THE HIT PROBLEM FOR THE DICKSON ALGEBRA

NGUYỄN H. V. HƯNG AND TRÂN NGỌC NAM

Dedicated to Professor Franklin P. Peterson on the occasion of his 70th birthday

Abstract. Let the mod 2 Steenrod algebra, $A$, and the general linear group, $GL(k, \mathbb{F}_2)$, act on $P_k := \mathbb{F}_2[x_1, \ldots, x_k]$ with $|x_i| = 1$ in the usual manner. We prove the conjecture of the first-named author in Spherical classes and the algebraic transfer, (Trans. Amer. Math. Soc. 349 (1997), 3893–3910) stating that every element of positive degree in the Dickson algebra $D_k := (P_k)^{GL(k, \mathbb{F}_2)}$ is $A$-decomposable in $P_k$ for arbitrary $k > 2$. This conjecture was shown to be equivalent to a weak algebraic version of the classical conjecture on spherical classes, which states that the only spherical classes in $Q_0 \mathbb{S}^0$ are the elements of Hopf invariant one and those of Kervaire invariant one.

1. Introduction

Let $P_k := \mathbb{F}_2[x_1, \ldots, x_k]$ be the polynomial algebra over (the field of two elements) $\mathbb{F}_2$ in $k$ variables, each of degree 1. The general linear group $GL_k := GL(k, \mathbb{F}_2)$ acts on $P_k$ in the usual manner. Dickson proves in [1] that the ring of invariants, $D_k := (P_k)^{GL_k}$, is also a polynomial algebra $D_k \cong \mathbb{F}_2[Q_{k, -1}, \ldots, Q_{k, 0}]$, where $Q_{k, s}$ denotes the Dickson invariant of degree $2^k - 2^s$. It can be defined by the inductive formula

$$Q_{k, s} = Q_{k-1, s-1}^2 + V_k \cdot Q_{k-1, s},$$

where, by convention, $Q_{k, -1} = 1, Q_{k, 0} = 0$ for $s < 0$ and

$$V_k = \prod_{\lambda_j \in \mathbb{F}_2} (\lambda_1 x_1 + \cdots + \lambda_{k-1} x_{k-1} + x_k).$$

Let $A$ be the mod 2 Steenrod algebra. The usual action of $A$ on $P_k$ commutes with that of $GL_k$. So $D_k$ is an $A$-module. One of the authors has been interested in the homomorphism

$$j_k : \mathbb{F}_2 \otimes (P_k)^{GL_k} \to (\mathbb{F}_2 \otimes P_k)^{GL_k} \biggr| A,$$

which is induced by the identity map on $P_k$ (see [3]). Observing that $j_1$ is an isomorphism and $j_2$ is a monomorphism, he sets up the following

Conjecture 1.1 (Nguyễn H. V. Hưng [3]), $j_k = 0$ in positive degrees for $k > 2$.

Let $D^+_k$ and $A^+_k$ denote respectively the submodules of $D_k$ and $A$ consisting of all elements of positive degree. Then Conjecture 1.1 is equivalent to $D^+_k \subset A^+_k \cdot P_k$.

This work was supported in part by the National Research Project, No. 1.4.2.
for $k > 2$ (see [3]). In other words, it predicts that every $GL_k$-invariant element of positive degree is hit by the Steenrod algebra acting on $P_k$ for $k > 2$.

Conjecture 1.1 is related to the hit problem of determination of $\mathbb{F}_2 \otimes P_k$. This problem has first been studied by F. Peterson [9], R. Wood [14], W. Singer [12], and S. Priddy [10], who show its relationships to several classical problems in cobordism theory, modular representation theory, Adams spectral sequence for the stable homotopy of spheres, and stable homotopy type of classifying spaces of finite groups. The tensor product $\mathbb{F}_2 \otimes P_k$ has explicitly been computed for $k \leq 3$. The cases $k = 1$ and 2 are not difficult, while the case $k = 3$ is complicated and was solved by M. Kameko [8]. It seems unlikely that a very explicit description of $\mathbb{F}_2 \otimes P_k$ for general $k$ will appear in the near future. There is also another approach, the qualitative one, to the problem. By this we mean giving conditions on elements of $P_k$ to show that they go to zero in $\mathbb{F}_2 \otimes P_k$, i.e. belong to $\mathcal{A} \cdot P_k$. Peterson’s conjecture, which was established by Wood [14], claims that $\mathbb{F}_2 \otimes P_k = 0$ in degree $d$ such that $\alpha(d + k) > k$. Here $\alpha(n)$ denotes the number of ones in the dyadic expansion of $n$. Recently, W. Singer, K. Monks, and J. Silverman have refined the method of R. Wood to show that many more monomials in $P_k$ are in $\mathcal{A} \cdot P_k$. (See Silverman [11] and its references.) Conjecture 1.1 presents a large family, whose elements are predicted to be in $\mathcal{A} \cdot P_k$.

