TRAVELING WAVES IN COMBUSTION PROCESSES WITH COMPLEX CHEMICAL NETWORKS

STEFFEN HEINZE

Abstract. The existence of traveling waves for laminar flames with complex chemistry is proved. The crucial assumptions are that all reactions have to be exothermic and that no cycles occur in the graph of the reaction network. The method is to solve the equations first in a bounded interval by a degree argument and then taking the infinite domain limit.

0. Introduction. In this paper we establish the existence of traveling waves for premixed laminar flames with complex chemical networks. We consider the case of vanishing Mach number i.e. the flame speed is much smaller than a typical gas velocity.

The resulting equations were solved by H. Berestycki, B. Nicolaenko, B. Scheurer [1] for a single step irreversible reaction. Here we discuss a class of exothermic acyclic chemical networks. In [2, 3] P. Fife and B. Nicolaenko used a somewhat weaker condition on the network than ours for a formal asymptotic analysis in the limit of high activation energy. For mathematical reasons we can only handle the case of exothermic, i.e. irreversible reactions.

In the first section we introduce the notations and derive the traveling wave equations from the thermodynamic conservation laws. In §2 these equations are solved in a finite domain by a mapping degree argument and then shown to converge in the infinite domain limit.

The third section treats some examples to which the existence theorem can be applied.

1. Notations and derivation of the traveling wave equations. Let $Y_j$ be the mass functions of $n$ chemical species $A_j$ reacting in an infinite tube and depending on time $t$ and one space variable $\xi$. A chemical network consisting of $r$ reactions may be symbolically written as

$$R_j : \sum_{i=1}^n v_{ij} A_i \rightarrow \sum_{i=1}^n \mu_{ij} A_i,$$

where $v_{ij}, \mu_{ij} \in \mathbb{N} \cup \{0\}$ represent the stoichiometric coefficients and for every $j$ there exist $i$ and $k$ with $v_{ij}, \mu_{kj} > 0$. Each reaction proceeds at a rate

$$\omega_j = \rho \prod_{i=1}^n Y_i^{v_{ij}} B_j(T) \exp\left(-\frac{E_j}{RT}\right).$$

Here $T$ is the absolute temperature, $E_j$ the activation energy, $R$ the gas constant and $B_j(T) > 0$ for $T > 0$. The mass action law gives the product over the mass fractions and the Arrhenius kinetic the exponential factor. Next we introduce some notation. Let

$$U = (T, Y_1, \ldots, Y_n) \in \mathbf{R}^{n+1},$$

$$Q_j = \text{heat release of reaction } j,$$

$$d_0(U) = \text{heat conductivity},$$

$$d_i(U) = \text{diffusion coefficient of species } i,$$

$$\rho = \text{density},$$

$$p = \text{pressure},$$

$$D = \frac{\partial}{\partial t} + v \frac{\partial}{\partial \xi} = \text{convective derivative with } v \text{ as the velocity},$$

$$c_p = \text{specific heat at constant pressure}.$$

Using the notations

$$F_0(U) = \sum_{j=1}^{r} Q_j \omega_j(U),$$

$$F_i(U) = \sum_{j=1}^{r} (\mu_{ij} - v_{ij}) \omega_j(U),$$

the balance laws of mass, momentum, energy and mass fractions for zero Mach number and no viscosity can be written in the form

\begin{equation}
\frac{Dp}{Dt} + \rho \frac{Dv}{Dt} = 0,
\end{equation}

\begin{equation}
\rho \frac{Dv}{Dt} = 0 \Rightarrow \frac{\partial p}{\partial \xi} = 0,
\end{equation}

\begin{equation}
\rho c_p \frac{DT}{Dt} - \frac{\partial}{\partial \xi} \left( d_0 \frac{\partial T}{\partial \xi} \right) = F_0(U),
\end{equation}

\begin{equation}
\rho \frac{DY_i}{Dt} - \frac{\partial}{\partial \xi} \left( d_i \frac{\partial Y_i}{\partial \xi} \right) = F_i(U).
\end{equation}

Additionally the state equation for an ideal gas holds:

\begin{equation}
p = R \rho T
\end{equation}

This approximation implies a constant pressure.

For the description of a flame moving to the left with constant velocity $v_0$ let $x = \xi + v_0 t$ be the single independent variable. (1.2.a) then gives with $d/dx = (\cdot)'$

$$v_0 \rho' + (\rho v)' = 0 \quad \text{or} \quad \rho(v_0 + v) = c$$

Here $c$ is the mass flux. If (1.2.d) is substituted in (1.2.c) and $B_j(T)$ is redefined by $(p/RT) B_j(T)$ one arrives at

\begin{equation}
-(d_0 T')' + c T' = F_0(U),
\end{equation}

\begin{equation}
-(d_i Y_i')' + c Y_i' = F_i(U).
\end{equation}

Notice that $\rho$ disappears after scaling.
Introduce the reaction vector \( V_j = (\mu_{1j} - \nu_{1j}, \ldots, \mu_{nj} - \nu_{nj}) \) and let \( K_j = (Q_j, V_j) \). Now (1.3) may be written in the vector form

\[
-(D(U)U')' + cU' = F(U)
\]

where \( D = \text{diag}(d_0, \ldots, d_n) \) and \( F = (F_0, \ldots, F_n) \). For a detailed formal derivation from the thermodynamic conservation laws see [5]. As boundary conditions we prescribe \( T^+ = T(-\infty) > 0 \) and \( Y^+ = Y_j(-\infty) \geq 0 \) where not all \( Y_j^+ \) vanish.

