INTERPOLATION OF BESOV SPACES

RONALD A. DEVORE AND VASIL A. POPOV

ABSTRACT. We investigate Besov spaces and their connection with dyadic spline approximation in $L_p(\Omega)$, $0 < p \leq \infty$. Our main results are: the determination of the interpolation spaces between a pair of Besov spaces; an atomic decomposition for functions in a Besov space; the characterization of the class of functions which have certain prescribed degree of approximation by dyadic splines.

1. Introduction. The Besov space $B^a_q(L_p)$ is a set of functions $f$ from $L_p$ which have smoothness $a$. The parameter $q$ gives a finer gradation of smoothness (see (2.4) for a precise definition). These spaces occur naturally in many fields of analysis. Many of their applications require a knowledge of their interpolation properties, i.e. a description of the spaces which arise when the real method of interpolation is applied to a pair of these spaces.

There are two definitions of Besov spaces which are currently in use. One uses Fourier transforms in its definition and the second uses the modulus of smoothness of the function $f$. These two definitions are equivalent only with certain restrictions on the parameters; for example they are different when $p < 1$ and $\alpha$ is small. The first and simplest interpolation theorems for Besov spaces, were for interpolation between a pair $B^\alpha_q(L_p)$ and $B^\beta_p(L_p)$ with $p \geq 1$ fixed. In this case, the real method of interpolation for the parameters $(\theta, s)$ applied to these spaces gives the Besov space $B^{\gamma}_q(L_p)$ with $\gamma = \theta \alpha + (1 - \theta) \beta$. Hence, when $p$ is held fixed the Besov spaces are invariant under interpolation.

More interesting and somewhat more difficult to describe are the interpolation spaces when $p$ is not fixed. Such a program has been carried out in the book of Peetre [P] using the Fourier transform definition of the Besov spaces. The main tool in describing these interpolation spaces is to correspond to each $f$ in the Besov space a sequence of trigonometric polynomials obtained from the Fourier series of $f$. In this way, the Besov space $B^\alpha_q(L_p)$ is identified with a weighted sequence space $l^\alpha_q(L_p)$. Interpolation properties of the Besov spaces are then derived from the interpolation between sequence spaces (when these are known). The success of this approach when $p < 1$ rests on the fact that the corresponding Besov spaces are defined using $H_p$ norms so that each $f$ in the Besov space is a distribution and therefore has a Fourier series.

Key words and phrases. Besov spaces, real interpolation spaces, dyadic splines, degree of approximation.

The first author was supported by NSF Grant DMS 8320562.
The Besov spaces defined by the modulus of smoothness occur more naturally in many areas of analysis including approximation theory. Especially important is the case when $p < 1$ since these spaces are needed in the description of approximation classes for the classical methods of nonlinear approximation such as rational approximation and approximation by splines with free knots (see [Pt and D-P]).

The purpose of the present paper is to describe the interpolation of the Besov spaces defined by the modulus of smoothness. This is established by developing the connections between Besov spaces and approximation by dyadic splines. We shall show that a function is in $B^q_\alpha(L_p)$ if and only if it has a certain rate of approximation by dyadic splines ($\S 4$). In this way, we can identify $B^q_\alpha(L_p)$ with certain sequence spaces in a manner similar to that described above for the Fourier transform definition. While the basic ideas behind such an identification is rather simple, some of the details become technical when dealing with the case $p < 1$. One of the main difficulties encountered is that in contrast to the Fourier transform case, the mapping which we use to associate to each $f \in L_p$ a dyadic spline is nonlinear when $p < 1$.

In the process of proving our interpolation theorem, we shall develop several interesting results about dyadic spline approximation and about the representation of a function $f \in B^q_\alpha(L_p)$ as a series of dyadic splines (see the atomic decomposition in Corollary 5.3).

2. Besov spaces. Let $\Omega$ be the unit cube in $\mathbb{R}^d$. If $f \in L_p(\Omega)$, $0 < p \leq \infty$, we let $\omega_r(f, t)_p$, $t > 0$, denote the modulus of smoothness of order $r$ of $f \in L_p(\Omega)$:

\begin{equation}
\omega_r(f, t)_p := \sup_{|h| \leq t} \| \Delta_h^r(f, \cdot) \|_p(\Omega(rh))
\end{equation}

where $|h|$ is the Euclidean length of the vector $h$; $\Delta_h^r$ is the $r$th order difference with step $h \in \mathbb{R}^d$; and the norm in (2.1) is the $L_p$ "norm" on the set $\Omega(rh) := \{x : x, x + rh \in \Omega\}$. Of course, when $p < 1$, this is not really a norm, it is only a quasi-norm, i.e. in place of the triangle inequality, we have

\begin{equation}
\|f + g\|_p \leq 2^{1/p}[\|f\|_p + \|g\|_p].
\end{equation}

Also useful is the fact that for any $\mu \leq \min(1, p)$ and any sequence $(f_i)$

\begin{equation}
\left\| \sum f_i \right\|_p \leq \left( \sum \|f_i\|_p^\mu \right)^{1/\mu}.
\end{equation}

If $\alpha, p, q > 0$, we say $f$ is in the Besov space $B^q_\alpha(L_p)$ whenever

\begin{equation}
|f|_{B^q_\alpha(L_p)} := \left( \int_0^\infty (t^{-\alpha} \omega_r(f, t)_p)^q \frac{dt}{t} \right)^{1/q}
\end{equation}

is finite. Here, $r$ is any integer larger than $\alpha$. When $q = \infty$, the usual change from integral to sup is made in (2.4).

We also define the following "norm" for $B^q_\alpha(L_p)$:

\begin{equation}
\|f\|_{B^q_\alpha(L_p)} := \|f\|_p + |f|_{B^q_\alpha(L_p)}.
\end{equation}

Different values of $r > \alpha$ result in norms (2.5) which are equivalent. This is proved by establishing inequalities between the moduli of smoothness $\omega_r$ and $\omega_r$. 

License or copyright restrictions may apply to redistribution; see https://www.ams.org/journal-terms-of-use
when $r' \leq r$. A simple inequality is $\omega_r \leq c\omega_{r'}$, which follows readily from (2.2). In the other direction, we have the Marchaud type inequality:

$$\omega_{r'}(f, t)_p \leq ct^{r'} \left[ \|f\|_p + \left( \int_t^\infty (s^{-r'} \omega_r(f, s))^\mu \frac{ds}{s} \right)^{1/\mu} \right]$$

which holds for every $\mu \leq \min(1, p)$. This inequality can be proved by using standard identities for differences. In §4, we give a different proof of (2.6) using dyadic spline approximation. Using these two inequalities for moduli together with the Hardy inequality [B-B, p. 199], one shows that any two norms (2.5) are equivalent provided that $r > \alpha$.

There are many other norms which are equivalent to (2.5). We shall have occasion to use several of these which we describe in later sections. A simple observation is

$$\|f\|_{B^q_p(I_p)} \simeq \|f\|_p + \left( \sum_{k=1}^\infty 2^{k\alpha} \omega_r(f, 2^{-k})_p^q \right)^{1/q}.$$

In fact, since $\omega_r$ is bounded, the integral in (2.4) is equivalent to the integral of the same integrand taken over $[0, 1]$. Now, the monotonicity properties of $\omega_r$ allow us to discretize the integral and obtain that (2.7) is equivalent to (2.4).