In [3], one of the authors proves the equivalence of Conjecture 1.1 and a weak algebraic version of the conjecture on spherical classes stating that: There are no spherical classes in $Q_0 S^0$ except the elements of Hopf invariant one and those of Kervaire invariant one. He also gives two proofs of Conjecture 1.1 for the case $k = 3$. In this paper, we establish this conjecture for every $k > 2$. That Conjecture 1.1 is no longer valid for $k = 1$ and 2 is respectively an exposition of the existence of Hopf invariant one classes and Kervaire invariant one classes. We have

**Main Theorem.** $D_k^+ \subset \mathcal{A} \cdot P_k$ for $k > 2$.

Recently, F. Peterson and R. Wood privately informed us that they had proved the theorem for $k = 4$ and probably for $k = 5$. The readers are referred to [3] and [5] for some problems, which are closely related to the main theorem. Additionally, the problem of determination of $\mathbb{F}_2 \otimes D_k$ and its applications have been studied by Hu’ng and Peterson [6, 7].

The paper contains five sections. Section 2 is a preparation on the action of the Steenrod squares on the Dickson algebra. We prove the main theorem in Section 3 by means of two lemmata, which are later shown in Section 4 and Section 5 respectively.

**2. Preliminaries**

The action of the Steenrod squares on $D_k$ is explicitly described as follows.

**Theorem 2.1** ([2]).

$$Sq^i(Q_{k,s}) = \begin{cases} Q_{k,r} & \text{for } i = 2^s - 2^r, \ r \leq s, \\ Q_{k,r} Q_{k,t} & \text{for } i = 2^k - 2^t + 2^s - 2^r, \ r \leq s < t, \\ Q_{k,s}^2 & \text{for } i = 2^k - 2^s, \\ 0 & \text{otherwise.} \end{cases}$$
From now on, we denote $Q_{k,s}$ by $Q_s$ for brevity. We get

$$S q^a(Q_s) = \begin{cases} Q_{s-1} & \text{if } a = 2^{s-1}, \\ 0 & \text{if } 0 < a < 2^{s-1} \text{ or } 2^s \leq a < 2^{k-1} \end{cases}$$

for $0 \leq s < k$. Combining this with the Cartan formula, one obtains

**Corollary 2.2.**

(a) $S q^a(Q_sR) = Q_s S q^a(R)$ if $0 < a < 2^{s-1},$

(b) $S q^a(Q_0R) = Q_0 S q^a(R)$ if $0 < a < 2^{k-1}$

for any polynomial $R \in P_k$.

Let $I_n (n \geq 0)$ be the right ideal of $A$ generated by the operations $S q^a$ for $i = 0, \ldots, n$.

**Definition 2.3.** Suppose $R_1, R_2 \in P_k$. Then we write $R_1 \equiv R_2 \pmod{I_n}$ if $R_1 + R_2$ belongs to $I_n \cdot P_k$. By convention, $R_1 \equiv R_2 \pmod{I_n}$ means $R_1 = R_2$ for $n < 0$.

This is an equivalence relation.

**Lemma 2.4.**

(a) $S q^1(R_1)R_2 \equiv R_1 S q^1(R_2) \pmod{I_0},$

(b) $S q^2(R_1)R_2 \equiv R_1 S q^2(R_2) \pmod{I_1}$

for any polynomials $R_1, R_2 \in P_k$.

