GLOBAL BOUNDEDNESS FOR A DELAY DIFFERENTIAL EQUATION\(^1\)

BY

STEPHAN LUCKHAUS

ABSTRACT. The inequality \((\partial_t u - \Delta u)(t, x) \leq u(t, x)(1 - u(t - \tau, x))\) is investigated. It is shown that nonnegative solutions of the Dirichlet problem in a bounded interval remain bounded as time goes to infinity, whereas in a more dimensional domain, in general, this holds only if the delay is not too large.

0. Introduction. The subject of this article is the population dynamics governed by Hutchinson’s equation, i.e. the net reproduction rate is modelled by \(f(u(t), u(t - \tau)) = u(t)(1 - u(t - \tau))\). Here all constants except the delay are normalized to one. For a detailed description see [2]. The question is, does such a law by itself limit the total size of a population if that population is allowed to diffuse.

Suppose that we ask the question a little bit differently, demanding that the population \(u\) reproduce not with the exact rate \(f\) but rather with a rate not exceeding \(f\), unspecified death terms possibly also existing. Then there is the complete answer (for slightly more general \(f\)).

THEOREM. Suppose \(u\) fulfills

\[
\begin{align*}
0 & \leq \partial_t u - \Delta u \leq f(u, u(\cdot - \tau, \cdot)) \quad \text{in } \mathbb{R}^+ \times \Omega, \\
u & = u_0 \quad \text{in } [-\tau, 0] \times \Omega,
\end{align*}
\]

where \(f\) is such that

\[
f(u, v) < u, \quad \lim_{\lambda \to \infty} \frac{1}{\lambda} f(\lambda u, \lambda v) = -\infty \quad \text{f.a. } u, v \in \mathbb{R}^+.
\]

(a) If \(\Omega = [0, L]\) and on \(\partial\Omega\), \(u < \text{const}\) or \(\partial_v u < \text{const}\), then there exists \(K(f, L, \text{const})\) independent of \(u_0\) with

\[
\lim_{t \to \infty} \|u(t, \cdot)\|_{\infty} < K.
\]

(b) If \(n = \dim(\Omega) \geq 2\) and \(u < g\) in \(\partial\Omega\), \(g \in H^\frac{1}{2}_f(\Omega)\), there exists \(\tau(n)\) such that for \(\tau < \tau(n)\) and \(\int_{-\tau}^0 \int_\Omega u_0^2 < \infty\) there is again a constant \(K\) independent of \(u_0\) such that

\[
\lim_{t \to \infty} \int_\Omega u^2(t, \cdot) \leq K.
\]
(b') If in the above case \( \partial_v u < g \) holds in \( \partial \Omega \) instead of \( u < \text{const} \), and \( \Omega \) is locally uniformly Lipschitz—i.e. there is \( \alpha > 0 \) such that for \( x, y \in \partial \Omega \) with \( |x-y| < \alpha, v_x \cdot v_y \geq \alpha - 1 \) holds—then there exists \( \tau(\alpha, n) \) such that for \( \tau < \tau(\alpha, n) \) one again gets a constant \( K \) independent of \( u_0 \) such that

\[
\int_{-r}^{0} \int_{\Omega} u_0^2 < \infty \quad \text{implies} \quad \lim_{t \to \infty} \int_{\Omega} u^2 < K.
\]

(c) On the other hand, given \( n \geq 2, \gamma < 1, f(u,v) = u(1-v) \) there are \( \tau, R > 0 \) and solutions \( u \) of (0) with \( \text{supp } u \subset B_R \) such that

\[
\|u(t,\cdot)\| > e^{\gamma t}.
\]

It should be emphasized that the counterexample (c) shows to what extent the comparison principle fails, since for radially symmetric solutions of (0) in \( B_R \) the one-dimensional result applies, as becomes clear from the proof. So all symmetric solutions stay bounded; still there is also an unbounded solution insofar as the situation differs completely from the otherwise similar equation in [3].

The same kind of theorem can be stated for distributed delays, as becomes clear from the first step of the proof.

The proofs of parts (a) and (b) of the theorem are in two steps. First, in Lemma 1 boundedness for equation (0) is derived once one knows decay estimates for the special equation (1) below, where the support is moving according to the law

\[
u(t,x) \cdot u(t-r,x) = 0.
\]

The appropriate decay estimates are then verified in Lemmas 2 and 3 respectively. The counterexample is also constructed as a function with moving support in Lemma 4.