### 3. Local polynomial approximation.

We want to show that $\omega_r(f, 2^{-k})_p$ in (2.7) can be replaced by the error of dyadic spline approximation. This requires inequalities between the modulus of smoothness and the degree of spline approximation. These will be given in §4. To estimate the degree of spline approximation by the modulus of smoothness, we first need estimates for local polynomial approximation. We define the local error of approximation by polynomials by

$$E_r(f, I)_p := \inf_{\deg(Q) \leq r} \|f - Q\|_p(I).$$

with $\deg(Q)$ the coordinate degree of $Q$. We use the notation $\|\|_p(I)$ to denote the $L_p$ norm over $I$; when $I$ is omitted the norm is understood to be taken over $\Omega$.

We shall need an estimate for the local error of polynomial approximation in terms of the smoothness of $f$. One such estimate is Whitney’s theorem:

$$E_r(f, I)_p \leq c\omega_r(f, l_I)_p$$

with $l_I$ the side length of $I$. Here and in what follows, $c$ is a constant which depends only on $r, d$ (and $p$, if $p$ appears) unless otherwise stated. The value of $c$ may vary at each appearance.

Whitney’s theorem is best known for univariate functions and $p \geq 1$. It has also been proved by Yu. Brudnyi [Br] for multivariate functions and $p \geq 1$. A proof of (3.2) for all $p$ and all dimensions $d$ can be found in the paper of Storozhenko and Oswald [S-O]. We would also like to mention that the ideas used in the univariate proof for $p \geq 1$ carry over to the general case. For example, in the forthcoming book of Popov and Petrushev [P-P], the reader will find a proof of this type for $p < 1$ for univariate functions.
The modulus of smoothness is not suitable when we want to add up estimates over several intervals. We therefore introduce the following modified modulus:

\[
(3.3) \quad \omega_r(f, t) p := \omega_r(f, t, I) p := \left( t^{-d} \int_{\Omega_t} \int_{I(r,s)} |\Delta^s(f, x)|^p dx \, ds \right)^{1/p}, 
\]

where \( \Omega_t := [-t, t]^d \). Using identities for differences, it can be shown that \( \omega_r \) and \( \omega_r^* \) are equivalent, i.e., \( c_1 \omega_r(f, t) p \leq \omega_r^*(f, t) p \leq c_2 \omega_r(f, t) p \), with constants \( c_1, c_2 > 0 \) which depend only on \( r, p \) and \( d \) (see [P-P] for a proof of this in the univariate case; the same proof applies to the multivariate case as well). From this, we have the following result.

**Lemma 3.1.** If \( f \in L^p(I) \), with \( 0 < p \leq \infty \) and if \( I \) is a cube with side length \( l_I \), then

\[
(3.4) \quad E_r(f, I) p \leq c \omega_r(f, l_I, I) p. 
\]

This result in a slightly different form can also be found in [S-O].

There always exist polynomials \( Q \) of best \( L^p(I) \) approximation of coordinate degree \( < r \): \( \| f - Q \| p(I) = E_r(f, I) p \). In the present paper we shall also find it very useful to use the concept of “near best” approximation. We say \( Q \) is a near best \( L^p(I) \) approximation to \( f \) from polynomials of coordinate degree \( < r \) with constant \( A \) if

\[
(3.5) \quad \| f - Q \| p(I) \leq A E_r(f, I) p. 
\]

It follows that if \( P \) is any polynomial of coordinate degree \( < r \), then

\[
(3.6) \quad \| f - Q \| p(I) \leq A \| f - P \| p(I). 
\]

One method for constructing near best approximants of \( f \) is as follows. We let \( \rho \leq p \) and we let \( Q_\rho \) be any polynomial of near best \( L^p(I) \) approximation to \( f \) of coordinate degree \( < r \), i.e. \( \| f - Q_\rho \| \rho(I) \leq A E_r(f, I) \rho \).

**Lemma 3.2.** If \( \rho \leq p \), and \( Q_\rho \) is as above, we have

\[
(3.7) \quad \| f - Q_\rho \| p(I) \leq c A E_r(f, I) p 
\]

with the constant \( c \) depending only on \( r, d \) and \( \rho \).

**Proof.** Let \( Q \) be a best \( L^p(I) \) approximation to \( f \) of coordinate degree \( < r \). Then, from elementary properties of polynomials (see [D-Sh, §3], we have with \( \theta := 1/p - 1/\rho \),

\[
\| f - Q_\rho \| p \leq c(E_r(f, I) p + \| Q - Q_\rho \| p) 
\leq c(E_r(f, I) p + |I|^\theta \| Q - Q_\rho \| p) 
\leq c(E_r(f, I) p + |I|^\theta (\| f - Q_\rho \| p(I) + \| f - Q_\rho \| \rho(I))) 
\leq c(E_r(f, I) p + |I|^\theta (A + 1) \| f - Q_\rho \| p(I)) 
\leq c(E_r(f, I) p + (A + 1) \| f - Q_\rho \| p(I)) \leq c A E_r(f, I) p.
\]

Here, the first inequality uses the quasi-norm property (2.2); the second inequality is a comparison of polynomial norms; the third again uses (2.2); the fourth uses (3.6); and the fifth inequality is Hölder’s inequality.
We introduce the following notation. If \( I \) is any cube, we let \( P_I \) denote any near best \( L_p(I) \) approximation to \( f \) from polynomials of coordinate degree \( < r \) with constant \( A \). The following lemma shows that \( P_I \) is also a near best approximation on larger cubes.

**Lemma 3.3.** For any \( p \geq \rho \) and any cube \( J \supseteq I \) with \( |J| \leq a|I| \), we have

\[
\|f - P_I\|_p(J) \leq cE_r(f, J)_p,
\]

with \( c \) depending at most on \( r, d, a \) and \( A \).

**Proof.** If \( P \) is the best \( L_p \) approximation to \( f \) on \( J \) from polynomials of coordinate degree \( < r \), then from (2.2) and Lemma 3.2,

\[
\|P_I - P\|_p(I) \leq c[\|f - P\|_p(I) + \|f - P\|_p(I)]
\leq c[E_r(f, I)_p + E_r(f, J)_p]
\leq cE_r(f, J)_p.
\]

This estimate can be enlarged to \( J \) (see \([D-Sh, \S 3]\)):

\[
\|P_I - P\|_p(J) \leq cE_r(f, J)_p.
\]

Hence,

\[
\|f - P_I\|_p(J) \leq c[\|f - P\|_p(J) + \|P - P_I\|_p(J)] \leq cE_r(f, J).
\]

\( \square \)

4. **Dyadic spline approximation.** We want in this section to describe the connection between Besov spaces and dyadic spline approximation. Our main goal is to show that \( \omega_r \) in (2.6) can be replaced by an error in dyadic spline approximation with a resulting equivalent seminorm. This means that the Besov spaces \( B^\alpha_q(L_p) \) are the approximation spaces for the approximation by dyadic splines in \( L_p \). Such characterizations are known when \( p \geq 1 \) (see \([C]\); also \([D-S]\)) and when \( p < 1 \) and \( d = 1 \) (see \([O]\)).

We let \( D_k \) denote the collection of dyadic cubes of \( \mathbb{R}^d \) of side length \( 2^{-k} \) and we let \( D_k(\Omega) \) denote the set of those cubes \( I \in D_k \) with \( I \subseteq \Omega \). We introduce two spline spaces for this partition. The first of these is \( \Pi_k := \Pi_k(r) \), the space of all piecewise polynomials of coordinate degree \( < r \) on the partition \( D_k \). That is, \( S \in \Pi_k \) means that in the interior of each cube \( I \in D_k \), \( S \) is a polynomial of coordinate degree \( < r \). We denote by \( \Pi_k(\Omega) \) the restrictions of splines \( S \) in \( \Pi_k \) to \( \Omega \).