**Proof.** (a) From the Cartan formula $S q^1(R_1)R_2 + R_1 S q^1(R_2) = S q^1(R_1R_2)$, we get

(b) We have

$$S q^2(R_1R_2) = S q^2(R_1)R_2 + S q^1(R_1)S q^1(R_2) + R_1 S q^2(R_2)$$

(by the Cartan formula)

$$\equiv S q^2(R_1)R_2 + R_1 S q^1(R_2) + R_1 S q^2(R_2) \pmod{I_0}$$

(by Part (a))

$$\equiv S q^2(R_1)R_2 + R_1 S q^2(R_2) \pmod{I_0}$$

(since $S q^1 S q^1 = 0$).

Hence, $S q^2(R_1)R_2 + R_1 S q^2(R_2) \in I_1 \cdot P_k$ and (b) follows. \hfill \Box

**Lemma 2.5.** Let $R \in P_k$ ($k \geq 1$). If $S q^1(R) = 0$ and all the monomials of $R$ are of positive degree, then $R \equiv 0 \pmod{I_0}$.

**Proof.** The lemma is proved by induction on $k$. For $k = 1$, it is easy to see that all the monomials of $R$ are of even degree. Since $x_1^{2n} = S q^1(x_1^{2n-1})$ for $n > 0$, the lemma is proved. Let $k > 1$ and suppose inductively that the lemma holds for polynomials in $k - 1$ variables. Let us write

$$R = \sum_{0 \leq i \leq 2n} x_i^1 R_i$$

for some positive integer $n$ and some polynomials $R_i$ ($0 \leq i \leq 2n$) in $k - 1$ variables $x_2, \ldots, x_k$. We get

$$S q^1(R) = \sum_{0 \leq i \leq 2n} x_i^1 S q^1(R) + \sum_{0 \leq i \leq 2n \atop i \text{ odd}} x_i^{i+1} R_i$$

$$= S q^1(R_0) + \sum_{0 \leq i \leq 2n \atop i \text{ odd}} x_i^{i+1} S q^1(R_i)$$

$$+ \sum_{0 \leq i \leq 2n \atop i \text{ odd}} x_i^{i+1} [S q^1(R_{i+1}) + R_i].$$
Since \( Sq^1(R) = 0 \), we have \( Sq^1(R_0) = 0 \) and \( Sq^1(R_{i+1}) = R_i \) for \( 0 \leq i \leq 2n \), \( i \) odd. Therefore,

\[
R = \sum_{0 \leq i \leq 2n} x_i^i R_i + \sum_{0 \leq i \leq 2n} x_i^i Sq^1(R_{i+1})
\]

\[
= R_0 + \sum_{0 \leq i \leq 2n} \left[ x_i^{i+1} R_{i+1} + x_i^i Sq^1(R_{i+1}) \right]
\]

\[
= R_0 + Sq^1(\sum_{0 \leq i \leq 2n} x_i^i R_{i+1})
\]

\[
\equiv R_0 \pmod{I_0}
\]

\[
\equiv 0 \pmod{I_0} \quad \text{(by the inductive hypothesis)}.
\]

The lemma is proved. \( \Box \)

This lemma immediately implies that if all monomials of \( R \in P_k \) are of positive degree, then \( R^2 \equiv 0 \pmod{I_0} \).

**Corollary 2.6.** Let \( k > 1 \) and suppose \( S \) is a non-empty subset of \( \{0, \ldots, k-1\} \) such that \( 1 \notin S \). Then

\[
QR^2 \equiv 0 \pmod{I_0},
\]

where \( Q = \prod_{s \in S} Q_s \) and \( R \) is an arbitrary polynomial in \( P_k \).

**Proof.** As \( k > 1 \) and \( 1 \notin S \), one gets \( Sq^1(Q) = 0 \). This implies \( Sq^1(QR^2) = 0 \). Thus \( QR^2 \equiv 0 \pmod{I_0} \) by Lemma 2.5. The corollary is proved. \( \Box \)

### 3. Proof of the Main Theorem

Let \( Q \) be a non-zero Dickson monomial. If \( Q \neq 1 \), it can be written as

\[
Q = \prod_{0 \leq i \leq n} A_i^{\alpha_i},
\]

where \( n \) is some non-negative integer and \( A_i \) is some Dickson monomial dividing \( \prod_{0 \leq s < k} Q_s \) for \( i = 0, \ldots, n \) with \( A_n \neq 1 \).