ACKNOWLEDGEMENTS. I would like to thank R. Pego and B. Fiedler for helpful discussions.

1. Reduction to a problem with undetermined free boundary. Here the problem of getting bounds on solutions of (1) is reduced to getting decay estimates for a simpler equation.

**LEMMA 1.** (a) Suppose \( \Omega \) uniformly locally Lipschitz; i.e. there exists \( \varepsilon > 0 \) such that for \( x, y \in \partial \Omega \) with \( |x-y| < \varepsilon, v_x \geq \varepsilon - 1 \) holds; let \( \tau \in \mathbb{R}^+ \) and suppose that for any solution of

\[
\begin{align*}
\partial_t u - \Delta u &\leq u, 0 \leq u \quad \text{in } (\tau, T) \times \Omega, \\
\partial_v u &\leq 0 \quad \text{in } (0, T) \times \partial \Omega,
\end{align*}
\]

the inequality

\[
\alpha \int_{\Omega} u^2(0,x) \, dx \geq \int_{\Omega} u^2(T,x) \, dx
\]

holds with some \( T > \tau, \alpha < 1 \). Then any solution of

\[
\begin{align*}
\partial_t u - \Delta u &\leq f(u, u(\cdot - \tau, \cdot)), \quad 0 \leq u \quad \text{in } \mathbb{R}^+ \times \Omega, \\
\partial_v u &\leq g \quad \text{in } \mathbb{R}^+ \times \partial \Omega,
\end{align*}
\]
with
\[ \int_{\Omega} u^2(0, x) \, dx < \infty, \quad g \in L_2(\partial \Omega), \]
satisfies
\[ \lim_{t \to \infty} \int_{\Omega} u^2(t, x) \, dx \leq K \]
where \( K = K(f, \varepsilon, \alpha, \tau, \int_{\partial \Omega} g^2) \) does not depend on the initial values.

(b) If \( \Omega \), an arbitrary domain, and \( \tau \in \mathbb{R}^+ \) are such that only for solutions of the Dirichlet problem
\[
\frac{\partial}{\partial t} u - \Delta u \leq u, \quad u \geq 0 \quad \text{in} \quad (0, T) \times \Omega, \\
(1') \quad u(t, x) \cdot u(t - \tau, x) \equiv 0 \quad \text{in} \quad (\tau, T) \times \Omega, \\
\quad u = 0 \quad \text{in} \quad (0, T) \times \partial \Omega,
\]
the decay estimate
\[ \alpha \int_{\Omega} u^2(0, x) \geq \int_{\Omega} u^2(T, x) \]
holds with some \( T > \tau, \alpha > 1 \), then for any solution
\[
\frac{\partial}{\partial t} u - \Delta u \leq f(u, u(\cdot - \tau, \cdot)), \quad 0 \leq u \quad \text{in} \quad \mathbb{R}^+ \times \Omega, \\
(0') \quad u \leq g \quad \text{in} \quad \mathbb{R}^+ \times \partial \Omega,
\]
with \( \int_{\Omega} u^2(0, x) < \infty, \ g \in H^1_0(\Omega) \) we have
\[ \lim_{t \to \infty} \int_{\Omega} u^2(t, x) \, dx \leq K \]
with \( K = K(f, \alpha, T, \|g\|_{1, 2}) \).

PROOF OF (a). First of all we have for any solution \( u \) of (0),
\[
\frac{1}{2} \frac{\partial}{\partial t} \int_{\Omega} u^2 + \int_{\Omega} |\nabla u|^2 \leq \int_{\Omega} u^2 + \sqrt{\int_{\partial \Omega} g^2} \sqrt{\int_{\partial \Omega} u^2}
\]
and
\[
\int_{\partial \Omega} u^2 \leq c_\Omega \left[ \int_{\Omega} |\nabla u|^2 + \int_{\Omega} |u|^2 \right]
\]
so that
\[ \partial_t \int_{\Omega} u^2 \leq 4 \int_{\Omega} u^2 + c_\Omega \int_{\partial \Omega} g^2. \]

