WILD SPHERES IN $E^n$ THAT ARE LOCALLY FLAT MODULO TAMABLE CANTOR SETS

BY

ROBERT J. DAVERMAN(1)

ABSTRACT. Kirby has given an elementary geometric proof showing that if an $(n - 1)$-sphere $\Sigma$ in Euclidean $n$-space $E^n$ is locally flat modulo a Cantor set that is tame relative to both $\Sigma$ and $E^n$, then $\Sigma$ is locally flat. In this paper we illustrate the sharpness of the result by describing a wild $(n - 1)$-sphere $\Sigma$ in $E^n$ such that $\Sigma$ is locally flat modulo a Cantor set $C$ and $C$ is tame relative to $E^n$. These examples then are used to contrast certain properties of embedded spheres in higher dimensions with related properties of spheres in $E^3$.

Rather obviously, as Kirby points out in [11], his result cannot be weakened by dismissing the restriction that the Cantor set be tame relative to $E^n$. It is well known that a sphere in $E^n$ containing a wild (relative to $E^n$) Cantor set must be wild. Consequently the only variation on his work that merits consideration is the one mentioned above.

The phenomenon we intend to describe also occurs in 3-space. Alexander's horned sphere [1] is wild but is locally flat modulo a tame Cantor set. In fact, at one spot methods used here parallel those used to construct that example. However, other properties of 3-space are strikingly dissimilar to what can be derived from the higher dimensional examples constructed here, for, as discussed in §2, natural analogues to some important results concerning locally flat embeddings in $E^3$ are false.

Most of the terminology and notation is standard. We distinguish between the two senses of the term "boundary" by using $\partial M$ to denote the boundary of a manifold $M$ and $\text{Bd} A$, for $A \subset X$, to denote the boundary of $A$ in the space $X$. Our standard $k$-cell $B^k$ is the set of points in $E^n$ of norm $\leq 1$. We use $\rho$ to denote the standard complete metric on $E^n$, and for two maps $f$ and $f'$ of a space $X$ into $E^{n+1}$, we use $\rho(f, f')$ to denote $\text{lub} \{\rho(f(x), f'(x))|x \in X\}$.

1. Construction of certain wild spheres. The somewhat intricate definition and lemma that follow are designed to slip naturally into the proof of Theorem 3.
and could readily have been incorporated there. By isolating the formation of special Cantor sets, however, we profit in two ways, the most obvious being a precise specification of those Cantor sets in the embedded sphere that can be employed; the other, a convenient description of locally flat embeddings that converge to the wild embedding desired in Theorem 3.

Let $Q$ denote an $n$-manifold, $n > 3$, and $C$ a Cantor set embedded in $Q$. A sequence $\{M_i\}_{i=1}^{\infty}$ of compact $n$-manifolds with boundary in $Q$ is a defining sequence for $C$ iff (1) $C = \bigcap M_i$, and (2) $M_{i+1} \subset \text{Int } M_i$ for each $i$. The sequence $\{M_i\}$ is called a doubly regular defining sequence for $C$ if, in addition, the following conditions are satisfied: (3) each component of each $M_i$ is homeomorphic to $B^2 \times T^{n-2}$, where $T^{n-2}$ denotes the Cartesian product of $n-2$ copies of $S^1$; (4) the inclusion of each boundary component of $Y_i = M_i - \text{Int } M_{i+1}$ into the appropriate component of $Y_i$ induces an injection of fundamental groups; (5) for every odd positive integer $i$ and every component $P$ of $M_i$, $P \cap M_{i+1}$ consists of exactly two components $C_1$ and $C_2$ determined by disjoint subdisks $B_1$ and $B_2$ of $\text{Int } B^2$ such that, under some homeomorphism $h$ of $B^2 \times T^{n-2}$ onto $P$, $C_e = h(B_e \times T^{n-2})$ ($e = 1, 2$), and, furthermore, there exists a homeomorphism $g$ of $B_1$ onto $B_2$ reversing the induced orientations on these two disks such that

$$h(g \times 1_T \times 1_{T^{n-2}}) h^{-1} (C_1 \cap M_k) = C_2 \cap M_k \quad \text{for all } k > i.$$

Remark. It would be permissible in condition (3) above to require instead that to each component $P$ of $M_i$ there correspond an $(n-2)$-manifold $N_P$ such that $P$ and $B^2 \times N_P$ are homeomorphic; but we have found it more convenient to specify $N_P$ as $T^{n-2}$.

Lemma 1. For $n > 3$ there exists a Cantor set $C$ in $S^n$ that has a doubly regular defining sequence.

