - E_2) = 0\). Since the linear span of \(B_1(m:n)\) is equal to the ideal of inner derivations of \(W(m:n)\), this proves (3).

(4) If \(\mathcal{D}\) is a derivation of \(W(m:n)\) such that \(W(m:1)\mathcal{D} = 0\) and if \(\beta \in A(m:n)\) is such that \(D_i x^j \mathcal{D} = 0\) for all \(j, 1 \leq j \leq m\), and all \(\alpha < \beta\) but \(D_i x^j \mathcal{D} \neq 0\) for some \(i\), then \(\beta = p_x e_k\) for some \(w, k \in \mathbb{Z}, 1 \leq k \leq m\) and \(D_i x^j \mathcal{D} = D_i a\) where \(a \in \Phi\).

**Proof.** If there exist \(l, k, 1 \leq l \neq k \leq m\), such that \(\beta(k) \neq 0\) and \(\beta(l) \neq 0\) then (taking \(k \neq i\))

\[(D_i x^j \mathcal{D} = [D_i x^j, D_k x^j] \mathcal{D} = 0),

a contradiction. Hence \(\beta = s e_k\) for some \(s, k \in \mathbb{Z}\). Now as \([D_i x^j, D_j] = 0\) for \(1 \leq j \leq m\), we have \((D_i x^j) \mathcal{D} = \sum D_i a_i\) where the \(a_i \in \Phi\). Then by (1.11) for \(1 \leq j \leq m\) we have \(-D_i a_i = [D_i a_i, D_j x_i] = [D_i x^j, D_j x_i] \mathcal{D} = \sum D_i a_i(\beta(j) - \delta_i j).\) Setting \(j = i\) we see that \(a_i = 0\) for all \(i \neq i\) whenever \(\beta(i) = 0\). But if \(\beta(i) \neq 0\) then \(\beta(i) = 0\) and setting \(j = i\) we again see that \(a_i = 0\). Hence \((D_i x^j) \mathcal{D} = D_i a\) where \(a \in \Phi\).

Now for \(0 < r < s\) we have

\[\begin{aligned}
&[D_i x^j, D_k x^j] \mathcal{D} = D_k x^j [D_i x^j, D_k x^j] \mathcal{D} = (D_k x^j)^{-1} D_i a C(s+r-1, r) - \delta_{ik} C(s+r-1, r-1)).
\end{aligned}

Also

\[\begin{aligned}
&D_i x^j, D_k x^j] \mathcal{D} = (D_i x^j) \mathcal{D} = -(D_i a) \delta_{ik}.
\end{aligned}

Thus \(C(s+r-1, r) - \delta_{ik} C(s+r-1, r-1) = -\delta_{ik}\) for \(0 < r < s\). Hence by (1.12) and (1.13) we see that \(s = p^n a\) as required.

(5) If \(\mathcal{D}\) is a derivation of \(W(m:n)\) and if \(W(m:r)\mathcal{D} = 0\) where \(1 \leq r < n\) and \(r_i < n_i\) for some \(i, 1 \leq i \leq m\), then there exists \(E\) in the linear span of \(B_2(m:n)\) such that \(W(m : r_i, 1 + 1, \ldots, r_m)(\mathcal{D} - E) = 0\).

**Proof.** If \(W(m : r_i, 1 + 1, \ldots, r_m)(\mathcal{D} - E) = 0\), we take \(E = 0\). If not there exists some \(\beta \in A(m : r_i, 1 + 1, \ldots, r_m)\) satisfying the hypotheses of (4). Then by (4) and the fact that \(W(m:r)(\mathcal{D} = 0)\) we see that \(\beta = p^{r_i} e_i\). Setting \(E = (ad D_i)^{p^{r_i}} a\) where \(a\) is as in (4) we have \((D_i x^{p^{r_i} e_i})(\mathcal{D} - E) = 0\). Now if \(j \neq i\) then \((D_j x^{p^{r_i} e_i})(\mathcal{D} - E) = [D_j x^{p^{r_i} e_i} x^{p^{r_i} e_i}][\mathcal{D} - E] = 0\). Hence \(W(m : r_i, 1 + 1, \ldots, r_m)(\mathcal{D} - E) = 0\) as required.
Lemma 4 now follows from (3) and (5) by induction on $n$.

We now prove Theorem 1(c). If $r_i = n_{a(i)}$ for $1 \leq i \leq m$ where $\sigma$ is a permutation of $\{1, \ldots, m\}$ then it is clear from the definitions that $W(m:n)$ and $W(m:r)$ are isomorphic. Conversely suppose that $W(m:n)$ and $W(s:r)$ are isomorphic. Then by Proposition 1(e) $m = s$. Since (by the preceding remark) we may rearrange the $n_i$ and the $r_i$, we may assume that $n_1 \geq n_2 \geq \cdots \geq n_n$ and $r_1 \geq r_2 \geq \cdots \geq r_m$. Now define

$$W(m:n)_{(0)} = \{ D \in W(m:n) \mid (ad D)^p \text{ is an inner derivation} \}$$

and for $i \in N$, $i > 0$, define

$$W(m:n)_{(i)} = \{ D \in W(m:n)_{(i-1)} \mid W(m:n)(ad D) \subseteq W(m:n)_{(i-1)} \}.$$

Then clearly $W(m:n)_{(0)} \cong W(m:r)_{(0)}$ for all $i \in N$. We will show that this implies that $r_i = n_i$ for $1 \leq i \leq m$ thus proving Theorem 1(c). The proof has several steps.

1. If $\sum D_i a_i \in W(m:n)$ define $|\sum D_i a_i| = \min |a_i|$. Then a derivation $\mathcal{D}$ of $W(m:n)$ is inner if and only if $|D\mathcal{D}| \geq |D| - 1$ for every $D \in W(m:n)$.

   Proof. From (1.8) we see that if $S$ is inner then $|\mathcal{D}S| \geq |D| - 1$ for all $D \in W(m:n)$. If $\mathcal{D}$ is an outer derivation then by Lemma 4 $\mathcal{D} = \sum_{i=1}^{n} \sum_{e=1}^{m} (ad a_i) (ad a_j) + \text{ad } E$ where the $a_i, a_j \in \Phi$, $E \in W(m:n)$ and some $a_{e_i} \neq 0$. Then setting $\mathcal{D} = D_1 x^{\delta_1, e_1}$ we have $|D\mathcal{D}| = 0 < p^2 - 1 = |D| - 1$.

2. $W(m:n)_{(0)} = \langle D_1 x^a \mid 1 \leq i \leq m, |a| \geq 1 - \delta_{1,n_i} \rangle$.

   Proof. By formula (ii), p. 188 of [3], if $\mathcal{L}$ is a Lie algebra over $\Phi$ and $a, b \in \mathcal{L}$ then $(ad (a + b))^p = (ad a)^p + (ad b)^p + \text{ad } c$ for some $c \in \mathcal{L}$. Hence $W(m:n)_{(0)}$ is a subspace of $W(m:n)$. Now if $|a| > 0$ and $D \in W(m:n)$ then (1.8) shows that $|D(ad D x^a)| \geq |D|$ for all $i$, $1 \leq i \leq m$. Hence $|D(ad D x^a)^p| \geq |D|$ for all $D \in W(m:n)$ so that by (1) $(ad D x^a)^p$ is an inner derivation for all $i$, $1 \leq i \leq m$. If $n_i = 1$ then $(ad D_i)^p = 0$ and hence is an inner derivation. Hence $W(m:n)_{(0)} \cong \langle D_i x^a \mid 1 \leq i \leq m, |a| \geq 1 - \delta_{1,n_i} \rangle$. If the inclusion is proper then, since $W(m:n)_{(0)}$ is a subspace, there is some $0 \neq D = \sum_{i=1}^{n_i} D_i a_i \in W(m:n)_{(0)}$ where the $a_i \in \Phi$. Then $(ad D)^p = \sum_{i=1}^{n_i} (ad D_i)^p a_i$ is an inner derivation, contradicting the linear independence of $B_i(m:n) \cup B_2(m:n)$.

3. For $k \in N$ define a subset $T_k \subseteq W(m:n)$ by $T_k = \langle D_i x^a \mid 1 \leq i \leq m, |a| \geq k + 1 - \delta_{1,n_i} \rangle$. If $n_i > 1$ then $T_{k+1} = \{ D \in T_k \mid W(m:n)(ad D) \subseteq T_k \}$ for all $k \in N$.

   Proof. It is immediate from (1.8) that

$$T_{k+1} \subseteq \{ D \in T_k \mid W(m:n)(ad D) \subseteq T_k \}$$

for all $k \in N$.