Since we consider only exothermic reactions \( U^- \) is in general not an equilibrium point of (1.4), i.e. \( F(U^-) \neq 0 \). Therefore we introduce an artificial ignition temperature \( \theta > T^- \) and redefine \( F(U) \) as 0 for \( T < \theta \). This cutoff of \( F \) is discussed in [1].

\( F \) is now discontinuous and (1.4) should hold in the following sense

\[
-D(U)U' + c(U - U^-) = \int_{-\infty}^{x} F(U(s)) \, ds
\]

with \( U \in C^1(\mathbb{R}) \). At \( x = +\infty \) we demand \( U = U^+ \) with \( T^+ > \theta \). Hence \( F(U(s)) \) is \( C^1 \) near infinity and \( F(U^+) = 0 \) must hold. (1.5) gives the compatibility condition

\[
c(U^+ - U^-) = \int_{-\infty}^{\infty} F(U(s)) \, ds.
\]

Given \( U^- \) we seek a positive solution of (1.5) for some \( c \) and \( U^+ \).

2. The main existence theorem. With the notations of §1 we state

**THEOREM 1.** Suppose that the following assumptions hold:

(i) Let \( U^- \in \mathbb{R}_{+0}^{n+1} = \{ U \in \mathbb{R}_{+0}^{n+1}, U_j > 0, i = 0, \ldots, n \} \) be given. Assume \( U_0^- > 0 \) and that there exists \( j^* \) such that \( v_{i,j^*} > 0 \) implies \( u_{i,j^*}^- > 0 \).

(ii) The ignition temperature \( \theta \) should satisfy \( 0 < \theta - U_0^- \leq R \) where \( R \) is a constant which depends only on \( U^- \) and \( K_j \).

(iii) The reaction rates have the form

\[
\omega_j(U) = \begin{cases} 
\prod_{i=1}^{n} U_i^{s_{ij}} B_j(U_0) \exp(-E_j/U_0) & \text{for } U_0 > \theta, \\
0 & \text{for } U_0 < \theta.
\end{cases}
\]

(iv) All reactions are exothermic, i.e. \( Q_j > 0 \).

(v) For the reaction vectors \( V_j \) there exists \( L \in \mathbb{R}_{+0}^n \), such that \( L \cdot V_j < 0 \) for \( j = 1, \ldots, r \).

(vi) The diffusion coefficients \( d_i(U) \) are differentiable in \( \{ U \in \mathbb{R}_{+0}^{n+1}, U_0 \geq U_0^- \} \) and strictly positive for \( U \) bounded.

Then there exists \( c > 0 \); \( U^+ \in \mathbb{R}_{+0}^{n+1} \) and a function \( U \in C^2(\mathbb{R} \setminus \{0\}) \cap C^1(\mathbb{R}) \) with values in \( \mathbb{R}_{+0}^{n+1} \) such that

\[
-(D(U)U')' + cU' = F(U) \quad \text{in } \mathbb{R} \setminus \{0\},
\]

\[
U(-\infty) = U^-; \quad U(+\infty) = U^+; \quad U_0(0) = \theta,
\]

\( U_0'(x) > 0 \).

Furthermore \( U^+ \) satisfies \( F(U^+) = 0 \) and there exist \( \alpha_j \geq 0 \), \( j = 1, \ldots, r \), with

\[
U^+ = U^- + \sum_{j=1}^{r} \alpha_j K_j.
\]
Remarks on the assumptions. (i) guarantees the positivity of at least one reaction rate.

(ii) is needed for the estimate of $c$ from below. It is also reasonable to choose $\theta - U_0$ small to diminish the cutoff error in $\omega_j$.

(iv) yields the monotonicity of $U_0$, which implies the existence of $\lim_{x \to -\infty} U(x)$.

(v) gives a priori bounds for $U$.

(v) is equivalent to the following (see Proposition 6): $\alpha_j > 0$ and $\sum_{j=1}^m \alpha_j V_j \in \mathbb{R}_{>0}$ imply $\alpha_j = 0$. In [2, 3] the weaker condition $\sum_{j=1}^m \alpha_j V_j = 0$ is used for an asymptotic analysis at high activation energy. But the network $A \to 2B; B \to 2A$ shows the nonexistence of a boundary condition $U^+$ with the necessary conditions (2.2), (2.3). Reaction cycles are characterized by the existence of $\alpha_j > 0$ where not all $\alpha_j$ vanish, s.t. $\sum_{j=1}^m \alpha_j K_j = 0$; but the latter is excluded by (v). This seems reasonable because we consider only exothermic reactions.