Proof. Consider a sequence $\{N_i\}_{i=1}^{\infty}$ of compact $n$-manifolds with boundary in $S^n$ such that (1) $\bigcap N_i$ is a Cantor set, (2) $N_{i+1} \subset \text{Int } N_i$, (3) each component of $N_i$ is homeomorphic to $B^2 \times T^{n-2}$, and (4) the inclusion of each boundary component of $Z_i = N_i - \text{Int } N_{i+1}$ into the appropriate component of $Z_i$ induces an injection of fundamental groups. We shall assume the reader is acquainted with Cantor sets in $S^n$ having such defining sequences, for example, Antoine's necklace in $S^3$ [2] and Blankenship's generalizations in higher dimensional spheres [4].

(Explicit comments regarding why condition (4) applies in these cases can be found in [14].) We shall modify the sequence $\{N_i\}$ to obtain a doubly regular defining sequence for another Cantor set, which might be embedded differently than $\bigcap N_i$.

Let $M_1 = N_1$. Fix two disjoint disks $B_1$ and $B_2$ in $\text{Int } B^2$. Then for each
component $R$ of $M_1$ there exists a homeomorphism $h_R$ of $B^2 \times T^{n-2}$ onto $R$. Define $M_2$ as the union of the sets $h_R((B_1 \cup B_2) \times T^{n-2})$.

For $M_3$ we mimic a portion of $\{N_i\}$ in each component of $M_2$, attending to epsilomics to force $\bigcap M_i$ to be a Cantor set while exercising technical care in light of condition (5). Fix homeomorphisms $g_e$ of $B^2$ onto $B_e$ ($e = 1, 2$) such that $g_2g_1^{-1}: B_1 \to B_2$ reverses the orientations induced from $B^2$, and define $G_e = g_e \times 1_{T^{n-2}}: B^2 \times T^{n-2} \to B_e \times T^{n-2}$. For each component $R$ of $M_1$ we have homeomorphisms $h_RG_eh_R^{-1}$ of $R$ onto components of $M_2$; thus, there exists an integer $j(R) > 1$ such that for each component $X$ of $R \cap N_{j(R)}$

$$\text{diam } h_RG_eh_R^{-1}(X) < 1/3 \quad (e = 1, 2).$$

We define $M_3$ to be the union of the sets $h_RG_eh_R^{-1}(R \cap N_{j(R)})$. Note that the components $C_e = h_R(B_e \times T^{n-2})$ of $M_2$ satisfy

$$h_RG_2G_1^{-1}h_R^{-1}(C_1 \cap M_3) = C_2 \cap M_3.$$

Now $M_4$ is defined by choosing, for each component $R'$ of $M_3$, two disjoint parallel copies of $R'$ in its interior. Specifically, for each component $R_1$ of $M_1$ and each component $R_3$ of $R_1 \cap N_{j(R_1)}$, there exists a homeomorphism $h_{R_3}$ of $B^2 \times T^{n-2}$ onto $R_3$. Define $M_4$ as the union of all such sets

$$h_{R_1}G_eh_{R_1}^{-1}h_{R_3}((B_1 \cup B_2) \times T^{n-2}) \quad (e = 1, 2).$$

Note again that the components $C_e = h_{R_1}(B_e \times T^{n-2})$ of $M_2$ satisfy

$$h_{R_1}G_2G_1^{-1}h_{R_1}^{-1}(C_1 \cap M_4) = C_2 \cap M_4.$$

Given a component $R_1$ of $N_1 = M_1$ and a component $R_3$ of $R_1 \cap N_{j(R_1)}$, we have homeomorphisms $h_{R_1}G_{e_1}h_{R_1}^{-1}h_{R_3}G_{e_3}h_{R_3}^{-1}$ ($e_1 = 1, 2; e_3 = 1, 2$) of $R_3$ onto components of $M_4$. Thus, there exists an integer $j(R_3) > j(R_1)$ such that for each component $X$ of $R_3 \cap N_{j(R_3)}$

$$\text{diam } h_{R_1}G_{e_1}h_{R_1}^{-1}h_{R_3}G_{e_3}h_{R_3}^{-1}(X) < 1/5 \quad (e_1 = 1, 2; e_3 = 1, 2),$$

and we define $M_5$ to be the union of such sets, emphasizing that this be done for each possible $R_1$ and $R_3$.