Indeed, suppose \( Q = \prod_{0 \leq s < k} Q_s^{\alpha_s} \). Since \( Q \neq 1 \), there exists at least one \( \alpha_s \neq 0 \).

Consider the 2-adic expansions of all the non-zero \( \alpha_s \)s:

\[
\alpha_s = \sum_{0 \leq i \leq n(s)} \alpha_{si}2^i,
\]

where \( \alpha_{s\max(s)} = 1 \). Now denoting

\[
n := \max_{\alpha_s \neq 0, 0 \leq s < k} n(s),
\]

\[
\alpha_{si} := 0 \quad \text{if} \quad n(s) < i \leq n \quad (0 \leq s < k),
\]

\[
A_i := \prod_{0 \leq s < k} Q_s^{\alpha_{si}} \quad (0 \leq i \leq n),
\]
one can easily check that \( Q = \prod_{0 \leq i \leq n} A_i^{2^i} \) and each \( A_i \) divides \( \prod_{0 \leq s < k} Q_s \). Moreover, there exists an integer \( r \) such that \( 0 \leq r < k \), \( \alpha_r \neq 0 \) and \( n = n(r) \). Then \( A_n = \prod_{0 \leq s < k} Q_s^{\alpha_{rn}} \) is divisible by \( Q_r^{\alpha_{rn}} = Q_r^{\alpha_{r(n(r))}} = Q_r \), so \( A_n \neq 1 \).

**Definition 3.1.** (i) We call \( n \) the *height* of \( Q \). The monomial \( A_i^{2^i} = A_i(Q)^{2^i} \) is called the \( i \)th cut of \( Q \). It is said to be full if \( A_i \) is divisible by \( \prod_{0 \leq s < k} Q_s \). The monomial \( Q \) is called full if its cuts are all full.

(ii) A Dickson monomial is called a *based cut* if it is the 0th cut of some \( Q \neq 0 \) and \( \neq 1 \).

The main theorem is proved at the end of this section by means of the following two lemmata, whose proofs will be given in the last two sections.

**Lemma A.** Let \( k > 2 \) and suppose \( R \) is an arbitrary polynomial in \( P_k \).

(a) If \( Q = \prod_{0 \leq i \leq n} A_i^{2^i} \neq 1 \) and it is not full, then \( QR^{2^{n+1}} \in A^+ \cdot P_k \).

(b) If \( Q = \prod_{0 \leq i \leq n} A_i^{2^i} \) is full, then \( Q R^{2^{n+1}} \in A^+ \cdot P_k \) for \( 0 \leq m < k - 1 \).

**Lemma B.** Suppose \( k > 2 \). If \( A \) is a full based cut, then \( A \equiv 0 \pmod{I_1} \).

**Proof of the Main Theorem.** Suppose \( Q = \prod_{0 \leq i \leq n} A_i^{2^i} \) is a Dickson monomial with \( A_n \neq 1 \).

If \( Q \) is not full, then applying Lemma A(a) with \( R = 1 \), one gets \( Q \in A^+ \cdot P_k \).

If \( Q \) is full and \( n = 0 \), then \( Q \) is the full based cut of itself. So using Lemma B, one obtains \( Q \equiv 0 \pmod{I_1} \). In particular, \( Q \in A^+ \cdot P_k \).

If \( Q \) is full and \( n > 0 \), then \( A_n \) is the full based cut of itself. By Lemma B, one has \( A_n = Sq^1(R_1) + Sq^2(R_2) \), with some \( R_1, R_2 \in P_k \). Noting that \( Q' = \prod_{0 \leq i < n} A_i^{2^i} \) is also full with the height \( n - 1 \), one can apply Lemma A(b) to it and get

\[
Q' Sq^{2^n}(R_1^n) = \prod_{0 \leq i < n} A_i^{2^i} Sq^{2^n}(R_1^n) \in A^+ \cdot P_k,
\]

\[
Q' Sq^{2^n+1}(R_2^n) = \prod_{0 \leq i < n} A_i^{2^i} Sq^{2^n+1}(R_2^n) \in A^+ \cdot P_k.
\]

(It should be noted that \( 1 < k - 1 \).) Hence

\[
Q = \prod_{0 \leq i < n} A_i^{2^i} \cdot A_n^{2^n} = \prod_{0 \leq i < n} A_i^{2^i} [Sq^{2^n}(R_1^n) + Sq^{2^n+1}(R_2^n)] \in A^+ \cdot P_k.
\]

The proof is completed. \( \square \)

4. **Proof of Lemma A**

In this section, we prove Lemma A by using Lemma 4.1 and Lemma 4.2.