Conversely assume that $D = \sum D_i x^a a_i \in T_k$ and that $W(m:n)(ad D) \subseteq T_k$. Then in particular $D_j(ad D) \in T_k$ for all $j$, $1 \leq j \leq m$. Thus if $a_j(j) \neq 0$ and $a_{i,a} \neq 0$ we have $|a - e_j| \geq k + 1 - \delta_{1,n_i}$ so that $|a| \geq k + 2 - \delta_{1,n_i}$ and hence $D_i x^a \in T_{k+1}$. Thus $D \in T_{k+1}$ unless $a_{i,a} \neq 0$ for some $i$, $1 \leq i \leq m$. But then $(D_i x^a)(ad D) = \sum D_i x^a b_{i,a} \in T_k$ where $b_{1,0} \neq 0$. But this implies that $0 \geq k + 1 - \delta_{1,n_i} \geq 1$, a contradiction. Thus $D \in T_{k+1}$ proving (3).
(4) For $k \in \mathbb{N}$ define $A(k;m:n) = \{a \in A(m:n) \mid |a| = k\}$. Define $P(k;m:n)$ to be the cardinality of $A(k;m:n)$. Let $m = m' + m''$ where $m'$ is the number of $i$ such that $n_i > 1$. Then if $m' > 0$,

(2.4) $\dim W(m:n)_0/W(m:n)_{(0)} = m'$.

(2.5) $\dim W(m:n)_{(i)}/W(m:n)_{(i+1)} = m'P(i+1;m:n) + m''P(i;m:n)$ for all $i \in \mathbb{N}$.

**Proof.** Since $m' > 0$ it follows from (2) and (3) that $W(m:n)_{(i)} = T_i$ for all $i \in \mathbb{N}$. Since $T_i/T_{i+1}$ has basis

$$\{D_jx^a + T_{i+1} \mid 1 \leq j \leq m, |a| = i+1 - \delta_{1,n_j}\}$$

$$= \{D_jx^a + T_{i+1} \mid 1 \leq j \leq m', a \in A(i+1;m:n)\}$$

$$\cup \{D_jx^a + T_{i+1} \mid m' < j \leq m, a \in A(i;m:n)\},$$

the result is immediate.

(5) If $n_i > r_i$ and $n_j = r_j$ for $i < j \leq m$ then $P(p^i - 1;m:n) = P(p^i - 1;m:r)$ and $P(p^r;m:n) > P(p^r;m:r)$.

**Proof.** Clearly $A(p^i - 1;m:n) \supseteq A(p^i - 1;m:r)$. Let $a \in A(p^i - 1;m:n)$. Then if $j \geq i+1$ we have $a(j) < p^{i+1}$ and if $j \leq i$ we have $a(j) \leq |a| = p^i - 1 < p^i \leq p^{i+1}$. Hence $a \in A(p^i - 1;m:r)$. Thus $P(p^i - 1;m:n) = P(p^i - 1;m:r)$. Also $A(p^i;m:n) \supseteq A(p^i;m:r)$ but $p^i e_i \in A(p^i;m:n)$ and $p^i e_i \notin A(p^i;m:r)$ so $P(p^i;m:n) > P(p^i;m:r)$.

(6) $n_i = r_i$ for $1 \leq i \leq m$.

**Proof.** If not we may assume (interchanging the $n$’s and the $r$’s if necessary) that for some $i$ we have $n_i > r_i$ and $n_j = r_j$ for $i < j \leq m$. Then $n_i > 1$ so by (2) $W(m:n)$ is not restricted. Then $W(m:r)$ is not restricted since it is isomorphic to $W(m:n)$. Hence, again by (2), $r_i > 1$. Now we must have $\dim W(m:n)_0 = \dim W(m:r)_0$ for all $i \in \mathbb{N}$. Thus by (2.4) $m' = \text{(number of } i \text{ such that } n_i > 1 \text{)} = \text{(number of } i \text{ such that } r_i > 1 \text{)}. Then by (2.5)

$$m'P(p^r;m:n) + m''P(p^r - 1;m:n) = m'P(p^r;m:r) + m''P(p^r - 1;m:r).$$

But this contradicts (5).

This completes the proof of Theorem 1(c).

3. **Proof of Lemma 3.** In this section we prove Lemma 3 and thus complete the proof of Theorem 1. We continue to assume that $\Phi$ is an algebraically closed field of characteristic $p > 0$. We begin by showing that Lemma 3 is a consequence of the following weaker result:

**Lemma 3’.** If $D = \{D_1, \ldots, D_n\}$ is an orthogonal system of deviations of $\mathfrak{g}(n;1)$ satisfying (2.2) and (2.3) and if $m \geq 2$ then there exists an integer $l_2$, $0 < l_2 < n$, a system of derivations $E$ equivalent to $D$, and a system of standard generators $y$ of $\mathfrak{g}(n;1)$ such that

$$E_1 = C_1(y),$$

$$E_2 = C_{l_2+1}(y),$$

$$E_i = \sum_{j=l_2+2}^{n} C_j(y)\alpha_{ij} \quad \text{for } i > 2 \text{ where the } \alpha_{ij} \in \Phi.$$
Note that for \( m = 1 \) Lemma 3 is a restatement of Proposition 1(c), (d) and for \( m = 2 \) Lemmas 3 and 3' are identical. Assume that \( m > 2 \), that Lemma 3' holds and that Lemma 3 holds for \( m - 1 \). Let \( I_2, E, \) and \( y \) be as in the conclusion of Lemma 3'. Let \( B \) be the subalgebra of \( \mathfrak{A}(n:1) \) generated by \( \{y_i \mid i > I_2 \} \). Then for \( i \geq 2 \) \( E_i \) stabilizes \( B \) and \( \{E_2 B, \ldots, E_m B\} \) is a system of derivations of \( B \) satisfying (2.2) and (2.3). Hence by the induction assumption there exists a system of standard generators \( \{z_i \mid I_2 < i \leq n \} \) of \( B \), a system of derivations \( \{F_2, \ldots, F_m\} \) of \( B \) equivalent over \( B \) to \( \{E_2 B, \ldots, E_m B\} \), and a sequence of integers \( I_2 < I_3 < \cdots < I_m \) such that \( F_i = C_{i+1}(z) \) for \( 2 \leq i \leq m \). Thus \( F_1 = \sum (E_j B) c_{ij} \) for \( 2 \leq i \leq m \) where the \( c_{ij} \) are in \( B \). Setting \( G_i = \sum E_i c_{ij} \) for \( 2 \leq i \leq m \), \( z_i = y_i \) for \( 1 \leq i \leq I_2 \), and

\[
G_1 = E_1 + (G_2 - E_2) (z_2 \cdots z_{I_2})^{p-1}
\]

we see that \( G \) and \( z \) satisfy the conclusions of Lemma 3. Thus Lemma 3 is a consequence of Lemma 3'.

Now let \( D \) be as in Lemma 3'. Let \( S \) be the set of all pairs \((y, E)\) where \( y \) is a system of standard generators for \( \mathfrak{A}(n:1) \) and \( E \) is a system of derivations of \( \mathfrak{A}(n:1) \) equivalent to \( D \) and such that there is a sequence of integers \( 0 < I_2 < \cdots < I_m < n \) such that

\[
E_1 = C_1(y),
\]

\[
E_i = C_{i+1}(y) + \sum_{j=I_2+2}^{n} C_j(y) a_{ij} \quad \text{for } i \geq 2 \quad \text{where the } a_{ij} \text{ are in } \mathfrak{A}.
\]

By applying Proposition 1(c), (d) and the usual procedure for reducing a matrix to triangular form it is easily seen that \( S \) is nonempty.

For \((y, E) \in S\) define \( t(y, E) \) to be the \( m \)-tuple \((I_m, \ldots, I_2, I)\) where the \( I_i \) are as in (3.2) and \( I = \max \{i \mid I_2 + 1 \leq i \leq n, \alpha_{a,j}=0 \text{ whenever } I_2 + 2 \leq j \leq i \} \). Since \( I = n \) is equivalent to \( E_{a} = C_{I_2+1}(y) \) we see that Lemma 3' is equivalent to the statement that there exists some \((y, E) \in S\) such that \( t(y, E) = (I_m, \ldots, I_2, n) \). The proof of this statement has several steps.

1. (Ree [7, p. 535]) Let \((y, E) \in S\) and \( t(y, E) = (I_m, \ldots, I_2, I) \). Then if \( I \neq n \) there exists \((y', E') \in S\) with \( t(y, E) = t(y', E') \) and \( a_{I+1,I+1} = 1 \).

   Proof. Set \( y'_i = \lambda^{p^1} y_i \) and \( E'_i = E_i - \lambda^{p^1} \) where \( \lambda \) is a \((p^1-p^2)\) root of \( \alpha_{a_{I+1,I+1}} \).