Further remarks. (a) Besides positivity and differentiability for $U_0 > \theta$ we need no condition on the temperature dependence of the reaction rates $\omega_j$.

(b) If $U^-$ is given $U^+$ is in general not unique (compare the examples in §3). Also if only one $U^+$ is possible no uniqueness of $c$ or $U^+$ is asserted.

Summary of the proof. (1.5) is first solved in a bounded domain with “false” boundary conditions to insure that the temperature is monotone increasing. A priori estimates establish the infinite domain limit. The monotonicity of $U_0$ gives the existence of $\lim_{x \to -\infty} U(x) = U^+$ with the properties in (2.2), (2.3).

Solution in a finite domain. In the interval $(-a, a)$ we seek a positive solution of

$$-D(U)U' + c(U - U^-) = \int_{-a}^x F(U(s)) \, ds$$

with boundary conditions

$$-D(U)U' + cU = cU^- \quad \text{at } x = -a,$$

$$U(a) = U^+, \quad U_0(0) = \theta,$$

where

$$U_i^{a^-} = \begin{cases} U_i^- & \text{if } U_i^- > 0, \\ \frac{1}{a} & \text{if } U_i^- = 0, \end{cases}$$

and

$$U_0^{a^+} > \theta \quad \text{will be chosen later independent of } a,$$

$$U_i^{a^+} = 0 \quad \text{for } i = 1, \ldots, n.$$
Suppose another \( x_1 < x_0 \) with \( U_0(x_1) = \theta \). Because of (2.8) \( x_1 \) may be chosen maximal and \( U_0(x) < \theta \) holds in \((x_1, x_0)\). From \( F(U(x)) \equiv 0 \) in \((x_1, x_0)\) it follows that \( U_0(x) \equiv \theta \) in \((x_1, x_0)\), a contradiction. □

By shifting \( U_0 \) we may assume \( \theta = 0 \) and \( U_0^{-} < 0 \). According to the proposition the problem is reduced to finding a function \( U \in C^2(I, \mathbb{R}^{n+1}) \) in the interval \( I = (0, a) \) such that

\[
-(D(U)U')' + cU' = F(U) \quad \text{in } I,
\]

\[
-D(U)U' + c(U - U^{-}) = 0 \quad \text{at } x = 0,
\]

\[
U(a) = U^+, \quad U_0(0) = 0.
\]

Next we construct a compact operator, whose fixed points are the solutions of (2.9).

Let \( R > 0 \) and \( \Omega_R \) be the following open subset of \( C^1(\bar{I}, \mathbb{R}^{n+1}) \):

\[
\Omega_R := \{ U \in C^1(\bar{I}, \mathbb{R}^{n+1}): |U|_{C^2(I)} < R; U_i > 0 \text{ on } I \text{ for all } i; U_0(0) = 0; U'_0(0) > 0; U_0(a) > 0; U'_0(a) > 0; U'_0(a) < 0 \text{ for } i \geq 1 \}.
\]

Assumption (vi) in Theorem 1 gives a constant \( a(\Omega_R) \) s.t. \( d_i(U) \geq a > 0 \) for all \( U \in \Omega_R \). Define \( D_i(U) := tD(U) + a(1 - t)1, 0 \leq t \leq 1 \), with \( 1 \) the unit matrix. Further let \( 0 < \zeta < \bar{\zeta} \). For \( W \in \bar{\Omega}_R, c \in [\zeta, \bar{\zeta}] \) we define

\[
K_i(W, c) := (U + c + W_0(0))
\]

where \( U \) is a solution of the linear boundary value problem

\[
-(D_i(W)U')' + cU' = tF(W) \quad \text{in } I,
\]

\[
-D_i(W)U' + cU = cU^{-} \quad \text{at } x = 0,
\]

\[
U(a) = U^+.
\]

It is easy to check that \( K_i \) is well defined, continuous and compact with values in \( C^1(I, \mathbb{R}^{n+1}) \times \mathbb{R} \). Observe that the fixed points of \( K_1 \) have the desired properties. Now a priori estimates are given to insure that \( K_i \) has no fixed points on \( \partial(\Omega_R \times (\zeta, \bar{\zeta})) \) for suitable \( R, \zeta \) and \( \bar{\zeta} \).