We continue this process, making certain that each component of $M_{2i+1}$ has diameter less than $1/(2i + 1)$. Implicit in our procedure is the requirement that for each component $R$ of $M_p$, $R \cap M_{j+1} \neq \emptyset$, which implies that $\bigcap M_i$ is a Cantor set. Furthermore, for each odd integer $i > 0$, a set $P$ is a component of $M_i$ if (1) there exist sets $R_1, R_3, \cdots, R_i$ such that $R_1$ is a component of $N_1$
and $R_{k+2}$ is a component of $R_k \cap N_{j(R_k)}$ ($k = 1, 3, \ldots, i - 2$) and (2) there exist homeomorphisms $h_{R_k}$ of $B^2 \times T^{n-2}$ onto $R_k$ ($k = 1, 3, \ldots, i - 2$) such that $P = H_1 H_2 \cdots H_{i-2}(R_j)$, where $H_k = h_{R_k} \cdot G_{e_k} \cdot h_{R_k}^{-1}$ ($e_k = 1, 2$). In case $i$ is odd each component of $M_i$ contains exactly two components of $M_{i+1}$, which are obtained by a rule analogous to that given in defining $M_2$ and $M_4$. It follows that the resulting sequence $\{M_i\}$ is a doubly regular defining sequence for $\bigcap M_i$; condition (5) is verifiable in straightforward fashion in terms of the specific homeomorphisms concocted to determine components of the $M_i$'s; condition (4) is obvious in case $i$ is odd, and in case $i$ is even it is a consequence of properties of $\{N_j\}$, since to each component $Y_i$ of $M_i - \operatorname{Int} M_{i+1}$ there correspond integers $j$ and $k$ such that $Y_i$ is homeomorphic to a component of $N_j - \operatorname{Int} N_k$.

The following lemma, which is used in proving Corollary 9, is not essential for the main results of the paper.

**Lemma 2.** For $n \geq 3$ there exists a Cantor set $C^*$ in $S^n$ such that $C^*$ has a doubly regular defining sequence and $S^n - C^*$ is simply connected.

**Proof.** DeGryse and Osborne [9] have discovered a wild Cantor set $A$ in $S^n$ ($n \geq 3$) having simply connected complement and having a defining sequence $\{N_j\}$ that satisfies conditions (3) and (4) in the definition of "doubly regular defining sequence." Relying largely on their techniques we shall suggest briefly how to establish that a Cantor set $C^*$ constructed from $\{N_j\}$ according to the rules formulated in Lemma 1 also has simply connected complement. In [9] a defining sequence $\{A^*_i\}$ is prescribed for $A$, and we have set $N_1 = A^*_0$ and $N_j = A^*_j - 3$ ($j \geq 2$) because this affords easy application of [9, Theorem 4.13]. Furthermore, following [9], throughout this proof $T^n_i$ denotes an $n$-tube, which is a space homeomorphic to $B^2 \times T^{n-2}$. The algebraic manipulations of [9] focus on the following definition.

Let $\{T^n_i, i = 1, 2, \ldots, k\}$ be a collection of pairwise disjoint $n$-tubes in $\operatorname{Int} T^n_0$. Let $P$ be a tree in $T^n_0 - \bigcup_{i=1}^k \operatorname{Int} T^n_i$ such that $P \cap \partial T^n_i$ is a single point for $i = 0, 1, \ldots, k$. Let $K_i = \ker(\pi_1(\partial T^n_i) \to \pi_1(T^n_i))$ and let $G_i$ be a subgroup of $\pi_1(\partial T^n_i)$ such that $K_i \oplus G_i = \pi_1(\partial T^n_i)$. Denote by $H_0$ the smallest normal subgroup of $\pi_1(T^n_0 - \bigcup_{i=1}^k \operatorname{Int} T^n_i)$ containing $\text{im}(G_0 \to \pi_1(T^n_0 - \bigcup_{i=1}^k \operatorname{Int} T^n_i))$. The $n$-tubes $\{T^n_i, i = 1, 2, \ldots, k\}$ are $h$-unlinkable in $T^n_0$ if for every $i = 1, 2, \ldots, k$

$$G_i \subseteq \ker\left[\pi_1(\partial T^n_i) \to \pi_1\left(T^n_0 - \bigcup_{i=1}^k \operatorname{Int} T^n_i\right)/H_0\right]$$

and
is an epimorphism.

Using the notation $T^n_0 = B^2 \times T^{n-2}$ and $T^n_e = B^2_e \times T^{n-2}$ ($e = 1, 2$), we claim that $\{T^n_1, T^n_2\}$ are $h$-unlinkable in $T^n_0$. To prove it we can define an appropriate tree $P$ in $B^2 \times t$ ($t \in T^{n-2}$) as the union of two arcs $\alpha_e \times t$, each joining a point of $\partial T^n_0$ to a point of $\partial T^n_e$. Note that $G_0$ is generated by loops in $p_0 \times T^{n-2}$, where $p_0 \in \partial B^2$, and that $G_e$ similarly is generated by loops in $p_e \times T^{n-2}$, where $p_e \in \partial B^e$. It follows, by deforming loops in $p_e \times T^{n-2}$ across $\alpha_e \times T^{n-2}$ into $p_0 \times T^{n-2}$, that each loop representing an element of $G_e$ is homotopic in $T^n_0 - \text{Int}(T^n_1 \cup T^n_2)$ to a loop representing an element of $G_0$. Furthermore, we see that