2. For \( \alpha \in A(n:1) \) define \( \|\alpha\| = \sum a_{i} \alpha(i) p^1 - 1 \). If \( 0 \neq a = \sum a_{a} \alpha^{a} \) where \( y \) is a system of standard generators for \( \mathfrak{A}(n:1) \) and the \( a_{a} \in \Phi \) define \( \|\alpha\| = \max \{\|\alpha\| \mid a_{a} \neq 0\} \). Define \( \|0\| = -1 \). Let \( E \) be a derivation of \( \mathfrak{A}(n:1) \) such that \( \|y_i E\| = p^1 - 1 \) for all \( i, 1 \leq i \leq n \). Then \( \|f E\| = \|f\| - 1 \) for all \( f \in \mathfrak{A}(n:1), f \neq 0 \). Consequently \( E \) is a normal nilpotent derivation.

   Proof. Clearly \( \|\| \) satisfies:

   \( (3.3) \|fg\| \leq \|f\| + \|g\| \)

   \( (3.4) \|f\| > \|g\| \) then \( \|f + g\| = \|f\| \).

   Now \( y^0 E = \sum_{i=1}^{m} (y_i E) p^{i-1} \). By (3.3)

   \[
   \|(y_i E) p^{i-1}\| \leq \|\alpha\| - p^1 + (p^1 - 1) = \|\alpha\| - 1.
   \]
Furthermore equality holds if and only if \((y_1 \cdots y_{i-1})^{p-1}y^p = 0\), i.e., if and only if \(a(i) \neq 0\) and \(a(j) = 0\) for \(j < i\). Hence equality holds for exactly one \(i\) and so by (3.4) \(\|y^p\| = \|y\| - 1\). From this it is easily seen that \(\|fE\| = \|f\| - 1\) for all \(f \in \mathfrak{U}(n:1), f \neq 0\).

(3) If \(E\) is a normal derivation of \(\mathfrak{U}(n:1)\) and \(x_1, \ldots, x_r, y_1, \ldots, y_r\) are two sequences of elements of \(\mathfrak{U}(n:1)\) such that \(x_iE = y_iE, x_iE = (x_1 \cdots x_{i-1})^{p-1} - y_iE = (y_1 \cdots y_{i-1})^{p-1}\) for \(2 \leq i \leq r\), and \(x^p = y^p\) for \(1 \leq i \leq r\) then \(x_i = y_i\) for \(1 \leq i \leq r\).

**Proof.** Since \((x_1 - y_1)E = 0\) we have \(x_1 - y_1 \in \Phi\). Then \(0 = (x_i - y_i)^p = (x_1 - y_1)^p\) so \(x_1 = y_1\). If \(x_1 = y_1, \ldots, x_{i-1} = y_{i-1}\) then \((x_i - y_i)E = 0\) so as above \(x_i = y_i\).

(4) Let \(y\) and \(E\) be as in (2). Denote by \(\mathfrak{U}_0\) the subalgebra of \(\mathfrak{U}(n:1)\) generated by \(y, \ldots, y_r\). Then there exists a system of standard generators \(z\) of \(\mathfrak{U}(n:1)\) such that \(E = C_1(z)\) and \(z_i \in \mathfrak{U}_0\) for all \(i, 1 \leq i \leq n\).

**Proof.** By (2) \(E\) is a normal derivation of \(\mathfrak{U}(n:1)\). Moreover since \(\|y_iE\| = p^{i-1} - 1\) we have \(y_i \in \mathfrak{U}_0\) for all \(i, 1 \leq i \leq n\). Thus \(E\) restricts to a normal derivation of \(\mathfrak{U}_0\). Now by Proposition 1(d) there exists a system of standard generators \(z\) of \(\mathfrak{U}(n:1)\) such that \(E = C_1(z)\). Also there exists a system of standard generators \(\{t_1, \ldots, t_l\}\) of \(\mathfrak{U}_0\) such that \(E|\mathfrak{U}_0 = C_1(t)\). Then by (3) \(z_i = t_i \in \mathfrak{U}_0\).

(5) (Jennings and Ree [4, p. 193]) Let \(\{D_1, \ldots, D_m\}\) be an orthogonal system of derivations of \(\mathfrak{U}\). Let \(E_i = \sum_{k=1}^m D_k c_{ij}\) for \(1 \leq i \leq m\) where the \(c_{ij} \in \mathfrak{U}\). Then \([E_i, E_j] = 0\) if and only if \(c_{il}E_i = c_{lj}E_j\) for all \(l, 1 \leq l \leq m\).

**Proof.**

\[
[E_i, E_j] = \sum_{k=1}^m \sum_{l=1}^n [D_k c_{lk}, D_l c_{lj}] = \sum_{k=1}^m \sum_{l=1}^n D_k (c_{lk} D_l - D_l c_{lk}) = \sum_{k=1}^m D_k (c_{lk} E_j - c_{jk} E_i).
\]

(6) Let \((y, E) \in S, t(y, E) = (l_1, \ldots, l_2, l), l \neq n, \alpha_{2, l + 1} = 1, \) and \(l_m < l - l_2\). Then there exists a system of derivations \(F\) equivalent to \(E\) over \(\mathfrak{U}_0\) and a system of standard generators \(z\) of \(\mathfrak{U}(n:1)\) such that \((z, F) \in S\) and \(t(z, F) > t(y, E)\) in the lexicographic ordering.

**Proof.** For \(1 \leq i \leq m\) define \(G_i = \sum_{k=1}^m E_k c_{ij}\) where \(c_{11} = (y_{12} \cdots y_{ij})^{p-1}, c_{12} = (1 - (y_1 \cdots y_i)^{p-1}), c_{21} = 1, c_{22} = -(y_1 \cdots y_i)^{p-1}, c_{11} = y_{l+1} E_i\) for \(2 < i \leq m, c_{12} = -(y_1 \cdots y_i)^{p-1} c_{11}\) for \(2 < i \leq m\), and \(c_{ij} = \delta_{ij}\) for \(1 \leq i \leq m\) and \(2 < j \leq m\).

\[
\det (c_{ij}) \text{ is a unit so } G \text{ is a system of derivations equivalent to } E \text{ over } \mathfrak{U}_0 \text{ for all the } c_{ij} \in \mathfrak{U}_0.\text{ Moreover it is easily checked that } c_{ij} G_i = c_{ij} G_i \text{ for all } i, j, 1 \leq i, j \leq m.\text{ Hence by (5) } [G_i, G_j] = 0 \text{ for } 1 \leq i \leq m.
\]

We now show that \(G_1\) is normal and nilpotent. Set \(w_i = y_{i+1}, 1 \leq i \leq l - l_2, w_i = y_{l+1} \) for \(l - l_2 + 1 \leq i \leq l, \) and \(w_i = y_i\) for \(i > l\). Now it is easily checked that \(w_i G_1 = 1, w_i G_1 = (w_i \cdots w_{i-1})^{p-1} - (w_i \cdots w_{i-3})^{p-1} + \text{terms}\)
in \( w_1, \ldots, w_{i-1} \) of degree less than \((p-1)(i-1)\) for \( i > l \). Thus \( \lVert w_i G_1 \rvert = p^{-1} - 1 \) for all \( i, 1 \leq i \leq n \) (where \( \lVert \rVert \) is defined with respect to the system of standard generators \( w \)). Hence by (2) \( G_1 \) is a normal nilpotent derivation. Now by Proposition 1(d) there exists a system of standard generators \( z \) of \( \mathfrak{u}(n:1) \) such that \( C_i(z) = G_1 \). Also since \( [G_1, G_i] = 0 \) we have \( G_i = \sum_{j=1}^{n} C_j(z) \beta_{ij} \) for \( 2 \leq i \leq m \) where the \( \beta_{ij} \in \Phi \). Moreover by (3) for \( 1 \leq i \leq l - l_2 \) we have \( z_i = w_i = y_{l+1} \). Hence \( z_i G_2 = y_{l+1} G_2 = 0 \) for \( 1 \leq i \leq l - l_2 \). Thus \( \beta_{2j} = 0 \) for \( 1 \leq j \leq l - l_2 \). Now by applying the usual procedure for reduction to triangular form we obtain a system of derivations \( F \) such that \( (z, F) \in S \). If \( t(z, F) = (k_m, \ldots, k_2, k) \) then \( k_m \geq l - l_2 > l_m \). Hence \( t(z, F) > t(y, E) \) as required.

(7) Let \( y \) be a system of standard generators for \( \mathfrak{u}(n:1) \). If \( k > n \) set \( C_k(y) = 0 \). Then for \( 1 \leq i \leq n \) and \( j \in \mathcal{N} \), we have \( (C_i(y))^{j} = (-1)^j C_i(y) \).