**Proposition 2.** Let the assumptions of Theorem 1 hold. If \( U_0^{a+} \) is sufficiently large then there exist constants \( R, \zeta, \bar{\zeta} \) s.t. \( K_i \) has no fixed point on \( \partial(\Omega_R \times (\zeta, \bar{\zeta})) \) for \( 0 \leq t \leq 1 \). In particular \( (U, c) \in \bar{\Omega}_R \times [\zeta, \bar{\zeta}] \) and \( K_i(U, c) = (U, c) \) imply \( |U|_{C^1(I)} < R; U(x) \in \mathbb{R}^{n+1} \) for all \( x \in I \) and \( \zeta < c < \bar{\zeta} \). Additionally we have for \( t = 1 \) that \( |U|_{C^2(I)} \) and \( \bar{\zeta} \) are bounded independent of \( a > a_0 \). Furthermore \( U_0^+(x) > 0 \) holds.

**Proof.** Assume that \( (U, c) \) is a fixed point of \( K_i \) in \( \bar{\Omega}_R \times [\zeta, \bar{\zeta}] \). We have to prove that \( (U, c) \in \Omega_R \times (\zeta, \bar{\zeta}) \) for suitable \( R, \zeta, \bar{\zeta} \) and \( U_0^{a+} \). For fixed \( R \) assumption (vi) in Theorem 1 gives that \( d_i(U) \) is uniformly positive. Hence the maximum principle can be applied. We divide the proof into several steps.

(i) First we verify the positivity of \( U_i \) in \( I \) and the boundary conditions specified in \( \Omega_R \). Proposition 1 gives \( U_0(x) > 0 \) in \( I \). From (2.7), (2.9) we get \( U_0(0) = 0; U'_0(0) > 0; U_0(a) > 0; F(U) \) is continuous for \( U_0 > 0 \) and hence

\[
-(D(U)U')' + cU' = tF(U)
\]
Now let \( i \geq 1 \). If \( V_{ij} := \mu_{ij} - v_{ij} \) is negative then \( v_{ij} > 0 \) and \( \omega_j(U) \) contains \( U_i \) as a factor. So \( F_i(U) \) may be decomposed as

\[
F_i(U) = -h_i(U)U_i + \sum_{V_{ij} > 0} V_{ij}\omega_j(U)
\]

with \( h_i(U) = -(1/U_i)\sum_{V_{ij} < 0} V_{ij}\omega_j(U) \) positive because \( U_i \geq 0 \). From (2.11) we derive

\[
(\frac{d}{dt}(U)U_i)' - cU_i' - th_i(U)U_i \leq 0.
\]

The maximum principle gives \( U_i > 0 \) in \( I \) and \( U_i'(a) < 0 \) because \( U_i \equiv \text{constant} \) would violate the boundary conditions in (2.9). \( U_i(0) > 0 \) follows now from the b.c. at \( x = 0 \).

(ii) Next we derive an upper bound for \( |U| \). By Theorem 1(v) there exists a vector \( L \in \mathbb{R}^{n+1}_+ \) such that \( L \cdot V_j < 0 \), \( j = 1, \ldots, r \). Hence \( L_0Q_j + L \cdot V_j \leq 0 \) for some \( L_0 > 0 \), i.e. \( (L_0, L) \cdot K_j = 0 \) and \( (L_0, L) \cdot F(U) \leq 0 \). Multiply (2.11) by \( (L_0, L) \) and integrate:

\[
\sum_{i=0}^n L_i d_i U_i' \geq c \sum_{i=0}^n L_i(U_i - U_i^{a-}) \quad \text{in} \quad I.
\]

Choose now \( U_0^{a-} > U_0^- + (1/L_0)\sum_{i=1}^n L_i U_i^{a-} \) and use \( U_i(a) = 0; \ U_i'(a) \leq 0 \) for \( i = 1, \ldots, n \) to conclude that \( U_i'(a) > 0 \).

Observe that \( U_0^{a+} \) is independent of the domain if \( a > a_0 \). If we would have \( U_0'(x_0) = 0 \) for some \( x_0 \in I \) then the equation for \( U_0 \) would imply \( U_0''(x_0) < 0 \) and thereof \( U_0' < 0 \) in \( (x_0, a) \) which contradicts \( U_0'(a) > 0 \). Thus \( U_0' > 0 \) and \( 0 < U_0 < U_0^{a+} \) in \( I \). Using the monotonicity of \( U_0 \) we get

\[
c(U_0^{a+} - U_0^-) \geq -d_0 U_0'(x) + c(U_0(x) - U_0^-) = t \int_0^x F_0(U(s)) \, ds
\]

and for \( \alpha > 0 \) it follows with some \( R_1 > 0 \):

\[
-d_0 U_i' + c(U_i - U_i^{a-}) = t \int_0^x F_i(U(s)) \, ds \leq cR_1
\]

since \( F_i \) is a linear combination of \( \omega_j \). This and \( U_i(a) = 0 \) give

\[
|U|c_{\alpha I} \leq \max_{1 \leq i \leq n} (U_i^{a-} + R_1, U_0^{a+}) =: R_2
\]

independent of \( a \) for \( a > a_0 \).