$$\pi_1(T^n_0 - \text{Int}(T^n_1 \cup T^n_2)) \cong \pi_1(B^2 - \text{Int}(B_1 \cup B_2)) \times \pi_1(T^{n-2})$$

and $H_0$ corresponds to the $\pi_1(T^{n-2})$ factor. Since $B^2 - \text{Int}(B_1 \cup B_2)$ collapses to $(\alpha_1 \cup \alpha_2) \cup (\partial B_1 \cup \partial B_2)$, it follows that

$$\pi_1(P \cup (\partial T^n_1 \cup \partial T^n_2)) \rightarrow \pi_1(T^n_0 - \text{Int}(T^n_1 \cup T^n_2))/H_0$$

is an epimorphism. This establishes the claim.

We can assume that $A^n_0 = N_1$ consists of a single component such that

$$G_0 \subset \ker(\pi_1(\partial A^n_0) \rightarrow \pi_1(S^n - \text{Int} A^n_0))$$

and that $\{M_i\}$ is the doubly regular defining sequence determined from $\{N_i\}$ by applying Lemma 1. It follows from the claim and repeated applications of [9, Lemma 4.9] that the components of each $M_i$ are $h$-unlinkable in the $n$-tube $A^n_0$. Theorem 4.13 of [9] then implies that the inclusion induced homomorphism

$$\pi_1(S^n - M_k) \rightarrow \pi_1(S^n - M_{k+1})$$

is trivial for even indices $k$. This proves that $S^n - C^* = S^n - \bigcap M_i$ is simply connected.

**Theorem 3.** If the Cantor set $C$ in $S^n$ ($n \geq 3$) has a doubly regular defining sequence $\{M_i\}$, then there exists a wild embedding $f: S^n \rightarrow E^{n+1}$ such that $f$ is locally flat at each point of $S^n - C$ and $f(C)$ is tame relative to $E^{n+1}$.

**Proof.** Construction of $f$. We shall obtain $f$ as the limit of a sequence of embeddings of $S^n$ in $E^{n+1}$. Throughout the proof all embeddings, excepting $f$, of manifolds and of manifolds with boundary will be locally flat.

Let $f_1$ denote an embedding of $S^n$ onto the boundary of a round $(n + 1)$-ball $D$ in $E^{n+1}$. Appealing to the definition of "doubly regular defining sequence,"

$$\pi_1(P \cup k \partial T^n_i) \rightarrow \pi_1(T^n_0 - \bigcup \text{Int} T^n_i)/H_0$$
we can easily obtain an embedding \( g_1 : I \times M_1 \to E^{n+1} \) such that

\[
(6) \quad g_1(I \times M_1) \cap D = g_1(\partial I \times M_1) = f_1(M_2).
\]

To do this, for each component \( R \) of \( M_1 \), we use the collar structure on \( S \) in \( E^{n+1} - \text{Int} \ D \) to “extend” \( f_1 h_R : B^2 \times T^{n-2} \to f_1(R) \) to an embedding \( F_R \) of \( I \times B^2 \times T^{n-2} \) into \( E^{n+1} - \text{Int} \ D \) such that

\[
F_R(I \times B^2 \times T^{n-2}) \cap S = F_R([0] \times B^2 \times T^{n-2}) = f_1(R)
\]

where \( F_R((0, b, t)) = f_1 h_R((b, t)) \) for \( (b, t) \in B^2 \times T^{n-2} \). We require, in addition, that the images of the various \( F_R \) be pairwise disjoint. The orientation reversing homeomorphism \( g : B_1 \to B_2 \) (the subdisks of \( \text{Int} B^2 \)) prescribed in the definition of “doubly regular” can be realized in terms of a locally flat embedding \( \psi \) of \( I \times B^2 \) in \( I \times B^2 \) such that

\[
\psi(I \times B^2) \cap \partial(I \times B^2) = \psi(\partial I \times B^2),
\]

\[
\psi([0] \times B^2) = [0] \times B_1,
\]

\[
\psi([1] \times B^2) = [0] \times B_2,
\]

where \( \psi \) is related to \( g \) in the following sense: for each \( b \in B^2 \), \( \psi((0, b)) = (0, b_1) \) and \( \psi((1, b)) = (0, g(b_1)) \). Define \( g_1 : I \times M_1 \to E^{n+1} \) on each component \( R \) of \( M_1 \) as \( g_1 = F_R(\psi \times 1_{T^{n-2}})(1_I \times h_R^{-1}) \). Now condition (5) in the pertinent definition permits us to assert that there is a subset \( L_1 \) of \( M_2 \), namely that “half” of \( M_2 \) corresponding to the images of \( B_1 \times T^{n-2} \) under certain homeomorphisms of \( B^2 \times T^{n-2} \) onto components of \( M_1 \), such that for \( k > 2 \),

\[
(7) \quad g_1(\partial I \times (L_1 \cap M_k)) = f_1(M_k).
\]