Proof. It is easily seen that \( (C_i(y))^j \) and \( -C_{i+1}(y) \) agree on \( y \) and hence are equal. The general result follows by induction on \( j \).

(8) The conclusion of (6) still holds if \( l_m = l - l_i \).

Proof. Set \( F_1 = E_1 + m \) and \( F_i = E_i \) for \( 2 \leq i \leq m \). Then \( E_1 \) satisfies the hypotheses of (2) and hence is normal and nilpotent. Hence there exists a system of standard generators \( z \) of \( \mathfrak{u}(n:1) \) such that \( C_i(z) = F_i \). Now since

\[
E_1 = C_1(y),
E_2 = C_{l+1}(y) + C_{l+1}(y) + \sum_{j=1}^{n} C_j(y) \alpha_{2j},
\]

and

\[
E_i = C_{l+1}(y) + \sum_{j=1}^{n} C_j(y) \alpha_{ij} \quad \text{where the} \quad \alpha_{ij} \in \Phi,
\]

we have (by (7))

\[ F_1^{pk} = \left\{ C_{k+1}(y) + C_{m+k+1}(y) + \sum_{j=1}^{n} C_j(y) (\alpha_{m+k+1})(-1)^k \right\}(-1)^k. \]

Hence

\[
E_2 = F_1^{pk} (-1)^{l+1} + \sum_{j=1}^{n} C_j(y) (\alpha_{2j} - (\alpha_{m+k+1})(-1)^{l+1}).
\]

Now by (3.5) \( C_i(y) \) is equal to a \( \Phi \) linear combination of the \( F_1^{pk} \) for \( k \geq j - 1 \). Thus there are \( \beta_{2j} \in \Phi \) such that

\[
F_2 = E_2 = F_1^{pk} (-1)^{l+1} + \sum_{j=1}^{n-1} F_1^{pk} \beta_{2j} (\alpha_{m+k+1}) (-1)^{l+1}.
\]

Thus by (7)

\[
F_2 = C_{l+1}(y) + \sum_{j=1}^{n} C_j(z) \beta_{2j}.
\]

Similarly we see that

\[
F_1 = C_{l+1}(z) + \sum_{j=1}^{n} C_j(z) \beta_{ij} \quad \text{where the} \quad \beta_{ij} \in \Phi.
\]
for $2 < i \leq m$. Thus $(z, F) \in S$ and $t(z, F) = (l_m, \ldots, l_2, k)$ where $k > l$ so $t(z, F) > t(y, E)$.

(9) If $1 \leq u \leq v < l_u + 1$ and the $\alpha_{i_j} \in \Phi$ then

$$
\left( C_u(y) + \sum_{i=1}^{n} C_i(y) \alpha_{i_j}(y_{j_1} \cdots y_{j_k})^{p-1} \right)^p
= - \left( C_{u+1}(y) + \sum_{i=1}^{n} C_i(y) \alpha_{i_j}(y_{j_1+1} \cdots y_{j_k})^{p-1} \right).
$$

**Proof.** This follows immediately from (7) and formula (ii), p. 188 of [3].

(10) If $1 \leq u < l_u + 1$ and $u \leq v$ then

$$
\left( C_u(y) + \sum_{i=1}^{n} C_i(y) \alpha_{i_j}(y_{j_1} \cdots y_{j_k})^{p-1} \right)^p
= \left( C_{u+1}(y) + \sum_{i=1}^{n} C_i(y) \alpha_{i_j}(y_{j_1} \cdots y_{j_k})^{p-1} \right)^p
$$

**Proof.** This follows from (7) and (9).

(11) The conclusion of (6) still holds if $l_m > l - l_2$ and $l_m \geq l_m$. 

**Proof.** Set $F_i = E_i + E_m(y_{j_1} \cdots y_{j_k} + y_{j_k+1})^{p-1}$ and $F_i = E_i$ for $i > 1$. Then the result follows from (10) exactly as (8) follows from (7).

(12) Let $(y, E) \in S$ and $t(y, E) = (l_m, \ldots, l_2, l)$ where $l \neq m$. Then there exists $(z, F) \in S$ such that $F$ is equivalent to $E$ over $\mathfrak{U}(t)$ and $t(z, F) > t(y, E)$.

**Proof.** Suppose that $(y, E)$ is a counterexample. Then by (1), (6), (8), and (11) we have $l_m > l - l_2$ and $l < l_m$. Thus since $l > l_2$ we cannot have $m = 2$. Thus (12) is proved if $m = 2$.

We now proceed by induction on $m$. Assuming that (12) holds for systems of $m - 1$ derivations we see that there is a system of derivations $\{F_1, \ldots, F_{m-1}\}$ equivalent to $\{E_1, \ldots, E_{m-1}\}$ over $\mathfrak{U}(t)$ and a system of standard generators $z$ of $\mathfrak{U}(n:1)$ such that $(z, \{F_1, \ldots, F_{m-1}\})$ satisfies (3.2) for appropriate choices of the constants and that $t(y, \{E_1, \ldots, E_{m-1}\}) < t(z, \{F_1, \ldots, F_{m-1}\})$. Now $E_m$ vanishes on $\mathfrak{U}(t)$ (since $l < l_m$) so $[E_m, F_1] = 0$. Also $[z_i, F_1] \subseteq \mathfrak{U}(t)$ since each of the $E_i$ stabilizes all the $\mathfrak{U}(t)$, $F_1$ is an $\mathfrak{U}(t)$ linear combination of the $E_i$, and $\mathfrak{U}(t) \subseteq \mathfrak{U}(t)$. Thus as in (4) we see that $z_i \in \mathfrak{U}(t)$ for $1 \leq i \leq n$. Hence $z_i E_m = 0$ for $1 \leq i \leq l_m$. If we set $F_m = E_m$ and apply to $F$ the usual process for reduction to triangular form we obtain a system $G$ equivalent to $E$ over $\mathfrak{U}(t)$ and such that $(z, G) \in S$ and $t(z, G) > t(y, E)$.

(13) There exists some $(y, E) \in S$ with $t(y, E) = (l_m, \ldots, l_2, n)$.

**Proof.** If $t(y, E)$ is maximal in the lexicographic ordering of $t(S)$ then by (12) $t(y, E) = (l_m, \ldots, l_2, n)$.

As was noted above (13) is equivalent to the conclusion of Lemma 3'. Hence this completes the proof of Lemma 3 and of Theorem 1.

4. Automorphisms. In this section we will determine the automorphism group of $W(m:n)$. Throughout this section we assume that $\Phi$ is an algebraically closed
field of characteristic $p \geq 5$. We begin by stating some results of Ree which relate automorphisms of $W(m:n)$ to automorphisms of $\mathfrak{u}(m:n)$.

If $\mathfrak{u}$ is any algebra, $\sigma \in \text{Aut } \mathfrak{u}$, and $D \in \text{Der } \mathfrak{u}$ then $\sigma^{-1} D \sigma$ is again a derivation of $\mathfrak{u}$ which we will denote by $D^\sigma$. The map $\sigma : D \rightarrow D^\sigma$ is clearly an endomorphism of $\text{Der } \mathfrak{u}$. If $W$ is a subalgebra of $\text{Der } \mathfrak{u}$ an automorphism $\sigma$ of $\mathfrak{u}$ is said to be admissible to $W$ if $W \sigma \subseteq W$. The automorphisms of $\mathfrak{u}$ which are admissible to $W$ form a subsemigroup of $\text{Aut } \mathfrak{u}$ which we denote by $\text{Aut } (\mathfrak{u} : W)$. Clearly the map $\sigma \rightarrow \sigma$ is a homomorphism of $\text{Aut } (\mathfrak{u} : W)$ into $\text{End } W$. For the pairs $(\mathfrak{u}(m) : W(m))$ and $(\mathfrak{u}(m:n) : W(m:n))$ more can be said. Ree [7, p. 544] has proved

**Proposition 2.** The map $\sigma \rightarrow \sigma$ is an isomorphism of $\text{Aut } (\mathfrak{u}(m:n) : W(m:n))$ onto $\text{Aut } (W(m:n))$.

We will prove (corollary to Lemma 5) a corresponding (though weaker) result for $\mathfrak{u}(m)$.

Proposition 2 shows that to determine $\text{Aut } (W(m:n))$ it is sufficient to determine $\text{Aut } (\mathfrak{u}(m:n) : W(m:n))$. We will do this by determining

$$\text{Aut}_c (\mathfrak{u}(m) : W(m)) = \{ \sigma \in \text{Aut } (\mathfrak{u}(m) : W(m)) \mid \sigma \text{ is continuous} \}$$

and showing that $\text{Aut } (\mathfrak{u}(m:n) : W(m:n))$ is isomorphic to the stabilizer of $\mathfrak{u}(m:n)$ in $\text{Aut}_c (\mathfrak{u}(m) : W(m))$.