Consequently if the theorem does not hold, there has to be a sequence \( u_i \) of solutions of (0) in \((0, T) \times \Omega \) such that
\[ \int_{\Omega} u_i^2(0, x) \, dx =: \lambda_i^2 \uparrow \infty \]
and
\[ \int_{\Omega} u_i^2(T, x) \, dx \geq \frac{1 + \alpha}{2} \lambda_i^2. \]
Consider $v_i := u_i/\lambda_i$. We have
\[
\partial_t v_i - \Delta v_i \leq v_i \quad \text{in } (0, T) \times \Omega,
\]
\[
\partial_n v_i \leq \frac{g}{\lambda_i} \quad \text{in } (0, T) \times \Omega.
\]
As a sequence of positive subsolutions of a parabolic equation, $v_i$ is compact in $L^2$; more precisely, we have $v_i = v_0/\lambda_i + \tilde{v}_i$ where
\[
\partial_t v_0 - \Delta v_0 = v_0 \quad \text{in } (0, T) \times \Omega,
\]
\[
v_0(0, x) \equiv 0 \quad \text{in } \Omega, \quad \partial_n v_0 = g \quad \text{in } (0, T) \times \partial\Omega
\]
and $\tilde{v}$ fulfills
\[
\tilde{v}_i(t, x) \leq e^{\delta t} [E(s) \tilde{v}_i(t-s, \cdot)](x) \quad (\forall 0 \leq s \leq t)
\]
where $E$ is the evolution operator for the heat equation with Neumann boundary values. So for $\tilde{v}_i$ we have the inequality
\[
\int_{T+\delta}^{\tau+T} \int_{\Omega} \tilde{v}_i^2 \leq e^{\delta \int_{\tau+\delta}^{T+T} \int_{\Omega} \left( \frac{2}{\delta} \int_{\delta/2}^{\delta} \int_{\Omega} E(s)(\tilde{v}_i(t-s, \cdot))^2(x) \right)
\]
\[
\leq e^{\delta \int_{\tau+\delta}^{T+\tau-\delta} \int_{\Omega} \tilde{v}_i^2}
\]
where a compact operator of $\tilde{v}_i$ appears in the middle. As a result $\tilde{v}_i$ is a compact sequence in $L^2((\partial, T) \times \Omega)$. Let $\tilde{v} = \lim v_i$ for a subsequence. By (3) we have
\[
1 \geq \lim_{t \to T} \int_{\Omega} v(t)^2, \quad \frac{1 + \alpha}{2} \leq \lim_{t \to T+T} \int_{\Omega} v(t)^2.
\]
Clearly also
\[
\partial_t v - \Delta v \leq 0, v \geq 0 \quad \text{in } (0, T) \times \Omega,
\]
\[
\partial_n v \leq 0 \quad \text{in } (0, T) \times \partial\Omega,
\]
\[
\frac{1}{2} \int_{\Omega} \tilde{v}_i^2(T) + \int_{\tau}^{T} \int_{\Omega} |\nabla \tilde{v}_i|^2
\]
\[
\leq \int_{\Omega} \tilde{v}_i^2(\tau) + \int_{\tau}^{T} \int_{\Omega} \tilde{v}_i^2 + \int_{\tau}^{T} \int_{\partial\Omega} g \tilde{v}_i - \int_{\tau}^{T} \int_{\Omega} \tilde{v}_i \frac{1}{\lambda_i} (1 - f(\lambda_i \tilde{v}_i, \lambda_i \tilde{v}_i(t-\tau, \cdot)))
\]
so that
\[
- \int_{\tau}^{T} \int_{\Omega} \frac{1}{\lambda_i} f(\lambda_i \tilde{v}_i(t), \lambda_i \tilde{v}_i(t-\tau)) \tilde{v}_i \leq \text{const} < \infty
\]
and by going to the limit a.e.
\[
\tilde{v}(t) \tilde{v}(t - \tau) \equiv 0,
\]
a contradiction to (4) in view of the assumption.

The proof of (b) is exactly the same, except that the test function to be used in (1') is $(u - g)_+$ instead of $u$.

**2. Decay estimate in the interval.** By the reduction effected in Lemma 1, part (a) of the theorem is now a consequence of the following estimate.
LEMMA 2. Let \( u \) be a solution of

\[
\begin{align*}
\partial_t u - \partial^2_x u & \leq u, u \geq 0 \quad \text{in } (-\tau, T) \times (0, L), \\
\partial_t u \cdot u(t - \tau, x) & \equiv 0 \quad \text{in } (0, T) \times (0, L), \\
\partial_t u & \leq 0 \quad \text{in } (-\tau, T) \times \{0\} \cup \{L\},
\end{align*}
\]

then

\[
\int_0^L u^2(T) \, dt \leq \int_0^L u^2(0) \leq \exp \left( 2T \left( 1 - \frac{\pi^2}{4L^2} \frac{T^2}{(\tau + T)^2} \right) \right).
\]