**Lemma 4.1.** Suppose \( k, m, j \) are integers satisfying \( k > 2 \), \( 0 \leq m < k - 1 \) and \( 0 < j \leq 2^m \). Let \( Q \) be a full Dickson monomial of height \( n \) and \( B \) any Dickson monomial of \( Sq^{2^n+1}(Q) \). Suppose \( B = \prod_{0 \leq i < p} B_i^{2^i} \), with \( B_i^{2^i} \) the \( i \)th cut of \( B \) and \( B_p \neq 1 \). We have

(a) \( p \geq n \),

(b) \( B^{2^i} \neq 1 \) for each \( 0 \leq i < p \),

(c) \( B^{2^i} \) is full for each \( 0 \leq i < p \).

(b) \( B^{2^i} \neq 1 \) for each \( 0 \leq i < p \),

(c) \( B^{2^i} \) is full for each \( 0 \leq i < p \).
(b) If $B' = \prod_{0 \leq i \leq n} B_i^2 \neq 1$, then it is not full.

Proof. (a) Suppose to the contrary that $p < n$. We get

$$\deg Q + 2^{n+1} j = \deg \left( \prod_{0 \leq i \leq p} B_i^{2^i} \right)$$

$$\leq \left( \sum_{0 \leq i \leq p} 2^i \right) \deg \left( \prod_{0 \leq s < k} Q_s \right)$$

$$\leq (2^n - 1) \deg \left( \prod_{0 \leq s < k} Q_s \right)$$

and

$$\deg Q + 2^{n+1} j > \deg Q$$

$$\geq \left( \sum_{0 \leq i \leq n} 2^i \right) \deg \left( \prod_{0 \leq s < k} Q_s \right) \quad (\text{since } Q \text{ is full})$$

$$= (2^{n+1} - 1) \deg \left( \prod_{0 \leq s < k} Q_s \right).$$

Therefore,

$$(2^n - 1) \deg \left( \prod_{0 \leq s < k} Q_s \right) > (2^{n+1} - 1) \deg \left( \prod_{0 \leq s < k} Q_s \right),$$

$$(2^n - 1) \deg Q_0 > 2^n \deg \left( \prod_{0 \leq s < k} Q_s \right),$$

$$\deg Q_0 > \deg \left( \prod_{0 \leq s < k} Q_s \right).$$

The last inequality is false for every $k > 2$. This contradiction shows part (a).

(b) Suppose to the contrary that $\prod_{0 \leq i \leq n} B_i^{2^i}$ is full. Then

$$\deg Q + 2^{n+1} j = \deg \left( \prod_{0 \leq i \leq n} B_i^{2^i} \right)$$

$$= \deg \left( \prod_{0 \leq i \leq n} B_i^{2^i} \right) \pmod{2^{n+1}},$$

$$\deg Q - \deg \left( \prod_{0 \leq i \leq n} B_i^{2^i} \right) \equiv 0 \pmod{2^{n+1}},$$

$$\sum_{0 \leq i \leq n} 2^i (\deg A_i - \deg B_i) \equiv 0 \pmod{2^{n+1}}.$$

It is easy to see that $\deg A_i - \deg B_i = \varepsilon_i \deg Q_0$, with $\varepsilon_i \in \{0, 1, -1\}$. Furthermore, if $\varepsilon_i = 0$, then $A_i = B_i$. So $\sum_{0 \leq i \leq n} 2^i \varepsilon_i \deg Q_0 \equiv 0 \pmod{2^{n+1}}$. It should be noted that $\deg Q_0 = 2^k - 1$ has no common divisor with $2^{n+1}$. So $\sum_{0 \leq i \leq n} 2^i \varepsilon_i \equiv 0 \pmod{2^{n+1}}$. This implies $\varepsilon_i = 0$ for $i = 0, \ldots, n$. In other words, $A_i = B_i$ for
\[ i = 0, \ldots, n \text{ and } Q = \prod_{0 \leq i \leq n} B_i^{2^i}. \text{ We have} \]
\[
\deg Q + 2^{n+1}j = \deg( \prod_{0 \leq i \leq n} B_i^{2^i} ) + \deg( \prod_{n < i \leq p} B_i^{2^i} )
\]
\[
= \deg Q + \deg( \prod_{n < i \leq p} B_i^{2^i} ),
\]
\[
2^{n+1}j = \deg( \prod_{n < i \leq p} B_i^{2^i} ) \geq \deg B_p^{2^p}.
\]