We remark that \( R_2 \) depends only on \( U_0^{a+} \) and \( K_j \). Now choose constants such that for all \( U \in \{ U \in \mathbb{R}^{n+1}_+; |U| < R_2 \}, 0 < \alpha \leq d_i(U) \leq \beta; |\nabla U|d_i| \leq \gamma; |F(U)| \leq M \) holds. Since \( R_2 \) is independent of \( \Omega_R \times [\bar{c}, \bar{c}] \) so are the other constants.

(iii) Now we prove a \( C^2 \)-estimate for \( U \). From \( -D_i(U)U_i' + c(U - U_i^{a-}) = t \int_0^x F_i(U(s)) \, ds \) we obtain

\[
|U'| \leq (1/\alpha)c(R_2 + R_1 + |U_i^{a-}|^0) =: cR_3
\]

and from (2.11)

\[
|U''| \leq (1/\alpha)c(R_2^2 + c^2R_1^2 + cM) =: R_4(c).
\]
(iv) To derive an upper bound for $c$ let $w(x) = U_0^- - U_0(x)$ and apply the lemma of Gronwall [7] to

$$-d_0 U_0' + c(U_0 - U_0^-) \leq tMx$$

and conclude

$$w(a) \leq w(0)e^{c_\alpha/\beta} + \frac{tM}{\alpha} \int_0^a se^{c/\beta(a-s)} \, ds.$$  

Thus

$$-U_0^- e^{c_\alpha/\beta} \leq U_0^{a^+} - U_0^- + \left( \frac{M\beta^2}{\alpha c^2} \right) e^{c_\alpha/\beta} \quad (U_0^- < 0).$$

If $c^2 > -2M\beta^2/\alpha U_0^- =: c_1^2$ then

$$-\frac{U_0^-}{2e^{c_\alpha/\beta}} \leq U_0^{a^+} - U_0^- \quad \text{or} \quad c \leq \frac{\beta}{a} \ln \left( \frac{2U_0^{a^+} - U_0^-}{-U_0^-} \right) =: c_2.$$

Now choose $\tilde{c} > \max(c_1, c_2)$ and $R > R_2 + R_3\tilde{c}$. Observe that for $t = 1$ and $a > a_0$ one can estimate $c$ and consequently the $C^2$-norm of $U$ independently of $a$.

(v) Concerning the lower bound for $c$ use $F_0(U) > 0$ and Gronwall’s Lemma applied to $-d_0(U)U' + c(U - U^-) \geq 0$ to get

$$U_0^{a^+} - U_0^- \leq -e^{c_\alpha/\beta} U_0^- \quad \text{or} \quad c \geq \frac{\alpha}{a} \ln \left( \frac{U_0^{a^+} - U_0^-}{-U_0^-} \right) > : \zeta > 0$$

which gives all the desired estimates. □

Next we use the mapping degree to show that $K_1$ has a fixed point.

**Proposition 3.** There exist $U_0^{a^+}$ such that for any given domain $I = (0, a)$ the problem (2.8) has a solution $(U, c) \in C^2(I, R_{++}^1) \times R_+^1$.

**Proof.** Take $\Omega_R \times (\zeta, \tilde{c})$ as above. By Proposition 2, $\deg(id, \Omega_R \times (\zeta, \tilde{c}) - K_1(\cdot, \cdot))$ with respect to $(0, 0) \in C^1(I) \times R$ is independent of $t$. The degree of $id - K_0$ is easily seen to be 1. Consequently $K_1$ has a fixed point. □

**The infinite domain limit.** Let $(U_a, c_a)$ be a solution of (2.9) in $(0, a)$. According to Proposition 2 there exist $R, \tilde{c} > 0$ such that $|U_a|_{C^2((0, a))} < R$ and $0 < c_a < \tilde{c}$ independent of $a$ for $a > a_0$.

It remains to bound $c_a$ from below independent of $a$.

**Proposition 4.** Under the assumptions of Theorem 1 let $(U_a, c_a)$ be a solution of (2.9) in $(0, a)$. If $U_0^{a^+}$ is sufficiently large then $c_a > \zeta > 0$ for all $a > a_0$.

**Proof.** In the proof we omit the subscript $a$. Since $U_0' > 0$ and $F_0(U) \geq 0$ we get from (2.9)

$$\int_0^a F_0(U(s)) \, ds \leq c(U_0^+ - U_0^-), \quad 0 \leq \alpha U_0' \leq d_0(U)U'_0 \leq c(U_0^+ - U_0^-).$$