We now obtain (for certain subalgebras of $\mathfrak{u}(m)$) a relation between the divided power operations and the admissible automorphisms. Note that if $\mathfrak{u}$ is any subalgebra of $\mathfrak{u}(m)$ containing $1$ then $\mathfrak{u} = \Phi \oplus \mathfrak{u}_0$. Since (by (1.1)) $x^p = 0$ for all $x \in \mathfrak{u}_0$ we see that if $\sigma \in \text{Aut } \mathfrak{u}$ then $1\sigma = 1$ and $\mathfrak{u}_0 \sigma = \mathfrak{u}_0$.

**Lemma 5.** Let $\mathfrak{u}$ be a subalgebra of $\mathfrak{u}(m)$ containing $1$. Assume that

(4.1) If $y \in \mathfrak{u}_0$, $r \in \mathbb{N}$, $y^{(r)} \in \mathfrak{u}$, and $1 \leq s \leq r$ then $y^{(s)} \in \mathfrak{u}$.

(4.2) If $D \in \text{Der } \mathfrak{u}$ and if $y^{(r)} D = y^{(r-1)} (y D)$ for all $y \in \mathfrak{u}_0$ and $r \in \mathbb{N}$ such that $y^{(r)} \in \mathfrak{u}$ then $D$ has a unique extension to an element of $W(m)$.

Let $W$ be the stabilizer of $\mathfrak{u}$ in $W(m)$. (By (4.2) we may identify $W$ with a subalgebra of $\text{Der } \mathfrak{u}$.) Assume that

(4.3) If $a \in \mathfrak{u}$ and $aD = 0$ for all $D \in W$ then $a \in \Phi$.

Then for any $\sigma \in \text{Aut } \mathfrak{u}$ the following conditions are equivalent:

(4.4) If $y \in \mathfrak{u}_0$, $r \in \mathbb{N}$, and either $y^{(r)} \in \mathfrak{u}$ or $(y\sigma)^{(r)} \in \mathfrak{u}$ then $y^{(r)} \sigma = (y\sigma)^{(r)}$.

(4.5) If $y \in \mathfrak{u}_0$, $r \in \mathbb{N}$, and either $y^{(r)} \in \mathfrak{u}$ or $(y\sigma^{-1})^{(r)} \in \mathfrak{u}$ then $y^{(r)} \sigma^{-1} = (y\sigma^{-1})^{(r)}$.

(4.6) $\sigma \in \text{Aut } (\mathfrak{u} : W)$.

(4.7) $\sigma^{-1} \in \text{Aut } (\mathfrak{u} : W)$.

**Proof.** Assume that (4.4) holds, $y \in \mathfrak{u}_0$, $r \in \mathbb{N}$, and either $y^{(r)} \in \mathfrak{u}$ or $(y\sigma)^{(r)} \in \mathfrak{u}$. Then $y^{(r)} \sigma^{-1} = (y\sigma^{-1})^{(r)} \sigma^{-1} = (y\sigma^{-1})^{(r)}$. Hence (4.5) holds. Replacing $\sigma$ by $\sigma^{-1}$ we see that (4.4) and (4.5) are equivalent.

Now assume that (4.5) holds and that $D \in W$. Then if $y \in \mathfrak{u}_0$, $r \in \mathbb{N}$, and $y^{(r)} \in \mathfrak{u}$ by (4.1) we have $y^{(r-1)} \in \mathfrak{u}$ and so

$$y^{(r)} D^\sigma = y^{(r)} \sigma^{-1} D \sigma = (y\sigma^{-1})^{(r)} D \sigma = ((y\sigma^{-1})^{(r-1)} (y\sigma^{-1} D)) \sigma = y^{(r-1)} (y D)^\sigma.$$
Hence by (4.2) $D^\sigma$ has a unique extension to $W(m)$ and so $D^\sigma \in W$. Hence $\sigma \in \text{Aut } (\mathcal{A}: W)$.

Conversely assume that (4.6) holds. We will verify (4.5) by induction on $r$. Clearly $y^{(0)}\sigma^{-1} = 1 = (y\sigma^{-1})^{(0)}$ so it holds for $r = 0$. Suppose that (4.5) holds for all $r \in N$ such that $r < s$. Let $y \in \mathcal{A}$, and either $y^{(s)} \in \mathcal{A}$ or $(y\sigma^{-1})^{(s)} \in \mathcal{A}$. Then (by (4.1)) either $y^{(s-1)} \in \mathcal{A}$ or $(y\sigma^{-1})^{(s-1)} \in \mathcal{A}$ so by the induction assumption $(y\sigma^{-1})^{(s-1)} = y^{(s-1)}\sigma^{-1}$. Then for any $D \in W$,

$$y^{(s)}\sigma^{-1}D = y^{(s)}D\sigma^{-1} = (y^{(s-1)}yD^\sigma)\sigma^{-1} = (y^{(s-1)}\sigma^{-1})(yD^\sigma\sigma^{-1})$$

$$= (y\sigma^{-1})^{(s-1)}(y\sigma^{-1}D) = (y\sigma^{-1})^{(s)}D.$$

Hence $(y^{(s)}\sigma^{-1} - (y\sigma^{-1})^{(s)})D = 0$ for all $D \in W$ so by (4.3) $y^{(s)}\sigma^{-1} - (y\sigma^{-1})^{(s)} \in \Phi$. But $\sigma$ and the divided power operations stabilize $\mathcal{A}_0$ so $y^{(s)}\sigma^{-1} - (y\sigma^{-1})^{(s)} \in \Phi \cap \mathcal{A}_0 = (0)$. Hence (4.5) holds for all $r \in N$. Thus (4.5) and (4.6) are equivalent.

Replacing $\sigma$ by $\sigma^{-1}$ we see that (4.4) and (4.7) are equivalent, proving the lemma.

Note that the algebras $\mathcal{A}(m)$ and $\mathcal{A}(m:n)$ satisfy the hypotheses of the lemma. If $\mathcal{A} = \mathcal{A}(m)$ then $W = W(m)$ and if $\mathcal{A} = \mathcal{A}(m:n)$ then $W = W(m:n)$.

**Corollary.** $\text{Aut } (\mathcal{A}(m): W(m))$ is a group. The map $a \rightarrow \tilde{a}$ is an isomorphism of $\text{Aut } (\mathcal{A}(m): W(m))$ into $\text{Aut } W(m)$.

**Proof.** By the lemma $\text{Aut } (\mathcal{A}(m): W(m))$ is inverse closed and hence is a group. If $\sigma \in \text{Aut } (\mathcal{A}(m): W(m))$ then $\sigma^{-1} = (\sigma^{-1})^\sim$ and hence $\tilde{\sigma} \in \text{Aut } W(m)$. If $\tilde{\sigma}$ is the identity then for $1 \leq i, j \leq m$ we have $x_iD_j = \delta_{ij} = \delta_{ij}\sigma^{-1} = (x_iD_j)\sigma^{-1} = (x_iD_j)\sigma^{-1} = (x_i\sigma^{-1})D_j$. Thus $x_i\sigma = x_i$ for $1 \leq i \leq m$ and hence $x^{p\ell_i} = (x_i)^{(p\ell)} = (x_i\sigma)^{(p)} = (x_i)^{(p)}\sigma = x^{p\ell_i}\sigma$ for all $j \in N$. Since the $x^{p\ell_i}$ generate $\mathcal{A}(m)$, $\sigma$ is the identity. Hence $\sigma \rightarrow \tilde{\sigma}$ is an isomorphism.

Before we can determine $\text{Aut } (\mathcal{A}(m): W(m))$ we need more information about the topology of $\mathcal{A}(m)$ and the divided power operations. This is contained in the next two lemmas.

**Lemma 6.** (a) $\mathcal{A}(m) \mathcal{A}(m)_i \subseteq \mathcal{A}(m)_{i+j+1}$,

(b) $(\mathcal{A}(m))^{(0)} \subseteq \mathcal{A}(m)_{(i+1)-1}$.