Let \( A_1 = g_1(I \times M_1) \). Without loss of generality we may assume

\[
(8) \quad \text{diam } A_1 < 1.
\]

There exists an odd positive integer \( j(2) \) such that for each component \( X_{2,e} \) (\( e = 1, \cdots , n_2 \)) of \( M_{j(2)} \)

\[
(9) \quad \text{diam } g_1(t \times X_{2,e}) < \frac{1}{2} \text{ for each } t \in I.
\]

There exists a homeomorphism \( H_{2,e} \) of \( I \times B^2 \times T^{n-2} \) onto \( g_1(I \times X_{2,e}) \) such that

\[
(10) \quad H_{2,e}(t \times B^2 \times T^{n-2}) = g_1(t \times X_{2,e}) \text{ for each } t \in I.
\]

Represent \( I \times B^2 \) as a solid cylinder as shown in the figure, and let \( R_1 \) and \( R_2 \) denote the cubes-with-one-handle as indicated. Note that the handles in \( R_e \) can be made arbitrarily thin, and consequently the solid cylinder \( R^*_\delta \) can be constructed with arbitrarily small preassigned diameter \( (\delta = 1, 2) \). In particular, using (9) and (10) we require that

\[
(11) \quad \text{diam } H_{2,e}(R^*_\delta \times T^{n-2}) < \frac{1}{2} \quad (\delta = 1, 2; e = 1, \cdots , n_2).
\]
Define

\[ A_2 = \bigcup_{e=1}^{n_2} H_{2,e}((R_1^* \cup R_2^*) \times T^{n-2}), \]

\[ Q = [(\text{Int } I \times B^2)] \cap [\partial \text{ Cl}(R_1 - R_1^*) \cup \partial \text{ Cl}(R_2 - R_2^*)], \]

\[ Q^* = [R_1^* \cap \text{ Cl}(R_1 - R_1^*)] \cup [R_2^* \cap \text{ Cl}(R_2 - R_2^*)]. \]

Here \( Q \) is the union of the interiors of two disks while \( Q^* \) is the union of four disks. We see that there exists a homeomorphism \( f_2 \) of \( S^n \) onto

\[ f_1(S^n - \text{Int } M_{j(2)}) \cup \left( \bigcup_{e=1}^{n_2} H_{2,e}(Q \times T^{n-2}) \right) \]

such that

1. \( f_2|S^n - \text{Int } M_{j(2)} = f_1|S^n - \text{Int } M_{j(2)} \),
2. \( f_2(M_{j(2)+1}) = \bigcup_{e=1}^{n_2} H_{2,e}(Q^* \times T^{n-2}). \)

It follows from (8) that \( \rho(f_2, f_1) < 1. \)
To continue, note that by (13) and by the definitions of $A_2$, $Q^*$ and the $R^*_\delta$'s we can define a homeomorphism $g_2$ of $I \times M_{j(2)}$ onto $A_2$ such that
\[ f_2(M_{j(2)} \cup I) = g_2(I \times M_{j(2)}). \]
Specifically, using condition (5) in the definition of “doubly regular defining sequence” we find a subset $L_{j(2)}$ of $M_{j(2)}$, the union of half of the components of $M_{j(2)}$, chosen as before, such that for $k > j(2) + 1$
\[ g_2(\partial I \times (L_{j(2)} \cap M_k)) = f_2(M_k). \]
There exists an odd integer $j(3) > j(2)$ such that for each component $X_{3,e}$ ($e = 1, \ldots, n_3$) of $M_{j(3)}$
\[ \operatorname{diam} g_3(t \times X_{3,e}) < 1/3 \text{ for each } t \in I. \]
There also exists a homeomorphism $H_{3,e}$ of $I \times B^2 \times T^{n-2}$ onto $g_2(I \times X_{3,e})$ such that
\[ H_{3,e}(t \times B^2 \times T^{n-2}) = g_2(t \times X_{3,e}) \text{ for each } t \in I. \]
In particular, we can suppose now that $R^*_1$ and $R^*_2$ are so constructed that
\[ \operatorname{diam} H_{3,e}(R^*_\delta \times T^{n-2}) < 1/3 \text{ for } \delta = 1, 2; e = 1, \ldots, n_3. \]
It follows that there exists a homeomorphism $f_3$ of $S^n$ onto
\[ f_2(S^n - \text{Int } M_{j(3)}) \cup \bigcup_{e=1}^{n_3} H_{3,e}(Q \times T^{n-2}) \]
such that
\[ f_3|S^n - \text{Int } M_{j(3)} = f_2|S^n - \text{Int } M_{j(3)} \]
\[ f_3(M_{j(3)} \cup I) = \bigcup_{e=1}^{n_3} H_{3,e}(Q \times T^{n-2}). \]
It follows from (11) that $\rho(f_3, f_2) < \frac{1}{2}$.