A best (or near best) approximation \( S_k \) to \( f \) in \( L_p(\Omega) \) from \( \Pi_k(\Omega) \) is gotten by simply taking \( S := P_I \), \( x \in I \), where \( P_I \), \( I \in D_k(\Omega) \), is a best (or near best) approximation to \( f \) in \( L_p(I) \) by polynomials of coordinate degree \( < r \) on each cube \( I \) from \( D_k(\Omega) \). However, we shall also need to construct good approximations from \( \Pi_k(\Omega) \) which have smoothness. For this, we shall use the tensor product \( B \)-splines and the quasi-interpolants of de Boor-Fix.

Let \( N \) be the univariate \( B \)-spline of degree \( r - 1 \) which has knots at the points \( 0, 1, \ldots, r \), i.e., \( N(x) := r[0, 1, \ldots, r](x - \cdot)_{r-1}^{-1} \) with the usual divided difference notation. For higher dimensions, we define \( N \) by

\[
N(x) := N(x_1) \cdots N(x_d).
\]

These are the tensor product \( B \)-splines. They are piecewise polynomials of coordinate degree \( < r \) which have continuous derivatives \( D^\nu N, 0 \leq \nu \leq r - 2 \), and
derivatives $D^\nu N$ in $L_\infty$ for $0 \leq \nu < r - 1$. We use the notation $k := (k, k, \ldots, k)$. The splines $N$ are nonnegative and are supported on the cube $[0, r]^d$.

To get splines in the space $\Pi_k$, we let

$$(4.2) \quad N_k(x) := N(2^k x), \quad k = 0, 1, \ldots,$$

and

$$(4.3) \quad N_{j,k}(x) := N_k(x - x_j), \quad j \in \mathbb{Z}^d,$$

where the $x_j := 2^{-k}j$ are the vertices of the cubes in $D_k$. The $B$-splines $N_{j,k}$ are a partition of unity, i.e.

$$\sum_{j \in \mathbb{Z}^d} N_{j,k} \equiv 1, \text{ on } \mathbb{R}^d.$$

Each spline $S$ in the span of the $N_{j,k}$ can be written in a $B$-spline series:

$$(4.5) \quad S = \sum_{j \in \mathbb{Z}^d} \alpha_j(S) N_{j,k}$$

with the $\alpha_j := \alpha_{j,k}$ the dual functionals of the $N_{j,k}$. The functionals $\alpha_j$ can be expressed in terms of the univariate functionals:

$$(4.6) \quad \alpha_j(S) = \alpha_{j,1}(\cdots \alpha_{j,d}(S)))$$

where the univariate functional $\alpha_{j,\nu}$ is applied to a multivariate function $g$ by considering $g$ as a function of $x_\nu$ with the other variables held fixed.

There are many representations for the functionals $\alpha_j$. We mention in particular, the de Boor-Fix formula [B-F]. This representation gives that for any point $\xi_j$ in the supp($N_j$), we can write

$$(4.7) \quad \alpha_j(S) = \sum_{0 \leq \nu \leq r-1} a_\nu D^\nu(S)(\xi_j), \quad j \in \Lambda,$$

for certain coefficients $a_\nu$ depending on $\xi_j$ and $r$.

For approximation on $\Omega$, we need only the $B$-splines $N_{j,k}$ which do not vanish identically on $\Omega$. We let $\Lambda := \Lambda(k)$ denote the set of $j$ for which this is the case and we let $\Sigma_k := \Sigma_k(\Omega)$ denote the linear span of the $B$-splines $N_{j,k}, j \in \Lambda$. Then any $S \in \Sigma_k$ can be written

$$(4.8) \quad S = \sum_{j \in \Lambda} \alpha_j(S) N_{j,k}.$$

For the representation of $\alpha_j, j \in \Lambda$, we shall choose the points $\xi_j$ as the center of a cube $J_j := J_{j,k} \in D_k$ such that

$$(4.9) \quad \xi_j \in J_j \subset \text{supp}(N_j) \cap \Omega, \quad j \in \Lambda.$$

With this choice, we can define $\alpha_j(f)$ for any $f$ which is suitably differentiable at $\xi_j$. In particular, in this way, we have that $\alpha_j$ is defined for any $S$ in $\Pi_k$.

From (4.7), it is easy to estimate the coefficients of a spline $S \in \Pi_k$. 

License or copyright restrictions may apply to redistribution; see https://www.ams.org/journal-terms-of-use
LEMMA 4.1. We have for any $0 < p \leq \infty$ and any $S \in \Pi_k$,

\begin{equation}
|\alpha_j(S)| \leq c_2 k^{d/p} \|S\|_p(J_j).
\end{equation}

PROOF. This is well known for one variable and $p \geq 1$. A similar proof applies in the general case. For example, from Markov’s inequality applied to $S$ on $J_j$ and estimates for the coefficients $a_{\nu}$ (see [D]), it follows that

\begin{equation}
|\alpha_j(S)| \leq c \|S\|_\infty(J_j).
\end{equation}

Since $|J_j| = 2^{-kd}$, (4.10) follows from (4.11) and the well-known inequality between $L_p$ and $L_\infty$ norms for polynomials (see e.g. [D-Sh, §3]). \qed

Closely related to (4.10) is the following.

LEMMA 4.2. If $S = \sum_{j \in A} \alpha_j N_{j,k}$ is in $\Sigma_k$, then for any $0 < p \leq \infty$, we have

\begin{equation}
c_1 \|S\|_p \leq \left( \sum_{j \in A} |\alpha_j(S)|^p 2^{-kd} \right)^{1/p} \leq c_2 \|S\|_p
\end{equation}

with $c_1, c_2$ depending at most on $d$ and $r$.

PROOF. Again this is well known (see [B]) when $p \geq 1$ and the general case is proved in the same manner. For example, since $\Sigma_k \subset \Pi_k$, the right side of (4.12) follows from (4.10) and the fact that a point $x$ falls in at most $r^d$ of the cubes $J_j$. For the left inequality, we use the fact that at most $r^d$ terms in the representation of $S$ are nonzero at a given point $x$. Hence

$$|S(x)|^p \leq c \sum_{j \in A} |\alpha_j|^p N_{j,k}(x)^p.$$ Integrating with respect to $x$ and using the fact that the integral of $N_{j,k}^p$ is less than $c 2^{-kd}$ (because $N_{j,k} \leq 1$) gives the desired result. \qed

Now, let $f$ be any function which is $r - 1$ times continuously differentiable at each of the points $\xi_j$. Then $\alpha_j(f)$ is defined for all $j$ and we define

\begin{equation}
Q_k(f) := \sum_{j \in A} \alpha_j(f) N_{j,k}.
\end{equation}

The $Q_k$ are called quasi-interpolant operators. In particular $Q_k$ is defined for all $S \in \Pi_k$, and it follows that $Q_k$ is a projector from $\Pi_k$ onto $\Sigma_k$: $Q_k(S) = S$ whenever $S \in \Sigma_k$.

We want to examine the approximation properties of the $Q_k$. For this, we introduce the following notation. If $I \in D_k$, we let $\tilde{I}$ be the smallest cube which contains each of the $J_j$ for which $\text{supp} \ N_{j,k} \cap I \neq \emptyset$. Then, $\tilde{I} \subset \Omega$ and $|\tilde{I}| \leq c|I|$ with $c$ depending only on $d$ and $r$.