Since \( j > 0 \), we get \( \deg B = \deg Q + 2^{n+1}j > \deg Q \), so \( p > n \). Hence
\[
\deg B_p^{2^p} \geq \deg B_p^{2^{n+1}} \geq \deg B_p^{2^{n+1}} = 2^{n+1} \cdot 2^{k-1}.
\]

It implies \( j \geq 2^{k-1} \). Combining this and the fact \( 2^{k-1} > 2m \geq j \), we obtain \( j > j \).

This contradiction comes from the hypothesis that \( B' \) is full. Therefore, the lemma is proved.

**Lemma 4.2.** Let \( A \neq 1 \) be an unfull based cut. Denote by \( s \) the smallest integer \( s \geq 1 \) such that \( Q_s \not\mid A \). If \( s > 1 \), then there exists for every \( R \in P_k \) an expansion
\[
AR^2 = S\eta^{2^s-1}(R_1) + \sum B R_2^2,
\]
where \( R_1 \in P_k \), every \( R_2 \in P_k \) and every \( B \) is a Dickson monomial with \( B \mid \prod_{0 \leq r < k} Q_r \), \( B \neq 1 \), \( Q_{s-1} \not\mid B \).

**Proof.** From the hypothesis we can write \( A = \tilde{A} \prod_{0 < r < s} Q_r \) with a certain Dickson monomial \( \tilde{A} \mid \prod_{s < r < k} Q_r Q_0 \). By the Cartan formula
\[
S\eta^{2^s-1}(\tilde{A} Q_s \prod_{0 < r < s-1} Q_r) R^2 = S\eta^{2^s-1}(\tilde{A} Q_s \prod_{0 < r < s-1} Q_r) R^2
\]
\[
+ \sum_{0 \leq j < 2^{s-2}} S\eta^{2j}(\tilde{A} Q_s \prod_{0 < r < s-1} Q_r) S\eta^{2^s-2j}(R^2).
\]

Denoting \( R_1 := \tilde{A} Q_s \prod_{0 < r < s-1} Q_r R^2 \), we get
\[
S\eta^{2^s-1}(\tilde{A} Q_s \prod_{0 < r < s-1} Q_r) R^2 = S\eta^{2^s-1}(R_1)
\]
\[
+ \sum_{0 \leq j < 2^{s-2}} S\eta^{2j}(\tilde{A} Q_s \prod_{0 < r < s-1} Q_r) S\eta^{2^s-2j}(R^2).
\]

We will prove that (a) \( A = S\eta^{2^s-1}(\tilde{A} Q_s \prod_{0 < r < s-1} Q_r) \) and that (b) every polynomial \( S\eta^{2j}(\tilde{A} Q_s \prod_{0 < r < s-1} Q_r) S\eta^{2^s-2j}(R^2) \) for \( 0 \leq j < 2^{s-2} \) can be written in the form \( \sum B R_2^2 \), where \( B, R_2 \) satisfy the conclusions of Lemma 4.2. Thus, the required expansion will be obtained.

First we prove (a). By Corollary 2.2 we have
\[
S\eta^{2^s-1}(\tilde{A} Q_s \prod_{0 < r < s-1} Q_r) = \tilde{A} S\eta^{2^s-1}(Q_s \prod_{0 < r < s-1} Q_r).
\]
So it suffices to show that $Sq^{2r-1}(Q_s \prod_{0<r<s-1} Q_r) = \prod_{0<r<s} Q_r$. By the Cartan formula