By repeating this process we can establish the existence of an increasing sequence $\{j(i)\}_{i=2}^{\infty}$ of odd positive integers, a sequence $\{f_i\}_{i=1}^{\infty}$ of locally flat imbeddings of $S^n$ into $E^{n+1}$, and a decreasing sequence $\{A_i\}_{i=1}^{\infty}$ of compact subsets of $E^{n+1}$ such that, for $i = 1, 2, \ldots$,
\[ \rho(f_{i+1}, f_i) < 1/i, \]
\[ f_{i+1}|S^n - \text{Int } M_{j(i+1)} = f_i|S^n - \text{Int } M_{j(i+1)}, \]
\[ f_{i+1}(M_{j(i+1)}) \subset A_{i+1}, \]
\[ \operatorname{diam} \text{(largest component of } A_i \text{)} \to 0 \text{ as } i \to \infty, \]
\[ \text{if } x \text{ and } y \text{ belong to distinct components of } M_{j(i+1)}, \text{ then } f_{i+1}(x) \text{ and } f_{i+1}(y) \text{ belong to distinct components of } A_{i+1}, \]
\[ A_{i+1} \text{ is homeomorphic to } I \times M_{j(i+1)}. \]
One can show in routine fashion that $f = \lim f_i$ is an embedding, and (22) implies that $f$ is locally flat at each point of $S^n - C$.

**Proof that $f(C)$ is tame.** By (23) $f(C) \subset \bigcap A_i$. It follows from (26) that $f(C)$ has a defining sequence in $E^{n+1}$ such that each component at each stage
has an \((n - 2)\)-spine. Because these spines have codimension 3 relative to \(E^{n+1}\), \(f(C)\) is defined by cells and must be tame (see the proof of [16, Corollary 1]).

**Proof that \(f\) is a wild embedding.** Let \(h(B^2 \times T^{n-2})\) denote one of the components of \(M_2\), and let \(U\) denote the bounded component of \(E^{n+1} - f(S^n)\). Define a homeomorphism \(m\) of \(B^2\) onto \(fh(B^2 \times p) \subset A_1\), for some \(p \in T^{n-2}\). If \(f\) were locally flat at each point, locally \(m(B^2)\) could be pushed slightly into \(E^{n+1} - \text{Cl} \ U\). Consequently we shall have proved that \(f\) is wild once we establish the following: \(m' \colon B^2 \to A_1\) is a map such that \(m'|\partial B^2 = m|\partial B^2\), then \(m'(\text{Int} B^2) \cap f(S^n) \neq \emptyset\). An equivalent statement, based on the construction of \(f\), is the following: \(m' \colon B^2 \to A_1\) is a map such that \(m'|\partial B^2 = m|\partial B^2\) and if \(k \geq 2\) is an integer, then \(m'(\text{Int} B^2) \cap (f_k(S^n) \cup A_k) \neq \emptyset\).

To prove the latter of these two statements, we decompose a set slightly larger than the “best” component of \(A_1 - (f_k(S^n) \cup A_k)\). For \(i = 1, \cdots, k - 1\) define \(U_{i+1}\) as the bounded component of \(E^{n+1} - f_{i+1}(S^n)\) and

\[
Z_i = A_i - (A_{i+1} \cup U_{i+1} \cup (f_{i+1}(S^n) \cap \text{Int} A_i)).
\]

Retracing our earlier constructions, we find that

\[
Z_i = g_i(I \times [M_{j(i)} - (L_{j(i)} \cap \text{Int} M_{j(i+1)} + 1)]) \\
\cup \left( \bigcup_{e=1}^{n_{i+1}} H_{i+1, e} \left( [(\text{Int} I \times B^2) - (R_1 \cup R_2)] \times T^{n-2} \right) \right),
\]

where we have set \(j(1) = 1\). Recall that \(M_{j(i)} - \text{Int} L_{j(i)}\) is homeomorphic to \(I \times \partial M_{j(i)}\) because \(L_{j(i)}\) was defined so as to contain exactly one component of \(M_{j(i)+1}\) in each component of \(M_{j(i)}\) and because condition (5) in the definition of “doubly regular defining sequence” implies that \(L_{j(i)}\) is situated nicely in \(M_{j(i)}\). Consequently \(M_{j(i)} - (L_{j(i)} \cap \text{Int} M_{j(i+1)})\) is homeomorphic to \(L_{j(i)} - \text{Int} M_{j(i+1)}\). It follows from several applications of condition (4) in the definition of “doubly regular ...” that the inclusion of each \(H_{i+1, e}(\text{Int} I \times \partial B^2 \times T^{n-2})\) into its intersection with