PROOF. First in one space dimension we approximate \( u \) by a Lipschitz function \( u_{\varepsilon} \), satisfying the same inequalities as \( u \), and such that \( \partial(\text{supp}(u_{\varepsilon})) \) is a smooth manifold. We continue \( u \) to \( (1 - \varepsilon, L + \varepsilon) \), by reflection and define

\[
\tilde{u}_{\varepsilon, \delta} = \frac{1}{\varepsilon \delta} \int \int dy \, ds \, \xi \left( \frac{t-s}{\delta} \right) \zeta \left( \frac{x-y}{\varepsilon} \right) u(s, y)
\]

and

\[
\tilde{u}_\varepsilon(t, x) = \frac{1}{\varepsilon} \int dy \, \xi \left( \frac{x-y}{\varepsilon} \right) u(t, y)
\]

where \( \xi \in C_0^\infty(\mathbb{R}, \mathbb{R}^+) \), \( \int \xi = 1 \), \( \text{supp}(\xi) \subset B_1(0) \). For \( \tilde{u}_\varepsilon \) we have

\[
\partial_t \tilde{u}_\varepsilon(t, x) \leq c \varepsilon^{-5/2} \sqrt{\int_{B_\varepsilon(x)} u^2(t, y) \, dy}.
\]

Also

\[
u_{\varepsilon}(t, x) \wedge u_{\varepsilon}(t - \tau, x) \leq \frac{1}{\varepsilon} \|\xi\|_\infty \min \left[ \int_{B_\varepsilon(x)} u(t, y), \int_{B_\varepsilon(x)} u(t - \tau, y) \right].
\]

Since \( u(t, \cdot) \cdot u(t - \tau, \cdot) \equiv 0 \), for \( s \) equal to \( t \) or \( s \) equal to \( (t - \tau) \), \( u(s, \cdot) \) has a zero in \( B_\varepsilon(x) \), so by Poincaré’s inequality

\[
\int_{B_\varepsilon(x)} u^2(s, \cdot) < 4 \frac{\varepsilon^2}{\pi^2} \int_{B_\varepsilon(x)} (\partial_x u)^2(s, \cdot).
\]

Consequently

\[
\hat{u}_\varepsilon(t, x) \wedge \hat{u}_\varepsilon(t - \tau, x) \leq c \varepsilon^{1/2}
\]

and

\[
\hat{u}_{\varepsilon, \delta}(t, x) \wedge \hat{u}_{\varepsilon, \delta}(t - \tau, x) \leq c \varepsilon^{1/2} + \delta \varepsilon^{-5/2}.
\]

Now choose \( \delta = \varepsilon^3 \), and also choose an \( \tilde{\varepsilon} \) between \( 2c \sqrt{\varepsilon} \) and \( 4c \sqrt{\varepsilon} \) which is a regular value for \( \hat{u}_{\varepsilon, \varepsilon^3} \). Then for

\[
u_{\varepsilon} := \max(0, \hat{u}_{\varepsilon, \varepsilon^3 - \tilde{\varepsilon}})
\]

we have indeed that \( u_{\varepsilon} \) is Lipschitz, \( u_{\varepsilon}(t - \tau, \cdot) \cdot u_{\varepsilon}(t, \cdot) \equiv 0 \), and \( \partial(\text{supp}(u_{\varepsilon})) \) is a smooth manifold.

It clearly suffices to show the estimate for \( u_{\varepsilon} \).

Take a connected component \( C \) of the interior of \( \text{supp}(u_{\varepsilon}) \) in \( (0, T) \times (0, L) \). We have \( C \cap C - (\tau, 0) = \emptyset \) by assumption, and since \( C \) is bounded and connected in \( \mathbb{R}^2 \) it follows that also \( C \cap C - n(\tau, 0) = \emptyset \).

(The easiest way to see this is as follows: Without loss of generality assume \( \overline{C} \cap \overline{C} - (\tau, 0) = \emptyset \). Take \( (t_1, x_1) \in \overline{C} \) with \( x_1 = \min \{ x, \text{there is } (t, x) \in \overline{C} \} \) and...
(t_2, x_2) \in \bar{C} \text{ with } x_2 = \max\{x, \text{ there is } (t, x) \in \bar{C}\}. \text{ Define } \bar{C} = \bar{C} \cup (t_1, x_1 - R^+) \cup \{t_2, x_2 + R^+\}. \ R^2 \times \bar{C} \text{ has two unbounded components } U^+, U^-; \bar{C} \cap \bar{C} - (\tau, 0) = \emptyset, \text{ so } \bar{C} - (\tau, 0) \subset U^-, \bar{C} - (\tau, 0) \subset U^-\text{, and } \bar{C} - n(\tau, 0) \subset U^--(n-1)(\tau, 0) \subset U^-.