$$Sq^{2r-1}(Q_s \prod_{0<r<s-1} Q_r) = Q_s Sq^{2r-1}( \prod_{0<r<s-1} Q_r)$$

$$+ \sum_{0<r<s-1} Sq^a(Q_s) Sq^{2r-1-a}( \prod_{0<r<s-1} Q_r)$$

$$= Q_s Sq^{2r-1}( \prod_{0<r<s-1} Q_r) + Q_{s-1} \prod_{0<r<s-1} Q_r$$

(since $Sq^a(Q_s) = 0$ for $0 < a < 2s-1$)

and $Sq^{2r-1}(Q_s) = Q_{s-1}$

$$= Q_s Sq^{2r-1}( \prod_{0<r<s-1} Q_r) + \prod_{0<r<s} Q_r.$$  

It is sufficient to prove $Sq^{2r-1}( \prod_{0<r<s-1} Q_r) = 0$. Note that, by the Cartan formula,

$$Sq^{2r-1}( \prod_{0<r<s-1} Q_r) = \sum_{0<r<s-1} \prod_{0<r<s-1} Sq^{a_r}(Q_r),$$

where the sum is taken over all $(a_r)_{0<r<s-1}$ satisfying $\sum_{0<r<s-1} a_r = 2s-1$ and $a_r \geq 0$.

It is easy to show that there exists an $r$ such that $0 < r < s-1$ and $a_r > 2r$. Since $a_r \leq 2s-1 < 2k-1$, we have $2r < a_r < 2k-1$. So, by Theorem 2.1, $Sq^{a_r}(Q_r) = 0$. Hence $\prod_{0<r<s-1} Sq^{a_r}(Q_r) = 0$. This is true for every $(a_r)_{0<r<s-1}$, so $Sq^{2r-1}( \prod_{0<r<s-1} Q_r) = 0$. Part (a) is shown.

Next we prove (b). From Corollary 2.2 and since $2j < 2s-1 < 2k-1$ we have

$$Sq^{2j}(\bar{A}Q_s \prod_{0<r<s-1} Q_r) = \bar{A}Q_s Sq^{2j}( \prod_{0<r<s-1} Q_r).$$

By the Cartan formula we get

$$Sq^{2j}( \prod_{0<r<s-1} Q_r) = \sum_{0<r<s-1} \prod_{0<r<s-1} Sq^{j_t}(Q_r),$$

where the sum is taken over all sequences $(j_r)_{0<r<s-1}$ satisfying $\sum_{0<r<s-1} j_r = 2j$ and $j_r \geq 0$. From Theorem 2.1 and since $j_r \leq 2j < 2k-1$ we have $Sq^{j_t}(Q_r)$ is either 0 or $Q_t$ with $0 \leq t \leq r$. So $\prod_{0<r<s-1} Sq^{j_t}(Q_r)$ is not divisible by $Q_{s-1}, Q_s, \ldots, Q_{k-1}$.

Therefore, the 0th cut of every Dickson monomial in $Sq^{2j}( \prod_{0<r<s-1} Q_r)$ is not divisible by $Q_{s-1}, Q_s, \ldots, Q_{k-1}$. Let us write $Sq^{2j}( \prod_{0<r<s-1} Q_r)$ as the sum of its Dickson monomials $Sq^{2j}( \prod_{0<r<s-1} Q_r) = \sum \prod_{0<r<s-1} C^2_i$, where $C^2_i$ is an 0th cut. Then

$$Sq^{2j}(\bar{A}Q_s \prod_{0<r<s-1} Q_r) = \bar{A}Q_s Sq^{2j}( \prod_{0<r<s-1} Q_r)$$

$$= \sum \bar{A}Q_s C_0 \prod_{0<r<s-1} C^2_i.$$
We have shown that $C_0$ is not divisible by $Q_{s-1}, Q_{s}, \ldots, Q_{s-1}$. Note that $\deg Q_0$ is odd, while $\deg Q_r$ is even for every $r > 0$. Thus, the 0th cut $C_0$ of every term in $Sq^{2j}(\prod_{0 < r < s - 1} Q_r)$ is not divisible by $Q_0$. Recall that $A$ is a divisor of $\prod_{s < r < k} Q_r Q_0$. So $\tilde{A}Q_0 C_0$ is not divisible by $Q_{s-1}$. Moreover, it is a Dickson monomial, which is different from 1 and divides $\prod_{0 < r < k} Q_r$.