\[
g_i(I \times [M_{j(i)} - (L_{j(i)} \cap \text{Int} M_{j(i+1)} + 1)])
\]

induces an injection of fundamental groups. It follows from Theorem 9 of [3] that the inclusion of each \(H_{i+1, e}(\text{Int} I \times \partial B^2 \times T^{n-2})\) into

\[
H_{i+1, e}( [(\text{Int} I \times B^2) - (R_1 \cup R_2)] \times T^{n-2})
\]

also induces a fundamental group injection. For similar reasons the inclusions of each component \(S\) of \(Z_{i+1} \cap \text{Cl} \ Z_i\) into \(Z_{i+1}\) and \(S \cup Z_i\), respectively (\(S\) is
homeomorphic to $\text{Int } I \times S^1 \times T^{n-2}$ and corresponds to the product of $\text{Int } I$ with the boundary of a component of $M_j(i+1)$ or to the image under some $H_{i,e}$ of the product of an open annulus in $\partial R^*_e$ with $T^{n-2}$, induce injections. In short, $\pi_1(\bigcup Z_i)$ is a generalized free product with amalgamation. According to the definition of $m$, $m(\partial B^2) = f_\lambda(\partial B^2 \times \lambda) \subset \partial A_1$, which means that $m(\partial B^2)$ is not contractible in $f_\lambda(\partial B^2 \times T^{n-2})$ nor in $g_1(I \times \partial M_1)$. From the above remarks we find first that $m|\partial B^2$ is not null homotopic in

$$g_1(I \times [M_1 - (L_1 \cap \text{Int } M_{j(2)})])$$

and second that $m|\partial B^2$ is not null homotopic in $\bigcup Z_i$. Since the unique component of $A_1 - (f_k(S^n) \cup A_k)$ whose closure contains $m(\partial B^2)$ is a subset of $\bigcup Z_i$, the statement at the end of the preceding paragraph holds, and the proof is complete.

Addendum. The closure $B$ of the bounded component of $E^{n+1} - f(S^n)$ is an $(n + 1)$-cell. This can be established in elementary fashion by carefully extending the locally flat embeddings $f_i$ to embeddings $F_i$ of $B^{n+1}$ in such a way that the $F_i$'s obviously converge to an embedding. Alternatively, for $n + 1 \geq 5$ this follows from Theorem 6 of [15], because $f$ can be approximated arbitrarily closely by locally flat embeddings in $(B - f(S^n))$.

**Corollary 4.** There exists a wild $n$-cell $B$ in $E^n$ ($n \geq 4$) such that $\partial B$ is locally flat modulo a Cantor set that is tame relative to $E^n$.

2. Generalizations of certain 3-space theorems in higher dimensions. The embeddings described in §1 signify that in dimensions greater than three $(n - 1)$-spheres and $n$-cells in $E^n$ can have properties contradictory to results concerning the comparable properties in 3-space. This section is devoted to contrasting some prominent 3-dimensional tameness theorems with higher dimensional versions.

**Corollary 5.** For $1 < k < n$ and $n \geq 4$ there exists a wild $(n - 1)$-sphere $\Sigma$ in $E^n$ that is locally flat modulo a flat (relative to $E^n$) $k$-cell.

**Proof.** Let $f : S^{n-1} \to E^n$ be a wild embedding promised by Theorem 3 such that, for some Cantor set $C$ in $S^{n-1}$, $f$ is locally flat modulo $C$ and $f(C)$ is tame. In $S^{n-1}$ there exists an $(n - 1)$-cell $B$ such that $\partial B$ contains $C$, $\partial B$ is locally flat in $S^{n-1}$ modulo $C$, and $C$ is a tame subset of $\partial B$ (the technique for forming $B$ is due to Alexander [1], was generalized by Blankenship [4, Theorem 3F], and has been formalized by Osborne [13, Theorem 3]). Obviously $f(S^{n-1})$ is locally flat modulo $f(B)$, and it follows from [11] that $f(B)$ is flat relative to $E^n$. Now for $1 < k < n - 1$ it is a simple matter to identify a $k$-cell $K$ in $f(B)$ that is flat relative to $E^n$ and that contains $f(C)$, completing the proof.
Compare Corollary 5 with Theorem 2 of [10].

Corollary 6. There exist two n-cells $D$ and $D'$ in $E^n$ ($n \geq 4$) such that
$\partial D$ is wildly embedded at each point of a Cantor set $C$, $\partial D'$ is locally flat at each
point, and $C \subset D' \subset D$.