Defining \( C_t = \{x(t, x) \in \bar{C}\} \) we have \( C_t \cap C_{t-n\tau} = \emptyset \) for all \( n \in \mathbb{N} \) or

\[
\int_0^T |C_t| \leq \tau \cdot L \quad \text{if } \tau < T.
\]

We use this inequality, only true in one space dimension, in the Sobolev estimate

\[
\frac{1}{2} \partial_t \left( \int_{C_t} u^2 \right) \leq \int_{C_t} \left( u^2 - |\nabla u|^2 \right) \leq \left( \int_{C_t} u^2 \right) \left( 1 - \frac{\pi^2}{4|C_t|^2} \right).
\]

So we have Jensen's inequality

\[
\int_{C_t} u^2 / \int_{C_0} u^2 \leq \exp \left( 2T \int_0^T \left( 1 - \frac{\pi^2}{4|C_t|^2} \right) \right) \leq \exp \left( 2T \left( 1 - \frac{\pi^2}{4|C_0|^2} \right) \right)
\]

and finally

\[
\int_{C_T} u^2 / \int_{C_0} u^2 \leq \exp \left( 2T \left( 1 - \frac{\pi^2 T^2}{4L^2 \tau^2} \right) \right)
\]

if \( \tau < T \).

This proves the lemma.

3. Decay estimate for arbitrary space dimension.

**Lemma 3.** (a) Suppose

\[
\begin{align*}
\partial_t u - \Delta u &\leq u, 0 \leq u & \text{in } (0, T) \times \Omega, \\
u(t, x) \cdot u(t - \tau, x) &\equiv 0 \quad \text{in } (\tau, T) \times \Omega, \\
\partial_n u &\leq 0 \quad \text{in } (0, T) \times \Omega.
\end{align*}
\]

Suppose \( \partial \Omega \) is locally uniformly Lipschitz, i.e. there exists \( \alpha > 0 \) such that for \( (x, y) \in \partial \Omega \) with \( |x - y| < \alpha \) we have \( \nu_x \cdot \nu_y \geq \alpha - 1 \). Then there exists a constant \( \tau(n, \alpha) > 0 \) such that for \( \tau < \tau(n, \alpha) \),

\[
e^{-\gamma \tau} \int_\Omega u^2(t) < \text{const}
\]

with \( \gamma = \gamma(\tau, n, \alpha) > 0 \).

(b) If \( \Omega \) is arbitrary but \( u = 0 \) in \( \partial \Omega \), the conclusion holds with a constant \( \tau(n) \) depending on dimension only.

**Proof.** We use the following Sobolev estimate in \( \mathbb{R}^n \). If \( \{|u = 0\} \cap B_\rho \cdot |B_\rho|^{-1} > \varepsilon > 0 \), then

\[
\int_{B_\rho} u^2 < C(\varepsilon, n) \rho^2 \int_{B_\rho} |\nabla u|^2.
\]

Consider first case (b); then for any \( t, x \in \Omega \) either

\[
|\{u(t, \cdot) = 0\} \cap B_\rho(x)| \cdot |B_\rho|^{-1} > \frac{1}{2}
\]