LEMMA 4.3. If $S \in \Pi_k$ and $0 < p \leq \infty$, then for each $I \in D_k(\Omega)$, we have

\begin{equation}
\|Q_k(S)\|_p(I) \leq c \|S\|_p(\tilde{I}),
\end{equation}

and

\begin{equation}
\|S - Q_k(S)\|_p(I) \leq c E_r(S, \tilde{I})_p.
\end{equation}
PROOF. We let $A_I$ be the set of $j$ such that $N_{j,k}$ does not vanish identically on $I$. We use the representation (4.13) and the estimate (4.10) for the functionals $\alpha_j$, to find

$$\|Q_k(S)\|_p(I) \leq \max_{j \in A_I} |\alpha_j(S)| \left\| \sum_{j \in A_I} N_{j,k} \right\|_p(I) \leq c|I|^{1/p} \max_{j \in A_I} 2^{kd/p} \|S\|_p(J_j) \leq c\|S\|_p(\tilde{I}),$$

because of (4.4). This is (4.14).

To prove (4.15), we let $I \in D_k$ and let $P$ be a polynomial of best $L_p(\tilde{I})$ approximation to $S$ of coordinate degree $< r$. Since $Q_k(P) = P$, we have by (2.2) and (4.14),

$$\|S - Q_k(S)\|_p(I) \leq c[\|S - P\|_p(I) + \|Q_k(S - P)\|_p(I)] \leq c\|S - P\|_p(\tilde{I}) = cE_r(S, \tilde{I}).$$

COROLLARY 4.4. If $0 < p \leq \infty$, then $\|Q_k(S)\|_p \leq c\|S\|_p$ for all $S \in \Sigma_k$.

PROOF. This follows immediately from (4.14) when $p = \infty$. When $0 < p < \infty$, we raise both sides of (4.14) to the power $p$ and then we sum over $I \in D_k(\tilde{\Omega})$. Since each point $x \in \Omega$ appears in at most $c$ of the cubes $\tilde{I}$, with $c$ depending only on $r$ and $d$, the corollary follows. □

We want to describe a class of methods for approximating each $f$ in $L_p(\tilde{\Omega})$ by smooth dyadic splines from $\Sigma_k$. For each $I \in D_k$ and $f \in L_p(\tilde{\Omega})$, we let $P_I := P_I(f)$ be a near best $L_p(I)$ approximation to $f$ from polynomials of coordinate degree $< r$ with an absolute constant $A$. We then define $S_k := S_k(f) \in \Pi_k$, $k = 0, 1, \ldots$, to be the piecewise polynomial

$$S_k := P_I(x), \quad x \in \text{interior}(I), \quad \text{for all } I \in D_k.$$

From (3.8), we have

$$\|f - P_I\|_p(\tilde{I}) \leq cE_r(f, \tilde{I}), \quad I \in D_k,$$

with $c$ depending only on $r, d$ and $A$.

Going further, for each $f \in L_p(\tilde{\Omega})$, we define

$$T_k := T_k(f) := Q_k(S_k(f)), \quad k = 0, 1, \ldots.$$

Then $T_k$ is in $\Sigma_k$ and we have

$$\|T_k(f)\|_p \leq c\|f\|_p$$

with $c$ depending only on $r, d$ and $A$. Indeed, since $P_I$ is a near best approximation to $f$, we have $\|P_I\|_p(I) \leq c\|f\|_p(I)$, $I \in D_k(\tilde{\Omega})$. Hence, $\|S_k(f)\|_p \leq c\|f\|_p$ and therefore (4.21) follows from Corollary 4.4.

THEOREM 4.5. For any of the operators $T_k$ in (4.20) and for each $f \in L_p(\tilde{\Omega})$, we have

$$\|f - T_k(f)\|_p \leq c\omega_r(f, 2^{-k})_p, \quad k = 0, 1, \ldots,$$

with $c$ depending only on $r, d, p$ and $A$. 

License or copyright restrictions may apply to redistribution; see https://www.ams.org/journal-terms-of-use
PROOF. From (4.15), we have for each $I \in D_k(\Omega)$,
\begin{align}
\|f - T_k\|_p(I) &\leq c \|f - S_k\|_p(I) + \|S_k - Q_k(S_k)\|_p(I) \\
&\leq c \|f - P_f\|_p(I) + E_r(S_k, \tilde{I})_p \\
&\leq c [E_r(f, \tilde{I})_p + E_r(S_k, \tilde{I})_p].
\end{align}

Now, for any cube $J \subseteq \tilde{I}$ with $J \in D_k$, we have from (4.19)
\begin{align}
\|S_k - P_f\|_p(J) = \|P_f - P_f\|_p(J) &\leq c \|f - P_f\|_p(J) + \|f - P_f\|_p(J) \\
&\leq c [E_r(f, J)_p + E_r(f, \tilde{I})_p] \\
&\leq c E_r(f, I)_p.
\end{align}

Since the number of cubes $J \in D_k$ contained in $\tilde{I}$ depends only on $d$ and $r$, (4.24) gives $E_r(S_k, \tilde{I})_p \leq c E_r(f, \tilde{I})_p$. If we use this in (4.23), we obtain
\begin{align}
\|f - T_k\|_p(I) &\leq c E_r(f, I)_p.
\end{align}

Now, each point $x \in \Omega$ appears in only a constant depending only on $r$ and $d$ number of cubes $\tilde{I}$. Hence, if we raise both sides of (4.25) to the power $p$ and sum over all $I$ in $D_k(\Omega)$ and use (3.4), we obtain
\begin{align}
\|f - T_k\|_p^p(\Omega) &\leq c \sum_{I \in D_k(\Omega)} w_r(f, I, \tilde{I})^p \\
&\leq c t^{-d} \int_{\Omega} \int_{\Omega(r_2)} |\Delta^L_s(f, x)|^p \, dx \, ds
\end{align}

with $t := \max I \leq c 2^{-k}$. Here, we have used the fact that $w_r(f, t')_p \leq c w_r(f, t)_p$ provided $t' \leq t \leq ct'$. Finally, (4.22) follows from (4.26) because each of the interior integrals on the right side of (4.26) does not exceed $\omega_r(f, t)_p^p$ which from the usual properties of moduli is $\leq c \omega_r(f, 2^{-k})_p^p$. \hfill \Box

Theorem 4.5 shows that the error of dyadic approximation can be majorized by the modulus of smoothness. Namely, if we let
\begin{align}
s_k(f)_p &:= \inf_{S \in \Sigma_k} \|f - S\|_p,
\end{align}
then we have

**COROLLARY 4.6.** For each $f \in L_p(\Omega)$, and for each $r = 1, 2, \ldots$, we have
\begin{align}
s_k(f)_p &\leq c \omega_r(f, 2^{-k})_p, \quad k = 0, 1, \ldots.
\end{align}

It is also important to note that $T_k(f)$ is a near best approximation from $\Sigma_k$.

**COROLLARY 4.7.** If $f \in L_p(\Omega)$, then
\begin{align}
\|f - T_k(f)\|_p &\leq c s_k(f)_p
\end{align}

with $c$ depending only on $r, d, p$ and $A$.