Proof. Using the proof and terminology of Corollary 5, we let $D$ denote
the closure of the bounded component of $f(S^{n-1})$, and we thicken the (flat)
$(n-1)$-cell $f(B)$ to form a flat $n$-cell $D'$ in $D$.

Corollary 6, which should be compared with Theorem 5 of [5], reveals that
the theory of *-taming sets developed in [8] does not expand to rich generalizations in high dimensions, because, as Cannon points out in [8], Burgess' work in [5] can be regarded as an initial result about *-taming sets. Should one attempt
to extend the definition of *-taming set (see [8]) without additional restrictions,
Corollary 7 indicates how limited a theory would result.

A crumpled n-cube is a space homeomorphic to the closure of a component
of $S^n - \Sigma$, where $\Sigma$ denotes an $(n-1)$-sphere topologically embedded in $S^n$.

Corollary 7. Suppose $X$ is a compact proper subset of $S^n$ ($n \geq 4$)
having the following property: if $K$ is a crumpled n-cube in $S^n$ such that $K \cap
X \subset \text{Bd} \ K$ and $\text{Bd} \ K$ is locally flat at each point of $\text{Bd} \ K - X$, then $K$ is an n-cell.
Then $X$ is a countable set.

Proof. Suppose to the contrary that $X$ is uncountable. Starting with a
flat n-cell $B$ in $S^n - X$, we can pull out arms from $B$ towards $X$, as was done in
Theorem 3 of [13], to obtain an embedding $g$ of $B$ into $S^n$ such that $g^{-1}(g(B) \cap X)$
is a Cantor set $C'$ that is tame relative to $\partial B$ and $g|\partial B$ is locally flat modulo $C'$.

Using the notation of Corollary 6, we then can define an embedding $f$ of $E^n - \text{Int} \ D'$ into $g(B)$ such that $f(\partial D') = g(\partial B)$ and $f(C) = g(C')$. Define $K$ to be the
closure of the component of $S^n - f(\partial D)$ contained in $B$. Since $K$ satisfies the
property in the hypothesis, it must be an n-cell. This leads to a contradiction,
however, because $K - \{p\}$ (for $p \in K - f(\partial D)$) is homeomorphic to $E^n - \text{Int} \ D$.

A similar argument may be given for one implication in the following corol-
lary, which provides a characterization of taming sets for $(n-1)$-spheres in $E^n$
($n \geq 4$) that should be compared with the more positive results collected in [7].
The other implication can be derived from [11].

Corollary 8. Let $X$ be a compact, proper subset of an $(n-1)$-sphere in
$E^n$ ($n \geq 4$). Then $X$ is countable if and only if, for each $(n-1)$-sphere $\Sigma$ in $E^n$
that contains $X$ and that is locally flat modulo $X$, $\Sigma$ is locally flat.
**Corollary 9.** There exists a wild $n$-cell $B$ in $E^n$ ($n \geq 5$) such that $B$ is cellular and the set of points at which $\partial B$ is wildly embedded is a Cantor set.

**Proof.** By Lemma 2 and Theorem 3 there exists an $n$-cell $B$ in $E^n$ such that (i) $\partial B$ is wildly embedded, (ii) $\partial B$ is locally flat modulo a Cantor set $C$, (iii) $\partial B - C$ is simply connected, and (iv) $C$ is tame relative to $E^n$. To show that $B$ is cellular we sketch a proof that $B$ satisfies McMillan's cellularity criterion [12, Theorem 1]. Given a neighborhood $U$ of $B$ we choose a neighborhood $V$ of $B$ such that any loop in $V$ is contractible in $U$. Any map $f: B^2 \to U$ for which $f(\partial B^2) \subset V$ can be approximated, since $C$ is tame relative to $E^n$, by a map $g: B^2 \to U - C$ such that $g|\partial B^2 = f|\partial B^2$. Furthermore, since $\partial B$ is locally flat at each point of $\partial B - C$, $g$ can be obtained so that $g^{-1}(\partial B)$ consists of a finite number of simple closed curves. The outermost such curves bound pairwise disjoint disks $F_1, \ldots, F_k$ in $B^2$. Now $g|\partial F_i$ can be extended to a map of $F_i$ into $\partial B - C$, from which we can piece together a map $h: B^2 \to U - (C \cup \text{Int } B)$ such that $h|\partial B^2 = f|\partial B^2$. Finally, $h(B^2)$ can be pushed off $B$ to obtain the desired map.

It follows from [11] that the set of points at which $\partial B$ is wild contains no isolated point and hence must be a Cantor set.

Compare Corollary 9 with Corollary 1 of [6].