This yields with $U_0$ as the independent variable

$$\int_{U_0^-}^{U_0^+} F_0(U(U_0)) \, dU_0 \leq c_4^2(U_0^+ - U_0^-)^2.$$
Thus it suffices to estimate $F_0(U(U_0))$ on a fixed $U_0$-interval from below. For that purpose we estimate one $\omega_j$. Choose $j^*$ according to assumption (i) in Theorem 1 and consider $i$ with $\nu_{i,j^*} > 0$. Hence $U_i^{ij^*} = U_i^j > 0$. Let $V_{ij}$ be the $i$th component of $V_j$. Since $Q_j > 0$ we can find $\tilde{L}_i$ for all such indices $i$ with $Q_j + \tilde{L}_i V_{ij} \geq 0$ and therefore $F_0(U) + \tilde{L}_i f_i(U) \geq 0$. Now add to the equation for $U_0$ the equation for $U_i$ multiplied by $\tilde{L}_i$ and integrate:

$$d_0 U_0' + \tilde{L}_i d_i U_i' \leq c(U_0 - U_0^- + \tilde{L}_i (U_i - U_i^-))$$

or

$$d_0 U_0' + \tilde{L}_i (d_i U_i)' \leq c(U_0 - U_0^- + \tilde{L}_i (U_i - U_i^-)) + \tilde{L}_i (\nabla U_i' - U')U_i$$

$$\leq c(U_0 + (\tilde{L}_i (1 + \gamma R_3)/\alpha) d_i U_i - U_0^- - \tilde{L}_i U_i^-) = cW$$

where $\gamma$, $\alpha$, $R_3$ are as in the proof of Proposition 2. With $U_0' > 0$ and $\alpha/(1 + \gamma R_3) \leq d_0(U)$ we get

$$\frac{\alpha}{1 + \gamma R_3} W' = \frac{\alpha}{1 + \gamma R_3} U_0' + \tilde{L}_i (d_i U_i)' \leq cW.$$ 

Now choose $U_0^+ \geq U_0^- + \tilde{L}_i U_i^-$ for all $i$ with $\nu_{i,j^*} > 0$. Since $U_i(a) = 0$ we have $W(a) > 0$ and by (2.12) $W(x) \geq 0$ throughout $[0, a]$. Hence

$$U_i(x) \geq \frac{\alpha}{\beta(1 + \gamma R_3)} \frac{(U_0^- + \tilde{L}_i U_i^- - U_0(x))}{\tilde{L}_i}.$$ 

Now let $-U_0^- < \tilde{L}_i U_i^-$ for all $i$ with $\nu_{i,j^*} > 0$ (see Theorem 1(ii)). Thus $U_i$ is bounded from below by a positive function of $U_0$ on the $U_0$-interval $[0, \min_{\nu_{i,j^*} > 0} \tilde{L}_i U_i^- + U_0^-]$. So the same is true for $\omega_j(U)$ and $F_0(U)$ and we are done. Now we can pass to the limit $a \to \infty$. □

**Proposition 5.** Problem (2.1) has a nonnegative solution $U \in C^2(\mathbb{R} \setminus \{0\}) \cap C^1(\mathbb{R})$ such that $\lim_{x \to \infty} U(x) =: U^+$ exists and for which (2.2), (2.3) is satisfied. Furthermore $U_0' > 0$ holds.

**Proof.** The $C^2$-norm of a solution $U^a$ in the finite domain $(0, a)$ is uniformly bounded. So by selecting a subsequence, as $a \to \infty$ $U_a$ converges to $U$ locally uniformly in $C^1(\mathbb{R}, \mathbb{R}^{n+1})$ and $c^a \to c > 0$ since $c < c^a < \tilde{c}$.

$U$ satisfies the boundary condition at $x = 0$ by (2.6) $U_0'(0) > 0$ and $U_0'(x) \geq 0$ imply $U_0(x) > 0$ in $\mathbb{R}^+$. Hence $F(U)$ is continuous and

$$\int_0^\infty F(U^a(s)) ds \to \int_0^\infty F(U(s)) ds$$

for any fixed $x$ as $a \to \infty$.

So $U$ solves the integrated equation (1.5) and by continuity of $F(U)$ also (2.9). Therefore $U \in C^2(\mathbb{R}^+, \mathbb{R}^{n+1})$.

The maximum principle gives $U_i > 0$ whenever $U_i^- > 0$. Since $U_0$ is bounded, nondecreasing and $U_0'(0) > 0$ $\lim_{x \to \infty} U_0(x) =: U_0^+ > U_0(0) = 0$ exists.

Let $W := D(U)U'$ and $\Gamma$ the $\omega$-limit set of $(U, W)$. Note that

$$\Gamma \subset \left\{ \left( \tilde{U}, \tilde{W} \right) \in \mathbb{R}^{2n+2} : \tilde{W} = U_0^+, \tilde{U} \geq 0 \right\}.$$
travelling waves in combustion processes

\[ \dot{U}' = D(\dot{U})^{-1}\dot{W}, \quad \dot{W}' = cD(\dot{U})^{-1}\dot{W} - F(\dot{U}) \]