**PROOF.** Let $S$ be a best $L_p(\Omega)$ approximation to $f$ from $\Sigma_k$. Then since $Q_k(S) = S$, we have $f - T_k(f) = f - S + Q_k(S - S_k(f))$. If we use the fact that $Q_k$ is bounded (Corollary 4.4), we obtain
\begin{align}
\|f - T_k(f)\|_p &\leq c \|f - S\|_p + \|S - S_k(f)\|_p \\
&\leq c \|f - S\|_p + \|f - S_k(f)\|_p \leq c s_k(f)_p.
\end{align}
Here, the last inequality uses the fact that $S_k(f)$ is a near best approximation from $\Pi_k$ with constant $A$ and the error of approximating $f$ from $\Pi_k$ is smaller than the error in approximating $f$ from $\Sigma_k$ (because $\Sigma_k \subset \Pi_k$).

We also need inverse estimates to (4.28). We let $s_{-1}^r(f)_p := \|f\|_p$.

**Theorem 4.8.** For each $k > 0$, and each $r = 1, 2, \ldots$, we have for $\lambda := \min(r, r - 1 + 1/p)$ and for each $f \in L_p$,

\[
(4.29) \quad \omega_r(f, 2^{-k})_p \leq c 2^{-k\lambda} \left( \sum_{j=-1}^{k} [2^j s_j(f)_p]^\mu \right)^{1/\mu},
\]

provided $\mu \leq \min(1, p)$.

**Proof.** We let $U_k$ be a best approximation to $f$ from $\Sigma_k$ and let $u_k := U_k - U_{k-1}$, $k = 0, 1, \ldots$, with $U_{-1} := 0$. If $|h| < r^{-1} 2^{-k}$ and $x \in \Omega(rh)$, we write

\[
(4.30) \quad \Delta^r_h(f, x) = \Delta^r_h(f - U_k, x) + \sum_{j=0}^{k} \Delta^r_h(u_j, x).
\]

Then, from (2.3),

\[
(4.31) \quad \|\Delta^r_h(f)\|_p(\Omega(rh)) \leq c \left( s_k(f)_p + \sum_{j=0}^{k} \|\Delta^r_h(u_j)\|_p(\Omega(rh)) \right)^{1/\mu}.
\]

To estimate $\|\Delta^r_h(u_j)\|_p(\Omega(rh))$, we write $u_j$ in its $B$-spline series:

\[
(4.32) \quad u_j = \sum_{\nu \in \Lambda(j)} \alpha_{\nu,j}(u_j) N_{\nu,j}.
\]

For any $x$, at most $c$ $B$-splines (4.32) are nonzero at $x$ with $c$ depending only on $r$ and $d$. Hence,

\[
(4.33) \quad |\Delta^r_h(u_j, x)|^p \leq c \sum_{\nu \in \Lambda(j)} |\alpha_{\nu,j}(u_j)|^p |\Delta^r_h(N_{\nu,j}, x)|^p.
\]

Now, we shall give two estimates for $\Delta^r_h(N_{\nu,j}, x)$. The first of these is for the set $\Gamma$ which consists of all $x$ such that $x$ and $x + rh$ are in the same cube $I \in D_j$ and $N_{\nu,j}$ does not vanish identically on $I$. Since $N_{\nu,j}$ is a polynomial on $I$ whose $r$th order derivatives do not exceed $c2^j r$, we have

\[
(4.34) \quad |\Delta^r_h(N_{\nu,j}, x)| \leq c (2^j |h|)^r, \quad x \in \Gamma.
\]

Our second estimate is for the set $\Gamma'$ which consists of all $x$ such that $x$ and $x + rh$ are in different cubes from $D_j$ and $N_{\nu,j}$ does not vanish identically on both of these cubes. Since $N_{\nu,j} \in W^{r-1}_\infty$ (Sobolev space) has $(r-1)$th derivatives whose $L_\infty$ norms do not exceed $c2^j (r-1)$, we have

\[
(4.35) \quad |\Delta^r_h(N_{\nu,j}, x)| \leq c (2^j |h|)^{r-1}, \quad x \in \Gamma'.
\]

Now, the set $\Gamma$ has measure $\leq c2^{-jd}$ because the support of $N_{\nu,j}$ has measure $\leq c2^{-jd}$. Also, $\Gamma'$ has measure $\leq c|h|2^{-j(d-1)}$. Indeed, for $x$ to be in $\Gamma'$, we must have $\text{dist}(x, \text{bound}(I)) \leq \tau|h|$ for the cube $I$ which contains $x$. The measure of all
such \( x \in I \) is less than \( c|h|2^{-j(d-1)} \). Since \( N_{\nu,j} \) vanishes on all but \( c \) cubes with \( c \) depending only on \( r \) and \( d \), we have \( |\Gamma'| \leq c|h|2^{-j(d-1)} \) as claimed.

Using these two estimates for the measure of \( \Gamma \) and \( \Gamma' \) together with (4.34) and (4.35), we obtain

\[
(4.36) \quad \int_{\Omega(rh)} |\Delta^j_h(N_{\nu,j})|^p \leq c|h|^{\lambda p} 2^{j\lambda p} |2^{-j(d-1)}| \leq c|h|^{\lambda p} 2^{j\lambda p} 2^{-jd}
\]

because \( |h|2^{-k} \leq r^{-1} \leq 1 \).

Now, we integrate (4.33) and use (4.36) to find

\[
(4.37) \quad \|\Delta^j_h(u_j)\|_p \leq c|h|^{\lambda 2^j\lambda} \left( \sum \left| \alpha_{\nu,j}(u_j) \right|^{p} 2^{-jd} \right)^{1/p} \leq c|h|^{\lambda 2^j\lambda} \|u_j\|_p \leq c|h|^{\lambda 2^j\lambda} [s_j(f)_p + s_{j-1}(f)_p],
\]

where the next to last inequality is (4.12) and the last inequality is the triangle inequality applied to \( u_j = f - U_{j-1} - (f - U_j) \).

If we use (4.37) in (4.31), we obtain

\[
(4.38) \quad \|\Delta^j_h(f)\|_p(\Omega(rh)) \leq c \left( s_k(f)^\mu + |h|^{\mu \lambda} \sum _{j=-1}^{k} [2^j s_j(f)]^\mu \right)^{1/\mu}.
\]

If we now take a sup over all \( |h| \leq r^{-1}2^{-k} \), (4.38) gives

\[
\omega_r(f,2^{-k})_p \leq c\omega_r(f, r^{-1}2^{-k})_p \leq c2^{-k\lambda} \left( 2^{k\lambda \mu} s_k(f)_\mu + \sum _{j=-1}^{k} [2^j s_j(f)]^\mu \right)^{1/\mu}.
\]

Since the term \( 2^{k\lambda \mu} s_k(f)_\mu \) can be incorporated into the sum, we obtain (4.29). □

It is also possible to estimate \( \omega_{r'} \) for each \( r' < r \):

\[
(4.39) \quad \omega_{r'}(f,2^{-k})_p \leq c2^{-kr'} \left( \sum _{j=-1}^{k} (2^{j r'} s_j(f)_p)^\mu \right)^{1/\mu}.
\]

Indeed, this is proved in exactly the same way as we have derived (4.29), except that, in place of (4.34) and (4.35), we use the inequality

\[
(4.40) \quad |\Delta^j_h(N_{\nu,j},x)| \leq c|h|^{\lambda 2^j \lambda'}
\]

which follows from the fact that \( N_{\nu,j} \) has all derivatives of order \( r' \) in \( L_\infty \).

With (4.39), we can easily prove the Marchaud type inequality (2.6).