**Proof.** Recalling that $\mathcal{A}(m)_i$ consists of linear combinations of $\{x^\alpha \mid |\alpha| \leq i+1\}$ we see that (a) follows from (1.1). Now if $|\alpha| \geq i+1$ then by (1.3) $x^\alpha \in \mathcal{A}(m)_{(i+1)-1}$. Assuming that (b) holds for all $j$ such that $1 \leq j < k$ and that $x_i, y \in \mathcal{A}(m)_i$ are such that $x^{(k)}$, $y^{(k)} \in \mathcal{A}(m)_{(k+1)-1}$, we see by (1.4), (1.5) and (a) that $(x + by)^{(k)} \in \mathcal{A}(m)_{(k+1)-1}$ for all $b \in \Phi$. Thus $(\mathcal{A}(m))^{(k)} \subseteq \mathcal{A}(m)_{(k+1)-1}$. Since $\mathcal{A}(m)_i$ is dense in $\mathcal{A}(m)_i$ and the divided power operations are continuous, (b) is proved.

**Lemma 7.** Let $x, y \in \mathcal{A}(m)_0$, $r, s \in N$, $r \geq 1$. Then

(4.8) $x^{(r)}y^{(s)} = C(r+s, r)x^{(r+s)}$.

(4.9) $(xy)^{(r)} = r! x^{(r)}y^{(r)}$.

(4.10) $(x^{(r)})^{(s)} = ((rs)!/(r!)^s)!x^{(rs)}$. 

**Proof.**
Proof. For \( r, s \in N \) define
\[
\mathcal{B}_{r,s} = \{ x \in \mathbb{A}(m)_0 \mid x^{(r)}x^{(s)} - C(r+s, r)x^{(r+s)} = 0 \}.
\]
Set \( \mathcal{B} = \bigcap \mathcal{B}_{r,s} \). Then (4.8) is equivalent to the statement that \( \mathcal{B} = \mathbb{A}(m)_0 \). Since each \( \mathcal{B}_{r,s} \) is the kernel of a continuous map, \( \mathcal{B} \) is closed, and hence to prove that \( \mathcal{B} = \mathbb{A}(m)_0 \), it is sufficient to prove that \( \mathcal{B} \supseteq \mathbb{A}(m)_0 \), i.e., that \( x^a \in \mathcal{B} \) for all \( 0 \neq a \in A(m) \) and that \( \mathcal{B} \) is closed under addition and scalar multiplication. Now it is easily seen from (1.3) that \( x^a \in \mathcal{B} \) for all \( 0 \neq a \in A(m) \) and from (1.4) that \( \mathcal{B} \) is closed under scalar multiplication. If \( x, y \in \mathcal{B} \) then by (1.5)
\[
(x+y)^{(r)}(x+y)^{(s)} = \left( \sum_{i=0}^r x^{(i)}y^{(r-i)} \right) \left( \sum_{j=0}^s x^{(j)}y^{(s-j)} \right)
= \sum_{i=0}^r \sum_{j=0}^s C(i+j, i)C(r+s-i-j, r-i-j)x^{(i+j)}y^{(r+s-i-j)}
= \sum_{k=0}^{r+s} A_k x^{(k)}y^{(r+s-k)}
\]
where
\[
A_k = \sum_{i=\min(r,k)}^{\max(0, k-r)} C(k, l)C(r+s-k, r-l).
\]
Now by comparing coefficients of \( (u^k/k!)(v^{r+s-k}/(r+s-k)!) \) in the identity
\[
((u+v)^r/r!)((u+v)^s/s!) = C(r+s, r)(u+v)^{r+s}/(r+s)!
\]
we see that \( A_k = C(r+s, r) \) for \( 0 \leq k \leq r+s \). Hence \( (x+y)^{(r)}(x+y)^{(s)} = C(r+s, r) \sum_{k=0}^{r+s} x^{(k)}y^{(r+s-k)} = C(r+s, r)(x+y)^{(r+s)} \) so that \( x+y \in \mathcal{B} \). This proves (4.8).

To prove (4.9) define (for \( x \in \mathbb{A}(m)_0 \))
\[
\mathcal{B}(x) = \{ y \in \mathbb{A}(m)_0 \mid (xy)^{(r)} - r! x^{(r)}y^{(r)} = 0 \text{ for all } r \in N \}
\]
and define \( \mathcal{B} = \{ x \in \mathbb{A}(m)_0 \mid \mathcal{B}(x) = \mathbb{A}(m)_0 \} \). Then \( \mathcal{B} = \bigcap \mathcal{B}(x) \) where the intersection is taken over all \( x \in \mathbb{A}(m)_0 \). Then proving (4.9) is equivalent to showing that \( \mathcal{B} = \mathbb{A}(m)_0 \). As above \( \mathcal{B}(x) \) is closed. Furthermore it is obviously closed under scalar multiplication. It is easily seen from (1.3) that for any \( 0 \neq a, \beta \in A(m) \), \( x^a \in \mathcal{B}(x^\beta) \). If \( y, z \in \mathcal{B}(x) \) then (1.5) and (4.8) show that \( y+z \in \mathcal{B}(x) \). Hence \( \mathcal{B}(x^a) \supseteq \mathbb{A}(m)_0 \) and so \( \mathcal{B}(x^a) = \mathbb{A}(m)_0 \) for all \( 0 \neq a \in A(m) \). Hence \( \mathcal{B} \supseteq \mathbb{A}(m)_0 \) and so \( \mathcal{B} = \mathbb{A}(m)_0 \) as required.

Finally to prove (4.10) we set
\[
\mathcal{B} = \{ x \in \mathbb{A}(m)_0 \mid ((x^{(r)})^{(s)} - ((rs)!/(r!)^s)s^x) = 0 \text{ for all } r, s \in N, r \geq 1 \}.
\]
As above it is sufficient to prove that \( \mathcal{B} = \mathbb{A}(m)_0 \) and since \( \mathcal{B} \) is closed it is sufficient to show that \( x^a \in \mathcal{B} \) for all \( 0 \neq a \in A(m) \) and that \( \mathcal{B} \) is closed under addition and scalar multiplication. It follows immediately from (1.3) and (1.4) that \( x^a \in \mathcal{B} \) for all \( 0 \neq a \in A(m) \) and that \( \mathcal{B} \) is closed under scalar multiplication. If \( x, y \in \mathcal{B} \) then
\[
((x+y)^{(r)}(x+y)^{(s)})^{(a)} = \left( \sum_{i=0}^r x^{(i)}y^{(r-i)} \right)^{(a)} = \sum_{i=0}^r (x^{(i)}y^{(r-i)})^{(a)}
\]
(where the summation extends over all sequences \( j_0, \ldots, j_r \) of elements of \( N \) such that \( \sum_{i=0}^r j_i = s \)). Then by (4.9) and the assumption that \( x, y \in \mathfrak{W} \) we have

\[
(x^{(d)}y^{(r-t)})^{(j_i)} = (((j_i)!)^{-1}((r-i)j_i)/(i!)^2y^{(r-t)})^{(j_i)}.
\]

Then by (4.8)

\[
\prod_{i=0}^r (x^{(d)}y^{(r-t)})^{(j_i)} = \left( t! (rs-t)! \right)^{\sum_{i=0}^r ((i!)^2(r-i)!j_i)}/x^{(d)}y^{(rs-t)}
\]

where \( t = \sum_{i=0}^r j_i \). Thus \( (x+y)^{(r)} = \sum_{i=0}^r A_t x^{(d)}y^{(rs-t)} \) where

\[
A_t = t! (rs-t)! \sum_{i=0}^r (1/(i!)^2(r-i)!j_i)!
\]

where the summation is over all sequences \( j_0, \ldots, j_r \) of elements of \( N \) such that \( \sum_{i=0}^r j_i = s \) and \( \sum_{i=0}^r i j_i = t \). Now by comparing the coefficients of \( (u/v)!/(u/v-t)! \) in the identity \( ((u+v)r)!(v-s)! = ((u+v)r)!/(rs-t)!(v-s)! \) in \( \mathbb{Z}[u,v] \) we see that \( A_t = (rs)!(r-s)!/(rs-t)! \) for \( 0 \leq t \leq rs \). Hence by (1.5) \( (x+y)^{(r)} = (x+y)(rs) \) so \( x+y \in \mathfrak{W} \). Hence \( \mathfrak{W} = \mathfrak{W}(m)_0 \).

**Lemma 8.** Let \( \sigma \in \text{Aut} \mathfrak{W}(m) \) be continuous. Then the following conditions are equivalent:

1. \( (4.11) \quad y^{(r)} \sigma = (y \sigma)^{(r)} \) for all \( y \in \mathfrak{W}(m)_0 \) and all \( r \in N \).
2. \( (4.12) \quad x^{(d)} \sigma = (x^{(d)})^\sigma \) for \( 1 \leq i \leq m \) and all \( j \in N \).