\( \dot{U}_0 = U^+_0 \) gives \( \dot{W}_0 = \dot{W}_0 = 0 \), \( F_0(\dot{U}) = 0 \) and consequently \( \omega_j(\dot{U}) = 0 \) for all \( j \). Since \( F_i \) is a linear combination of \( \omega_j \), \( F_i(\dot{U}) \) vanishes for all \( i \). Thus the only bounded solution of (2.13) in \( \Gamma \) is \( \dot{U} = \text{constant} \) and \( \dot{W} = 0 \). Hence \( \lim_{x \to \infty} U(x) = U^+ \) exists and \( \lim_{x \to \infty} U'(x) = 0 \). \( F(U^+) = 0 \). From the equation for \( U_0 \) we conclude

\[ \int_0^\infty F_0(U(s)) \, ds = c(U_0^+ - U_0') \]

and \( \int_0^\infty \omega_j(U(s)) \, ds = :\alpha_j c \) exists with \( \alpha_j \geq 0 \). Thus \( U^+ = U^- + \sum_{j=1}^r \alpha_j K_j \).

Now if \( U^- > 0 \) for \( i > 1 \) the maximum principle applied to any finite interval gives \( U_i(x) > 0 \); so at least \( \omega_j(U(s)) > 0 \) where \( j^* \) is as in Theorem 1(i) and consequently \( F_0(U(s)) > 0 \). If \( U_0''(x) = 0 \) for some \( x \) then \( U_0''(x) = 0 \) since \( U_0 \) is nondecreasing. This contradicts \( F_0(U) > 0 \). Hence \( U_0 \) is strictly monotone increasing. For solving the equation in \( (-\infty, 0) \) take \( U(0), U'(0) \) of the solution in \( (0, \infty) \) as initial data. Since \( F(U) = 0 \) for \( x < 0 \) it is easy to see that \( \lim_{x \to -\infty} U = U^- \) and \( U_i > 0 \) holds. This completes the proof of Theorem 1. \( \Box \)

3. Simple existence criteria and examples. First we will give some equivalent conditions to Theorem 1(v), in order to characterize the class of admissible chemical networks.

**Proposition 6.** Let \( V_1, \ldots, V_r \in \mathbb{R}^n \setminus \{0\} \). Then the following conditions are equivalent:

(i) There exists a vector \( L \in \mathbb{R}^{n+1} \) such that \( L \cdot V_j < 0 \) for all \( j = 1, \ldots, r \).

(ii) \( \alpha_j > 0 \), \( j = 1, \ldots, r \), and \( \sum_{j=1}^r \alpha_j V_j \in \mathbb{R}_{\geq 0}^{n+1} \) imply \( \alpha_j = 0 \), \( j = 1, \ldots, r \).

(iii) Let \( C \) the positive cone spanned by \( V_j \) and \( -C \) the negative cone. Then \( C \cap \mathbb{R}_{\geq 0}^{n+1} = \{0\} \) and \( C \cap -C = \{0\} \).

**Proof.** (i) \( \implies \) (ii). Multiply \( \sum_{j=1}^r \alpha_j V_j \) by \( L \) and conclude \( \alpha_j = 0 \).

(ii) \( \implies \) (iii). Let \( X \in C \cap \mathbb{R}_{\geq 0}^{n+1} \) i.e., \( X = \sum_{j=1}^r \alpha_j V_j \in \mathbb{R}_{\geq 0}^{n+1} \) with \( \alpha_j \geq 0 \). Then (ii) gives \( \alpha_j = 0 \).

Let \( X \in C \cap -C \), i.e., \( X = \sum_{j=1}^r \alpha_j V_j = -\sum_{j=1}^r \beta_j V_j \), with \( \alpha_j, \beta_j \geq 0 \). Hence \( \sum_{j=1}^r (\alpha_i + \beta_j)V_j = 0 \) and \( \alpha_i = \beta_j = 0 \) follows from (ii).

(iii) \( \implies \) (i).

(iii) implies the existence of a \( n - 1 \) dimensional hyperplane that separates \( C \) and \( \mathbb{R}_{\geq 0}^{n+1} \) strictly. A normal vector \( L \) to this hyperplane may be chosen such that \( L \cdot X < 0 \) for \( X \in C \setminus \{0\} \) and \( L \cdot X > 0 \) for \( X \in \mathbb{R}_{\geq 0}^{n+1} \setminus \{0\} \). By setting \( X = V_j \) and \( X \) the basis vectors in \( \mathbb{R}^n \) respectively we obtain (i). \( \Box \)

**Remarks.** (a) (ii) is the dual condition to (i); cf. the Fredholm-alternative for systems of inequalities. (ii) means that we cannot have reaction chains in the graph of the network whose beginning is part of its end. As an example the network

A \( \rightarrow \) 2B; B \( \rightarrow \) 4 or as a chain A \( \rightarrow \) 2B \( \rightarrow \) 4 is excluded.
As a special case reaction cycles are not admissible.

(b) The networks \( A \to B; B \to A \) and \( A \to 2B; B \to 2A \) show that in general no condition in (iii) can be omitted. In this sense the condition is also necessary for exothermic networks.