COROLLARY 4.9. There is a constant \( c \) depending only on \( p, r, \) and \( d \) such that for each \( f \in L_p, \) we have the inequality

\[
\omega_r(f,2^{-k})_p \leq c \omega_r(f,2^{-1})_p \leq 2^{-k\lambda} \left( \sum _{j=0}^{k} (2^{j r} \omega_r(f,2^{-j})_p)^\mu \right)^{1/\mu}
\]

and (2.6) then follows from the monotonicity of \( \omega_r \). □
5. Other seminorms for Besov spaces. The estimates of the last section allow us to introduce several norms which are equivalent to $\|f\|_{B^s_q(L_p)}$. If $a := (a_k)$ is a sequence whose component functions are in the quasi-normed space $X$, we use the $l_q^s(X)$ “norms”

$$\|a\|_{l_q^s(X)} := \left( \sum_{k=0}^{\infty} 2^{kq} |a_k|_X \right)^{1/q}$$

with the usual change to a supremum norm when $q = \infty$. When $(a_k)$ is a sequence of real numbers, we replace $\|a_k\|_X$ by $|a_k|$ in (5.1) and denote the resulting norm by $\|(a_k)\|_{l_q^s}$.

Useful for us will be the discrete Hardy inequalities

$$\| (b_k) \|_{l_q^s} \leq c \| (a_k) \|_{l_q^s}$$

which hold if either

(i) $|b_k| \leq c 2^{-k\lambda} \left( \sum_{j=0}^{k} |2^j a_j| \right)^{1/\mu}$

(ii) $|b_k| \leq c \left( \sum_{j=k}^{\infty} |a_j| \right)^{1/\mu}$

with $\mu \leq q$ and (in (i)) $\alpha < \lambda$. Here, the constant $c$ in (5.2) depends only on $r, d$ and $1/(\lambda - \alpha)$ in case of (i) and $1/\alpha$, in the case of (ii).

In the following theorem, we let $T_k := T_k(f)$ be defined as in (4.20) for a given $r = 1, 2, \ldots$ and given near best approximations $P_l$ with constant $A$. We let $t_k := t_k(f) := T_k - T_{k-1}$ with $T_{-1} := 0$ and let $\lambda := \min(r - 1 + 1/p, r)$, as before.

**Theorem 5.1.** Let $0 < \alpha$ and $0 < q, p \leq \infty$. If $\alpha < \lambda$, then the following norms are equivalent to $N(f) := \|f\|_{B^s_q(L_p)}$ with constants of equivalency depending only on $d, r$ and $A$ and the constant of (5.2):

(i) $N_1(f) := \|(s_k(f))\|_{l_q^s} + \|f\|_p$

(ii) $N_2(f) := \|(f - T_k(f))\|_{l_q^s(L_p)} + \|f\|_p$

(iii) $N_3(f) := \|(t_k(f))\|_{l_q^s(L_p)}$

**Proof.** From Theorem 4.5, $s_k(f)_p \leq \|f - T_k(f)\|_p \leq c \omega_r(2^{k})_p$. Hence, $N_1(f) \leq N_2(f) \leq cN(f)$. On the other hand, from Theorem 4.8 and the Hardy inequality (5.2) above, we have $N(f) \leq c N_1(f)$. This shows that $N(f)$, $N_1(f)$ and $N_2(f)$ are all equivalent. Since $\|t_k\|_p \leq c [\|f - T_k\|_p + \|f - T_{k-1}\|_p]$ we have $N_3(f) \leq c N_2(f)$. In the other direction $f - T_k = \sum_{j=k+1}^{\infty} t_j$ and therefore from (2.3), we obtain for $k = -1, 0, 1, \ldots$,

$$\|f - T_k\|_p \leq \left( \sum_{k+1}^{\infty} \|t_j\|_p^\mu \right)^{1/\mu}.$$

Note, when $k = -1$, this is an estimate for $\|f\|_p$. Now, from the Hardy inequality (5.2), we have $N_2(f) \leq c N_3(f)$ and therefore $N_2(f)$ and $N_3(f)$ are equivalent.
The norm $N_1$ of Theorem 5.1 shows that a function $f$ is in $B^\alpha_q(L_p)$ if and only if $(s_k(f))$ is in $l^\alpha_q$. In the terminology of [D-P], we have that the approximation class $A^\alpha_q$ for dyadic spline approximation in $L_p$ is the same as the Besov space $B^\alpha_q(L_p)$. Related to this is the following Bernstein type inequality for dyadic splines.

**Corollary 5.2.** If $r = 1, 2, \ldots$ and $\alpha < \lambda$, then for each $S \in \Sigma_n$,

$$\|S\|_{B^\alpha_q(L_p)} \leq c 2^{\alpha n} \|S\|_p$$

with $c$ independent of $S$ and $n$.

**Proof.** Since $S \in \Sigma_n$, $s_k(S) = 0$, $k \geq n$, and for $k < n$, we have $s_k(S)_p \leq \|S\|_p$. Hence, for $q < \infty$,

$$N_1(S)^q \leq c \sum_{k=-1}^{n} |2^{k\alpha} s_k(S)|^q \leq c 2^{\alpha n q} \|S\|^q_p$$

and (5.5) follows from Theorem 5.1. Similarly for $q = \infty$. \qed

Another interesting application of Theorem 5.1 is the following atomic decomposition for functions $f$ in $B^\alpha_q(L_p)$. According to Theorem 5.1, we can write $f = \sum t_k$ with the notation of that theorem. Since $t_k \in \Sigma_k$, we have

$$t_k = \sum_{\nu \in \Lambda(k)} \alpha_{\nu,k} N_{\nu,k}$$

with $N_{\nu,k}$ the $B$-splines for $D_k$. Hence,

$$f = \sum_{k=0}^{\infty} \sum_{\nu \in \Lambda(k)} \alpha_{\nu,k} N_{\nu,k}$$

with convergence in the sense of $L_p$.

**Corollary 5.3.** Let $0 < q, p \leq \infty$ and $r = 1, 2, \ldots$. If $0 < \alpha < \lambda$, then a function $f \in L_p$ is in $B^\alpha_q(L_p)$ if and only if $f$ can be represented as in (5.7) with

$$N_4(f) := \left( \sum_{k=0}^{\infty} 2^{kq} \left( \sum_{\nu \in \Lambda(k)} |\alpha_{\nu,k}|^{p 2^{-kd}} \right)^{q/p} \right)^{1/q} < \infty$$

(and the usual modification if either $p$ or $q = \infty$) and $N_4(f)$ is equivalent to $\|f\|_{B^\alpha_q(L_p)}$.

**Proof.** From Lemma 4.2,

$$\|t_k\|_p \simeq \left( \sum_{\nu \in \Lambda(k)} |\alpha_{\nu,k}|^p \right)^{1/p} .$$

Hence from Theorem 5.1, $N_4(f)$ is equivalent to $N_3(f)$ which is in turn equivalent to $N(f)$. \qed

A different atomic decomposition was given by M. Frazier and B. Jaewerth [F-J] for Besov spaces defined by the Fourier transform. In the case $d = 1$, there is also an atomic decomposition using spline functions by Ciesielski [C].
6. Interpolation theorems. We are now interested in proving interpolation theorems for Besov spaces. If \( \alpha_0, \alpha_1 > 0 \), and \( 0 < p_0, p_1, q_0, q_1 \leq \infty \), we introduce the abbreviated notation \( B_i := B_{q_i}^{p_i}(L_{p_i}) \) and \( l_i := l_{q_i}^{p_i}(L_{p_i}) \), \( i = 0, 1 \).