or

\[
|\{u(t - \tau, \cdot) = 0\} \cap B_\rho(x)| \cdot |B_\rho|^{-1} > \frac{1}{2}.
\]
On the other hand, 
\[
\int_{B_\rho(x)} u^2(t) - \int_{B_{2\rho}(x)} u^2(t - \tau) \leq \left( \frac{1}{\rho^2} + 1 \right) \int_{t-\tau}^{t} \int_{B_{2\rho}} |u|^2.
\]
So
\[
\int_{B_\rho(x)} u^2(t) \leq \rho^2 C \left( \frac{1}{4}, n \right) \int_{B_{2\rho}(x)} (|\nabla u|^2(t) + |\nabla u|^2(t - \tau))
\]
\[+ \left( \frac{1}{\rho^2} + 1 \right) \int_{t-\tau}^{t} \int_{B_{2\rho}} u^2.
\]
Integrating over \(x\) gives
\[|B_\rho| \int_{\Omega} u^2(t) \]
\[\leq |B_{2\rho}| \left[ \rho^2 C \left( \frac{1}{4}, n \right) \int_{\Omega} (|\nabla u|^2(t) + |\nabla u|^2(t - \tau)) + \left( \frac{1}{\rho^2} + 1 \right) \int_{t-\tau}^{t} \int_{\Omega} u^2 \right],
\]
\[\int_{\Omega} e^{\gamma t} u^2(t) = \int_{\Omega} e^{\gamma s} \int_{t}^{\gamma s} u^2(s) - 2 \int_{t}^{\gamma s} \int_{\Omega} |\nabla u|^2(s)
\]
\[= -2 \int_{\Omega} \left[ 2^{n+1} \rho^2 C \left( \frac{1}{4}, n \right) \int_{\Omega} e^{\gamma t} \int_{t}^{\gamma s} |\nabla u|^2 + e^{\gamma t} \int_{\Omega} \left( 2^n \rho^2 C \left( \frac{1}{4}, n \right) |\nabla u|^2 + 2^n \left( \frac{1}{\rho^2} + 1 \right) e^{\gamma t} |u|^2 \right) \right].
\]
So if one can choose \(\rho\) such that
\[\frac{(\gamma + 2)2^{n+1} \rho^2 e^{\gamma t} C \left( \frac{1}{4}, n \right)}{1 - 2^n e^{\gamma t} (1/\rho^2 + 1)} < 2,
\]
one gets
\[\int_{\Omega} e^{\gamma t} u^2(t) < \text{const}.
\]
It is easily seen that this is the case if \(\tau < 1/2^n e^{\gamma t}\) and
\[8C \tau \left( \frac{\gamma}{2} + 1 \right) < \left( \frac{1}{2^n e^{\gamma t} - \tau} \right)^2.
\]
In case (a) the proof changes only insofar as we have to use the Sobolev estimate (5) in \(\Omega\) instead of \(\mathbb{R}\).

If \(\rho < \alpha\),
\[|\{u = 0\} \cap B_\rho \cap \Omega| |B_\rho \cap \Omega|^{-1} > \varepsilon > 0;
\]
then
\[\int_{B_\rho} u^2 < C(\varepsilon, \alpha, n) \rho^2 \int_{B_\rho} |\nabla u|^2,
\]
and the volume fractions are estimated by
\[|B_{2\rho}(x) \cap \Omega| |B_\rho(x) \cap \Omega|^{-1} \leq C(\alpha, n) \quad \text{for } \rho < \alpha
\]
in inequality (6).
4. The counterexample. As in the decay estimates, for the counterexample we also work with the condition $u(t - \tau, x)u(t, x) \equiv 0$, using the obvious fact that any solution of (1) is also a solution of (0) for $f(u, v) = u(1 - v)$.

**Lemma 4.** Let $\gamma < 1$, $u \geq 2$. Then there exists a ball $B_R \subset \mathbb{R}^N$ and a delay $\tau \in \mathbb{R}^+$ such that a solution of

$$
\partial_t u - \Delta u \leq u, 0 \leq u \quad \text{in} \quad \mathbb{R}^+ \times B_R,
$$

$$
\frac{u(t - \tau, x) \cdot u(t, x)}{u(t, x)} \equiv 0 \quad \text{in} \quad (\tau, \infty) \times B_R
$$

with $\text{supp}(u) \subseteq B_R$ can be constructed which grows like $\int_{B_R} u > e^{\gamma t}$.

**Proof.** The idea is to prescribe first $\text{supp}(u)$, which will be a ball $B_r$ moving spirally in $B_R$, and then to solve the Dirichlet problem for $\partial_t u - \Delta u = u$ in that moving domain. If $r$ is large enough and the movement slow enough, the first eigenvalue of that problem will be as close to 1 as we please. Starting then with the first eigenfunction as initial value and extending $u$ by zero to all of $B_R$, one gets the desired counterexample.

So take a point $x_0$ in $B_R$ with coordinates $(\rho \cos \phi, \rho \sin \phi, 0, \ldots, 0)$ and move it with constant angular velocity $c$. Solving $\partial_t u - \Delta u = u$ in $B_r(x(t))$ is then the same as solving

$$
\partial_t u - c\partial_1 u x_2 + c\partial_2 u x_1 - \Delta u = u
$$

in $B_r(x_0)$. For $c\rho$ small and $r$ large the first eigenvalue of this operator is arbitrary near 1. But that makes $\tau$ large as the condition $u(t, x) \cdot u(t - \tau, x)$ identically zero is fulfilled for $1 - \cos(c\tau) \geq r/\rho$.