Simple examples. For some simple reaction mechanisms, which occur as parts in many networks we check the above conditions for existence and give the possible boundary conditions \( U^+ \). \( U^+ \) satisfies \( F(U^+) = 0; \ U^+ \in \mathbb{R}^{n+1}_{>0} \), and \( U^+ = U^- + \sum_{j=1}^{n} \alpha_j K_j \) for some \( \alpha_j > 0 \).

(a) Sequential reaction.

\[
A_1 \xrightarrow[R_1]{} A_2 \xrightarrow[R_2]{} \cdots \xrightarrow[R_n]{} A_n.
\]

This gives

\[
V_j = (0, \ldots, 0, -1, 1, 0, \ldots, 0) \in \mathbb{R}^n.
\]

\( L = (n, n-1, \ldots, 1) \in \mathbb{R}_{>0}^n \) satisfies \( L \cdot V_j = -1 < 0 \). If \( U^-_1 > 0 \) we have existence.

It turns out that \( U^+ \) is unique:

\[
U^+_0 = U^-_0 + \sum_{j=1}^{n-1} \sum_{k=1}^{j} Q_j U^-_k,
\]

\[
U^+_j = 0, \quad i = 1, \ldots, n - 1,
\]

\[
U^+_n = \sum_{i=1}^{n} U^-_i.
\]

Analogously for general stoichiometric coefficients.

(b) Branching reactions.

\[
A_1 \xrightarrow[R_j]{} A_{j+1}, \quad j = 1, \ldots, n - 1.
\]

\[
V_j = (-1, 0, \ldots, 0, 1, 0, \ldots, 0) \in \mathbb{R}^n.
\]

With \( L = (1, 0, \ldots, 0) \), \( L \cdot V_j < 0 \) holds. For \( U^+ \) we get

\[
U^+_0 = U^-_0 + \sum_{j=1}^{n-1} \alpha_j Q_j, \quad U^+_1 = 0,
\]

\[
U^+_i = U^-_i + \alpha_{i-1}, \quad i = 2, \ldots, n,
\]

under the constraint \( \sum_{j=1}^{n-1} \alpha_j = U^-_1 \). Hence \( n - 2 \) of the \( \alpha_j \) are not determined. This is the extreme case of nonuniqueness and typical for branched networks since there exist several reaction paths for reaching equilibrium. Which path actually is observed depends on the initial data of the time depending problem.

(c) Radical reaction.

\[
R_1 : A_1 + A_2 \to A_3 + A_4
\]

\[
A_2 + A_2 \to A_5.
\]
In [3] this describes a simplified global two step mechanism for a hydrocarbon flame, with

\[ A_1 \equiv C_nH_m \quad \text{hydrocarbon} \]
\[ A_2 \equiv O_2 \quad \text{oxygen} \]
\[ A_3 \equiv CO \quad \text{radical} \]
\[ A_4 \equiv H_2O \quad \text{product} \]
\[ A_5 \equiv CO_2 \quad \text{product} \]

For simplicity we assumed the stöchiometric coefficients to be 1.

For \( V_1 = (-1, -1, 1, 1, 0) \) and \( V_2 = (0, -1, -1, 0, 1) \) we may take \( L = (0, 1, 0, 0, 0) \). Let \( U_1^-, U_2^- > 0 \) and \( U_3^- = U_4^- = U_5^- = 0 \). For calculating \( U^+ \) we have to distinguish two cases:

(i) \( 2U_1^- \geq U_2^- \) (fuel rich flames) which gives

\[ U_0^+ = U_0^- + (tQ_1 + (1 - t)Q_2)U_2^- ; \]
\[ U_1^+ = U_1^- - tU_2^-; \quad U_2^+ = 0; \quad U_3^+ = (2t - 1)U_2^- ; \]
\[ U_4^+ = tU_2^-; \quad U_5^+ = (1 - t)U_2^- \]

for some \( t \in [\frac{1}{2}, \min(U_1^- / U_2^- , 1)] \).

(ii) \( 2U_1^- < U_2^- \) (oxygen rich flame) in which case

\[ U_0^+ = U_0^- + (Q_1 + Q_2)U_1^- , \quad U_1^+ = U_3^+ = 0, \]
\[ U_4^+ = U_5^+ = U_2^- , \quad U_2^+ = U_2^- - 2U_1^- . \]

This examples shows that uniqueness of \( U^+ \) depends also on \( U^- \).

4. Concluding remarks. The essential restriction in the existence theorem was that all reactions have to be exothermic. It would be desirable to treat also reversible reactions, for they are present in any realistic combustion process. The effect would be that the final temperature and the flame speed would decrease. This can indeed be proven for a reversible one-step reaction with equal diffusion rates. In general the temperature will not be monotone. But this monotonicity was essentially used in this work. Therefore our method does not apply in this case. Whether there exist travelling waves then depends on the relative magnitude of forward and backward reaction.