We recall that if \( X_0, X_1 \) is a pair of quasi-normed spaces which are continuously embedded in a Hausdorff space \( X \), then the \( K \)-functional
\[
K(f, t, X_0, X_1) := \inf_{f = f_0 + f_1} \{ \| f_0 \|_{X_0} + t \| f_1 \|_{X_1} \}
\]
is defined for all \( f \in X_0 + X_1 \). This \( K \)-functional determines new function spaces. If \( 0 < \theta < 1 \) and \( 0 < q \leq \infty \), we define the space \( X_{\theta, q} := (X_0, X_1)_{\theta, q} \) as the set of all \( f \) such that
\[
\| f \|_{X_{\theta, q}} := \| f \|_{X_0 + X_1} + \left( \int_0^\infty [t^{-\theta} K(f, t)]^{q} \frac{dt}{t} \right)^{1/q}
\]
is finite.

We wish to establish a connection between the \( K \)-functional for \( B_0, B_1 \) and the \( K \)-functional for \( l_0, l_1 \). For this, we fix a number \( 0 < \rho \leq p_0, p_1 \) and an integer \( r \) such that \( \alpha_0, \alpha_1 \leq r - 1 \). We let \( P_r(f) \) be the best \( L_\rho(I) \) approximation to \( f \) from polynomials of coordinate degree < \( r \). According to Lemma 3.2, if \( S_k(f) \) is defined by (4.18), and \( T_k(f) \) is defined by (4.20) then \( N_2(f) \) and \( N_3(f) \) of Theorem 5.1 are equivalent to the norm of \( B_\theta^q(L_p) \).

If \( f \in L_p \), we let \( T_f := (t_k(f)) \). In this way, we associate to each \( f \in L_p \) a sequence of dyadic splines and \( f \in B_\theta^q(L_p) \) if and only if \( T_f \in l_\theta^q(L_p) \) and from Theorem 5.1
\[
\| f \|_{B_\theta^q(L_p)} \simeq \| T_f \|_{l_\theta^q(L_p)},
\]
for all \( \alpha, q > 0 \), provided \( p \geq \rho \).

**Theorem 6.1.** There are constants \( c_1, c_2 > 0 \) which depend only on \( p, r, d, \alpha_0, \) and \( \alpha_1 \) such that
\[
(6.4) \quad c_1 K(f, t, B_0, B_1) \leq K(T_f, t, l_0, l_1) \leq c_2 K(f, t, B_0, B_1), \quad t > 0,
\]
whenever \( f \in B_0 + B_1 \).

**Proof of lower inequality.** We suppose that \( \alpha := (a_k) \in l_1 \) is such that \( T_f - \alpha \) is in \( l_0 \). We define \( g_k := T_k(a_k) := Q_k(S_k(a_k)) \) as in (4.20). Then by (4.21), \( \| g_k \|_{p_1} \leq c \| a_k \|_{p_1} \). Now, we let \( g := \sum_0^\infty g_k \) with convergence in \( L_{p_1} \). Since \( \sum_0^\infty g_j \) is in \( \Sigma_k \), we have from (2.3)
\[
s_k(g)_{p_1} \leq \left( \sum_{k+1}^\infty \| g_k \|_{p_1} \right)^{1/\mu}, \quad k = -1, 0, \ldots,
\]
provided \( \mu \leq p_1 \). Here, when \( k = -1 \), \( s_{-1}(f)_p := \| f \|_p \), as usual. If we take also \( \mu \leq q_1 \), we have from the Hardy inequality (5.2) and the equivalence of the norms \( N \) and \( N_1 \) in Theorem 5.1 that
\[
(6.5) \quad \| g \|_{B_1} \leq c \| a \|_{l_1}.
\]
We can prove a similar estimate for $f - g$. Namely,
\begin{equation}
(6.6) \quad s_k(f - g)_{p_0} \leq \left(\sum_{k+1}^\infty (t_j - g_j)_{p_0}^\mu\right)^{1/\mu}.
\end{equation}

Now $t_j = Q_j(t_j)$ because $Q_j$ is a projector. Also since $t_j \in \Pi_j$, we have $S_j(a_j - t_j) = S_j(a_j) - t_j$. Hence,
\[\|t_j - g_j\|_{p_0} = \|Q_j(t_j - S_j(a_j))\|_{p_0} = \|Q_j(S_j(t_j - a_j))\|_{p_0} \leq c\|t_j - a_j\|_{p_0}\]
because of (4.21). If we use our last inequality in (6.6) and then argue as in the proof of (6.5), we obtain
\begin{equation}
(6.7) \quad \|f - g\|_{B_0} \leq c\|Tf - a\|_{t_0}.
\end{equation}

Since $a \in l_1$ is arbitrary, (6.5), (6.7) and the definition of the $K$-functional give the lower inequality in (6.4). \qed

For the proof of the upper inequality in (6.4), we shall need a result about approximation in a quasi-normed space $X$. We suppose that $Z$ is a linear subspace of $X$ such that each element $x \in X$ has a best approximation from $Z$. We let
\begin{equation}
(6.8) \quad E(x) := \inf_{z \in Z} \|x - z\|_X.
\end{equation}
We say that $z$ is a near best approximation to $x$ with constant $A$ if
\begin{equation}
(6.9) \quad \|x - z\| \leq AE(x).
\end{equation}

**Lemma 6.2.** Let $X$ and $Z$ be as above. If $x \in X$ and $z \in Z$ is a near best approximation to $x$ with constant $A$, then for each $y \in X$, there is a $z' \in Z$ such that $z'$ is a near best approximation to $y$ and $z - z'$ is a near best approximation to $x - y$ with constants $c$ depending only on $X$ and $A$.

**Proof.** Let $\gamma$ be such that $\|u + v\| \leq \gamma(\|u\| + \|v\|)$ for all $u, v \in X$ (all norms in this proof are for $X$).

**Case:** $E(x - y) \leq E(y)$. We let $z' := z'' + z$ with $z''$ a best approximation to $y - x$. Then, by definition $z - z'$ is near best for $x - y$ with constant 1. On the other hand,
\[
\|y - z'\| = \|y - z - z''\| \leq \gamma(\|y - x - z''\| + \|x - z\|) \leq \gamma(E(x - y) + AE(x)) \\
\leq \gamma(E(x - y) + \gamma AE(y) + \gamma AE(x - y)) \leq (\gamma + 2\gamma^2 A)E(y).
\]

**Case:** $E(y) \leq E(x - y)$. The same as the previous case with $x - y$ and $y$ interchanged. \qed

**Proof of the upper inequality in (6.4).** We suppose that $g$ is any function in $B_1$ for which $f - g$ is in $B_0$. We let $P_I$ be the polynomials which make up $S_k := S_k(f)$. Then $P_I$ is a best $L_\rho(I)$ approximation to $f$ from polynomials of coordinate degree $< r$. Therefore, we can apply Lemma 6.2 to obtain a near best $L_\rho(I)$ approximation $Q_I$ to $g$ from polynomials of coordinate degree $< r$ such that $P_I - Q_I$ is also a near best $L_\rho(I)$ approximation to $f - g$.