**Proof.** Clearly (4.12) is a special case of (4.11). Assume that (4.12) holds and set \( \mathfrak{W} = \{ y \in \mathfrak{W}(m)_0 \mid y^{(r)} \sigma = (y \sigma)^{(r)} \} \) for all \( r \in N \). Now \( \mathfrak{W} \) is closed under addition (by (1.5)), scalar multiplication (by (1.4)), multiplication (by (4.9)), and the divided power operations (by (4.10)). By (4.12) \( x_i \in \mathfrak{W} \) for \( 1 \leq i \leq m \). Hence \( \mathfrak{W} \supseteq \mathfrak{W}(m)_0 \). But \( \mathfrak{W} \) is closed since \( \sigma \) and the divided power operations are continuous. Hence \( \mathfrak{W} = \mathfrak{W}(m)_0 \) proving the lemma.

**Lemma 9.** Let \( \sigma \) be a continuous endomorphism of \( \mathfrak{W}(m) \). Then \( \sigma \in \text{Aut} (\mathfrak{W}(m) : W(m)) \) if and only if \( \sigma \) satisfies (4.12) and

\( (4.13) \quad \det (x_i \sigma D_j) \) is a unit in \( \mathfrak{W}(m) \).

**Proof.** Suppose that \( \sigma \) is an endomorphism of \( \mathfrak{W}(m) \) satisfying (4.11). Then for any \( \alpha \in A(m) \) by (1.1), (1.3) and Lemma 6 we have \( x^{(d)} \sigma = \prod x_i^{(d)} \sigma = \prod (x_i^\alpha)^{a(d)} \in A(m)_{|\alpha|}^{-1} \). Hence \( \mathfrak{W}(m)_i \subseteq \mathfrak{W}(m) \) for all \( i \in N \) and so \( \sigma \) induces linear maps \( \sigma_i : \mathfrak{W}(m)_{i-1} \rightarrow \mathfrak{W}(m)_{i-1} \) for all \( i \in N \).

Now suppose that \( \sigma \in \text{Aut} (\mathfrak{W}(m) : W(m)) \). Then by Lemmas 5 and 8 \( \sigma \) satisfies (4.11) and (4.12). Now since \( \sigma \) is an automorphism \( \sigma_1 \) is surjective. Since \( \mathfrak{W}(m)_0/\mathfrak{W}(m)_1 \) is finite dimensional \( \sigma_1 \) is bijective. Relative to the basis \( \{ x_i + \mathfrak{W}(m)_1 \mid 1 \leq i \leq m \} \) of \( \mathfrak{W}(m)_0/\mathfrak{W}(m)_1 \), \( \sigma_1 \) has matrix \( (x_i \sigma D_j) \psi \) where \( \psi \) is the projection of \( \mathfrak{W}(m) = \mathfrak{W}(m)_0 \oplus \Phi \) onto \( \Phi \). Since \( \sigma_1 \) is a bijection \( \psi \neq \det (x_i \sigma D_j) \psi = (\det (x_i \sigma D_j)) \psi \) so (4.13) holds.
Conversely if (4.12) and (4.13) hold and \( \sigma \) is an automorphism then by Lemmas 5 and 8 \( \sigma \in \text{Aut} (\mathcal{A}(m): W(m)) \). Hence it is sufficient to show that \( \sigma \) is an automorphism, i.e., that \( \sigma \) is bijective. We begin by showing that \( \sigma_i \) is bijective for all \( i \in \mathbb{N} \).

Since \( \det (x_i \sigma D_i) \neq 0 \), \( \sigma_i \) is bijective. Assume that \( \sigma_i \) is bijective for all \( i<i' \). Now \( \mathcal{A}(m):_{-1} \mathcal{A}(m) \) is finite dimensional so to show that \( \sigma_i \) is bijective it is sufficient to show that it is surjective. Thus it is sufficient to show that if \( \alpha \in A(m) \) and \( |\alpha|=j \) then there exists \( y \in \mathcal{A}(m):_{-1} \mathcal{A}(m) \) such that

\[(4.14)\quad y_{\alpha}=x^\alpha+z.\]

Now if \( \alpha=j \rho_k \) for some \( k \) then by (1.3) \( x^\alpha=x_j^{\rho_k} \). By the result for \( \sigma_1 \) there exist \( y_1 \in \mathcal{A}(m)_0 \) and \( z_1 \in \mathcal{A}(m)_1 \) such that \( y_1 \sigma=x_k+z_1 \). Since (4.12) and hence (by Lemma 8) (4.11) hold we have \( y_1^{\rho_k} \sigma=\sigma^\rho_k(y_1^{\rho_k})=\sigma^\rho_k(x_k+z_1) \). Now by (1.5) and Lemma 6 we have \( x_k+z_1=\sigma^{\rho_k}(x_k+z_1) \) where \( Z=\sum_{j=0}^{j-1} \sigma^{\rho_j}(x_k^{j-1}) \in \mathcal{A}(m)_j \). Thus setting \( y=y_1^{\rho_k} \) we see that (4.14) is satisfied. If \( \alpha \) is not of the form \( j \rho_k \) then we may write \( \alpha=\beta+\gamma \) where \( \beta \neq 0, \gamma \neq 0 \) and \( C(\alpha, \beta)=1 \). (For if \( \alpha(k) \neq 0 \) set \( \beta=\alpha(k) \rho_k \), and \( \gamma=\alpha-\beta \).) If \( |\beta|=i \) then \( |\gamma|=j-i \). Since \( i, j-i<j \) by the induction assumption we may find \( y_1 \in \mathcal{A}(m):_{-1} \mathcal{A}(m) \), \( z_1 \in \mathcal{A}(m)_1 \), \( y_2 \in \mathcal{A}(m):_{-1} \mathcal{A}(m) \), and \( z_2 \in \mathcal{A}(m)_1 \) such that \( y_1 \sigma=x^\beta+z_1 \) and \( y_2 \sigma=x^\beta+z_2 \). Then setting \( y=y_1 y_2 \) we see that \( y \sigma=x^\alpha+z \) where \( Z=x^\beta z_2+x^\beta z_1+z_1 z_2 \). By Lemma 4 \( y \in \mathcal{A}(m):_{-1} \mathcal{A}(m) \) and \( z \in \mathcal{A}(m)_1 \). Hence \( \sigma_j \) is bijective and so by induction \( \sigma_i \) is bijective for all \( i \).

Now suppose \( x \in \ker \sigma \). Then if \( x \in \mathcal{A}(m):_{-1} \mathcal{A}(m)_1 \) \( x+\mathcal{A}(m)_1 \) \( \in \ker \sigma \) so that \( x \in \mathcal{A}(m)_1 \). Hence \( \ker \sigma \cap \mathcal{A}(m):_{-1} \mathcal{A}(m)_1 = \{0\} \) so \( \sigma \) is injective. Finally if \( x \in \mathcal{A}(m) \) then \( x=a+x_0 \) where \( a \in \Phi \) and \( x_0 \in \mathcal{A}(m)_0 \). Since \( \sigma_1 \) is bijective there exists \( y_1 \in \mathcal{A}(m)_0 \) such that \( x_0-y_1 \sigma=x_1 \in \mathcal{A}(m)_1 \). Suppose that \( x_i \in \mathcal{A}(m)_1 \) and \( y_i \in \mathcal{A}(m):_{-1} \mathcal{A}(m)_1 \) have been defined for \( r \geq i \geq 1 \) so that \( x_{r-1}-y_i \sigma=x_r \). Then since \( \sigma_i \) is bijective there exists \( y_i \in \mathcal{A}(m):_{-1} \mathcal{A}(m)_1 \) such that \( x_{r-1}-y_i \sigma=x_r \in \mathcal{A}(m)_1 \). Thus we may inductively define \( x_i \) and \( y_i \) for all \( i \in \mathbb{N} \).

\[x=a+x_0=a+\sum_{i=1}^\infty (x_{i-1}-y_i) \sigma.\]

Then, by the continuity of \( \sigma \), \( x=y \sigma \) where \( y=a+\sum_{i=1}^\infty y_i \). Hence \( \sigma \) is bijective. This completes the proof of Lemma 9.

**Corollary 1.** If \( y_1, \ldots, y_m \in \mathcal{A}(m)_0 \) and \( \det (y_i D_i) \) is a unit then there is a unique \( \sigma \in \text{Aut} (\mathcal{A}(m): W(m)) \) satisfying \( y_i=x_i \sigma \) for \( 1 \leq i \leq m \).

**Proof.** Obviously there is a unique continuous endomorphism \( \sigma \) of \( \mathcal{A}(m) \) with \( y_i=x_i \sigma \) for \( 1 \leq i \leq m \) and satisfying (4.12). By the lemma \( \sigma \in \text{Aut} (\mathcal{A}(m): W(m)) \).