We let $U_k, R_k$ be obtained from $Q_I$ and $P_I - Q_I, I \in D_k$, by using quasi-interpolants in the same way that $T_k$ was defined from the $P_I$. Since $Q_k$ is linear,
we have $R_k = T_k - U_k$. Then, by Corollary 4.7, $U_k$ and $R_k$ are respectively near best $L_p$ and $L_p$ approximations to $g$ and $f - g$ from $\Sigma_k$, $k = 0, 1, \ldots$. We let $t_k := T_k - T_{k-1}$, $u_k := U_k - U_{k-1}$, $r_k := R_k - R_{k-1}$, $k = 0, 1, \ldots$, with our usual convention $R_{-1} := 0$, $U_{-1} := 0$. We then have for $k = 0, 1, \ldots$,

$$
\|u_k\|_{p_1} \leq c\left[s_k(g)_{p_1} + s_{k-1}(g)_{p_1}\right],
$$

$$
\|r_k\|_{p_0} \leq c\left[s_k(f - g)_{p_0} + s_{k-1}(f - g)_{p_0}\right].
$$

With $u := (u_k)$, it follows from Theorem 5.1 that

$$
\|Tf - u\|_{l_0} + t\|u\|_{l_1} \leq c\left[\|f - g\|_{l_0} + t\|g\|_{B_1}\right].
$$

The upper estimate in (6.4) then follows from the definition of the $K$-functional. □

For $B_0, B_1, l_0, l_1$ and $Tf$ as above, we have for any $q > 0$ and $0 < \theta < 1$,

$$
f \in (B_0, B_1)_{\theta, q} \text{ if and only if } Tf \in (l_0, l_1)_{\theta, q}.
$$

(6.10)

$$
\|f\|_{(B_0, B_1)_{\theta, q}} = \|Tf\|_{(l_0, l_1)_{\theta, q}}.
$$

Indeed, this follows immediately from the definition of the spaces $X_{\theta, q}$.

Now (6.10) allows us to deduce information about the interpolation spaces between $B_0$ and $B_1$ from known theorems (see [P, p. 98]) about the interpolation between $l_0$ and $l_1$. The simplest case to describe is when $p_0 = p_1 = p$. We then have

(6.11) \[ (l_{q_0}^{\alpha}(L_p), l_{q_1}^{\alpha}(L_p))_{\theta, q} = l_q^{\alpha}(L_p) \] where $\alpha = \theta \alpha_0 + (1 - \theta)\alpha_1$.

From this, (6.10), and Theorem 5.1, we obtain

**COROLLARY 6.2.** If $0 < \alpha_0, \alpha_1$ and $0 < p, q_0, q_1 \leq \infty$, we have for each $0 < \theta < 1$ and $0 < q \leq \infty$,

(6.12) \[ (B_{q_0}^{\alpha_0}(L_p), B_{q_1}^{\alpha_1}(L_p))_{\theta, q} = B_q^\alpha(L_p), \] with $\alpha := \theta \alpha_0 + (1 - \theta)\alpha_1$.

When $p_0 \neq p_1$, the interpolation spaces between $L_{p_0}$ and $L_{p_1}$ can be described in terms of the Lorentz spaces $L_{p,q}$ (see [B-B, p. 183] for their definition and properties). We have for $0 < q_0, q_1 \leq \infty$ (see [P, p. 98]),

(6.13) \[ (l_0, l_1)_{\theta, q} = l_q^{\alpha}(L_{p,q}) \]

with $\alpha := \theta \alpha_0 + (1 - \theta)\alpha_1$; $1/q := \theta/q_0 + (1 - \theta)/q_1$ and $1/p := \theta/p_0 + (1 - \theta)/p_1$.

In the special case when $q = p$, we have $L_{p,q} = L_p$ and therefore, we obtain

**COROLLARY 6.3.** If $0 < \alpha_0, \alpha_1$ and $0 < p_0, p_1, q_0, q_1 \leq \infty$, then for each $0 < \theta < 1$ and for $1/q := \theta/q_0 + (1 - \theta)/q_1$; $1/p := \theta/p_0 + (1 - \theta)/p_1$, we have

(6.14) \[ (B_{q_0}^{\alpha_0}(L_{p_0}), B_{q_1}^{\alpha_1}(L_{p_1}))_{\theta, q} = B_q^\alpha(L_p), \] with $\alpha := \theta \alpha_0 + (1 - \theta)\alpha_1$, provided $p = q$.

7. An embedding theorem for Besov spaces. As an application of the results of the previous sections, we shall prove Sobolev type embedding theorems for Besov spaces. These have important applications in nonlinear approximation (see [D-P]). We fix a value of $p$ with $0 < p < \infty$. Given $\alpha > 0$, we determine $\sigma$ from the equation

(7.1) \[ 1/\sigma = \alpha/d + 1/p. \]
We shall prove that $B^p_\alpha(L_\sigma)$ is continuously embedded in $L_p$. For this, we shall use the following simple inequality for splines $S \in \Pi_k(r)$:

\begin{equation}
\|[S]_p\| \leq c2^{\alpha p}\|[S]_\sigma\|.
\end{equation}

Indeed, on each cube $I \in D_k$, $S = P$ with $P$ a polynomial of coordinate degree $\leq r$. Hence (see [D-Sh, §3]), $\|[S]_p(I)\| \leq c|I|^{1/p-1/\sigma}\|[S]_\sigma(I)\| = 2^{\alpha p}\|[S]_\sigma(I)\|^{p/\sigma}$, where the last inequality uses the fact that the $l_{\sigma/p}$ norm is larger than the $l_1$ norm because $\sigma/p < 1$.

**Theorem 7.1.** If $\alpha, \sigma, p$ are related as in (7.1), then $B^p_\alpha(L_\sigma)$ is continuously embedded in $L_p$, that is,

\begin{equation}
\|[f]_p\| \leq c\|[f]_{B^p_\alpha(L_\sigma)}\|
\end{equation}

holds for all $f \in B^p_\alpha(L_\sigma)$.

**Proof.** We choose $r > \alpha + 1$ and let $t_j \in \Sigma_j(r)$ be as in Theorem 5.1. Then $f = \sum_{j=0}^\infty t_j$ in the sense of convergence in $L_\sigma$. From (2.3), it follows that for $\mu := \min(1,p)$,

\begin{equation}
\|[f]_p\| \leq c\left(\sum_{j=0}^\infty \|[t_j]_p\|^\mu\right)^{1/\mu} \leq c\left(\sum_{j=0}^\infty (2^{\alpha j}\|[t_j]_\sigma\|)^\mu\right)^{1/\mu} \leq c\|[f]_{B^p_\alpha(L_\sigma)}\|,
\end{equation}

where the second inequality follows from (7.2) and the last from Theorem 5.1.

Inequality (7.4) shows that $B^p_\alpha(L_\sigma)$ is continuously embedded in $L_p$ which is the desired result when $p \leq 1$. When $p > 1$, we choose $1 \leq p_0 < p < p_1 < \infty$ and for $i = 0, 1$, we let $\alpha_i$ be determined by formula (7.1) for $p_i$ and our $\sigma$. Then by (7.4)

\begin{equation}
\|[f]_{p_i}\| \leq c\|[f]_{B^{p_i}_\alpha(L_\sigma)}\|,
\end{equation}

If we now apply Corollary 6.2 with $\theta$ chosen so that $1/p = \theta/p_0 + (1-\theta)/p_1$ and $q := p$, we obtain by interpolation

\begin{equation}
\|[f]_p\| \leq c\|[f]_{B^p_\alpha(L_\sigma)}\|
\end{equation}

with $\alpha' = \theta\alpha_0 + (1-\theta)\alpha_1$. Here, we have used the fact that $L_{p,p} = L_p$. Now using (7.1) for the pairs $(\alpha, p), (\alpha_0, p_0)$ and $(\alpha_1, p_1)$ shows that $\alpha' = \alpha$, as desired. \(\square\)