**Corollary 2.** Each \( \sigma \in \text{Aut} (\mathcal{A}(m): W(m:n)) \) can be uniquely extended to \( \tilde{\sigma} \in \text{Aut} (\mathcal{A}(m): W(m:n)) \).

**Proof.** Let \( \sigma \in \text{Aut} (\mathcal{A}(m): W(m:n)) \). In the same manner as in the lemma we see that \( \det (x_i \sigma D_i) \) is a unit in \( \mathcal{A}(m:n) \) and hence in \( \mathcal{A}(m) \). Then by Corollary 1
there is a unique $\bar{\sigma} \in \text{Aut}_c(\mathbb{A}(m) : W(m))$ such that $x_i \bar{\sigma} = x_i \sigma$ for $1 \leq i \leq m$. By Lemma 5 this implies that $\sigma$ and $\bar{\sigma}$ agree on $\mathbb{A}(m : n)$ proving the lemma.

Thus Aut $\mathbb{A}(m : n) : W(m : n)$ may be identified with the stabilizer of $\mathbb{A}(m : n)$ in Aut$_c(\mathbb{A}(m) : W(m))$. Clearly $\sigma \in \text{Aut}(\mathbb{A}(m) : W(m))$ stabilizes $\mathbb{A}(m : n)$ if and only if $(x^{p'_i})^{p'_i} \sigma \in \mathbb{A}(m : n)$ for all $1 \leq i \leq m$ and all $0 \leq j < n$. Setting $x_i \sigma = y_i$ and using (4.11) we see that this is equivalent to $y_i^{p'_i} \phi \in \mathbb{A}(m : n)$ for all $1 \leq i \leq m$ and all $0 \leq j < n$.

**Lemma 10.** If $x = \sum a(\alpha) x^\alpha$ where the summation is over all $\alpha \in A(m : n)$ and the $a(\alpha) \in \Phi$ then $x^{p'_i} \phi \in \mathbb{A}(m : n)$ for all $j$, $1 \leq j \leq k$ if and only if $a(\pi_i \phi_j) = 0$ whenever $l \geq n - k$.

**Proof.** By (1.5) we see that $x^{p'_i} \phi \in \mathbb{A}(m : n)$ for all $j$, $1 \leq j \leq k$ if and only if $(x^{p'_i})^{p'_i} \phi \in \mathbb{A}(m : n)$ for all $j$, $1 \leq j \leq k$ and all $\alpha \in A(m : n)$ such that $a(\alpha) \neq 0$. By (1.3) we see that if $j \geq 1$, $(x^{p'_i})^{p'_i} \phi = 0$ unless $\alpha = p'_i e_i$ for some $1 \leq i \leq m$ and $l \in N$, and that $(x^{p'_i})^{p'_i} \phi = x^{p'_i + l e_i}$. Thus $(x^{p'_i})^{p'_i} \phi \in \mathbb{A}(m : n)$ unless $\alpha = p'_l e_l$ where $l + j \geq n$.

Define $S(m : n)$ to be the set of all $m$-tuples $(y_1, \ldots, y_m)$ such that, for $1 \leq i \leq m$, $y_i = \sum a(i, \alpha) x^\alpha$ where the summation extends over all $0 \neq \alpha \in A(m : n)$, the $a(i, \alpha) \in \Phi$, $a(i, p'_j) = 0$ whenever $n_i + l - 1 \geq n_j$, and det $(y_j D_j)$ is a unit.

Let $V(m)$ be an $m$-dimensional vector space over $\Phi$ with basis $\{v_1, \ldots, v_m\}$ for $1 \leq i \leq m$. Define subspaces $V(m : n)$ of $V(m)$ for $1 \leq i \leq m$ by

$$V(m : n)_i = \langle v_j \mid n_j \geq \max \{n_k \mid 1 \leq k \leq m\} \rangle,$$

and

$$V(m : n)_i = \langle v_j \mid n_j \geq \max \{n_k \mid 1 \leq k \leq m, v_k \notin V(m : n)_{i-1}\} \rangle$$

for $i \geq 2$.

Let $\mathcal{V}(m : n)$ be the flag

$$V(m) = V(m : n)_m \supseteq V(m : n)_{m-1} \supseteq \cdots \supseteq V(m : n)_1 \supseteq (0).$$

Then we have the following description of Aut $(W(m : n))$ (which has been proven in the special cases $n = 1$ by Jacobson [2, §8] (where we must note that since $\Phi$ is algebraically closed $r = 0$) and $m = 1$ by Ree [7, Theorem 12.13]):

**Theorem 2.** Let $\Phi$ be an algebraically closed field of characteristic $p \geq 5$. Then Aut $(W(m : n))$ is isomorphic to Aut $(\mathbb{A}(m : n) : W(m : n))$. The map $\sigma \rightarrow (x_1 \sigma, \ldots, x_m \sigma)$ is a bijection of Aut $(\mathbb{A}(m : n) : W(m : n))$ onto $S(m : n)$ and Aut $(\mathbb{A}(m : n) : W(m : n))$ has a solvable normal subgroup $\mathcal{B}$ such that Aut $(\mathbb{A}(m : n) : W(m : n)) / \mathcal{B}$ is isomorphic to the stabilizer of $\mathcal{V}(m : n)$ in $\text{GL}(V(m))$.

**Proof.** As mentioned above Ree has proved the isomorphism of Aut $(W(m : n))$ and Aut $(\mathbb{A}(m : n) : W(m : n))$. Lemma 10 and the corollaries to Lemma 9 show that the map $\sigma \rightarrow (x_1 \sigma, \ldots, x_m \sigma)$ is a bijection of Aut $(\mathbb{A}(m : n) : W(m : n))$ onto $S(m : n)$. To prove the last statement we let $\mathcal{B}$ be the subgroup of Aut $(\mathbb{A}(m : n) : W(m : n))$ consisting of all automorphisms which induce the identity on $\mathbb{A}(m : n) / \mathbb{A}(m : n)$. Now the map $\sigma \rightarrow (a(i, e_i))_{1 \leq i, j \leq m}$ is easily seen to be a homomorphism of
Aut (\(\mathcal{A}(m:n)\): \(W(m:n)\)) onto the subgroup of GL (\(m:\Phi\)) consisting of all matrices \(a_{ij}\) such that \(a_{ij} = 0\) whenever \(n_i - n_j \geq 1\), i.e., onto the stabilizer of \(\gamma(m:n)\) in GL (\(V(m)\)). Clearly the kernel of this homomorphism is \(\mathcal{B}_1\). Thus we need only show that \(\mathcal{B}_1\) is solvable.

Let \(\sigma_i \in \mathcal{B}_1\). Then if \(x \in \mathcal{A}(m:n)_0\) we have \(x \equiv x_0 \mod \mathcal{A}(m:n)_1\). We claim that if \(x \in \mathcal{A}(m:n)_k\) then \(x \equiv x_0 \mod \mathcal{A}(m:n)_{1+k}\). To see this note that \(\mathcal{A}(m:n)_k\) is spanned by the \(x^a\) where \(|a| \geq k + 1\). Since \(x^a = \bigcap_j x_j^{(a_j)}\) Lemma 6 shows that \(x^a \equiv x_0 \mod \mathcal{A}(m:n)_{1+k}\) giving the result. Now (following [2, p. 117]) we let \(x \in \mathcal{A}(m:n)_0\), \(\sigma_i \in \mathcal{B}_1\) and \(\tau_j \in \mathcal{B}_j\). Then \(x \sigma_i^{-1} = x + x'\) where \(x' \in \mathcal{A}(m:n)_0\), \(x \tau_j^{-1} = x + x''\) where \(x'' \in \mathcal{A}(m:n)_1\), \(x' \tau_j^{-1} = x' + x'''\) where \(x''' \in \mathcal{A}(m:n)_1\), and \(x'' \sigma_i = x'' + x''''\) where \(x''''' \in \mathcal{A}(m:n)_1\). Then we have the following chain of equalities and congruences mod \(\mathcal{A}(m:n)_{1+j}\):

\[
x \sigma_i^{-1} \tau_j^{-1} \sigma_i \tau_j = (x + x') \tau_j^{-1} \sigma_i \tau_j = (x + x' + x''' + x''''') \sigma_i \tau_j \\
\equiv (x + x' + x') \sigma_i \tau_j = (x + x' + x''') \tau_j \\
\equiv (x + x') \tau_j = x.
\]

Thus \((\sigma_i, \tau_j) \in \mathcal{B}_{1+j}\). Now for \(i > \sum_{j=1}^p n_j\), \(\mathcal{A}(m:n)_i = (0)\) so \(\mathcal{B}_i = \{1\}\). Hence \(\mathcal{B}_1\) is solvable.