Putting $B := \tilde{A}Q_0 C_0$ and $R_2 := \prod_{0 < i < p} C_i^{2^{i-1}} Sq^{2^{i-2} - j}(R)$ for each $C_0$, we get

$$Sq^{2j}(\tilde{A}Q_0 \prod_{0 < r < s - 1} Q_r) Sq^{2^{r-1} - 2j}(R^2) = \sum_{0 < i < p} \tilde{A}Q_0 C_0 \prod_{0 < i < p} C_i^{2i} Sq^{2^{i-1} - 2j}(R^2) = BR_2^2.$$  

It has been shown that $B = \tilde{A}Q_0 C_0$ satisfies the conclusions of Lemma 4.2. Hence, part (b) and therefore Lemma 4.2 is proved. \qed

**Proof of Lemma A.** The proof is divided into 2 steps.

**Step 1.** If Lemma A(a) is true for every $n \leq N$, then so is Lemma A(b) for every $n \leq N$.

Indeed, suppose $Q = \prod_{0 \leq i \leq n} A_i^{2^i}$ (with $n \leq N$) is full and $m$ satisfies $0 \leq m < k-1$.

One needs to prove $QSq^{2^{m+n+1}}(R^{2^{n+1}}) \in A^+ \cdot P_k$, where $R \in P_k$. Recall that

$$Sq^n(R^{2^n}) = \begin{cases} [Sq^{n/2^n}(R)]^{2^n} & \text{if } 2^n \mid a, \\ 0 & \text{otherwise.} \end{cases}$$

Then, by the Cartan formula, one gets

$$Sq^{2^{m+n+1}}(QR^{2^{n+1}}) = \sum_{0 \leq j \leq 2^m} Sq^{2^{n+1}j}(Q) Sq^{2^n+1}(2^n - j)(R^{2^{n+1}}) = Q Sq^{2^{m+n+1}}(R^{2^{n+1}}) + \sum_{0 < j \leq 2^m} Sq^{2^{n+1}j}(Q) R_j^{2^{n+1}},$$

where $R_j := Sq^{2^{m-j}}(R)$ for $j = 1, \ldots, 2^m$.

In order to prove that $QSq^{2^{m+n+1}}(R^{2^{n+1}})$ is $A$-decomposable, it suffices to show that each $Sq^{2^{m+n+1}j}(Q) R_j^{2^{n+1}}$ is $A$-decomposable. We do this by showing $BR_j^{2^{n+1}} \in A^+ \cdot P_k$ for every Dickson monomial $B$ of $Sq^{2^{m+n+1}j}(Q)$. Let $B = \prod_{0 \leq i \leq p} B_i^{2^i}$, with $B_i^{2^i}$ the $i$th cut of $B$. By Lemma 4.1(a), we have $p \geq n$. If $\prod_{0 \leq i \leq p} B_i^{2^i} = 1$, then $p > n$, so

$$BR_j^{2^{n+1}} = (\prod_{n \leq i \leq p} B_i^{2^{i-1}} R_i^{2^n})^2 \equiv 0 \pmod{I_0}.$$  

If $\prod_{0 \leq i \leq n} B_i^{2^i} \neq 1$, then it is not full by Lemma 4.1(b). So we can choose an integer $q$ such that $B_q \neq 1 (0 \leq q \leq n \leq N)$ and $\prod_{0 \leq i \leq q} B_i^{2^i}$ is not full. Applying Lemma A(a) to $\prod_{0 \leq i \leq q} B_i^{2^i}$, we obtain

$$BR_j^{2^{n+1}} = \prod_{0 \leq i \leq q} B_i^{2^i} \prod_{q < i \leq p} B_i^{2^{i-q-1}} R_j^{2^{n+1}} R_j^{2^{n+1}} \in A^+ \cdot P_k.$$  

Therefore, Step 1 is shown.

**Step 2.** Lemma A(a) holds for every non-negative integer $n$. 
Let \( q = q(Q) \) be the smallest integer so that \( A_q \) is not full \((0 \leq q \leq n)\). Setting 
\[ R := \prod_{q < i \leq n} A_i^{2^{i-q-1}} R^{n-i}, \]
we have 
\[ QR^{2^{n+1}} = \prod_{0 \leq i < q} A_i^{2^i} R^{2^{q-i+1}}. \]

Let \( s \) be the smallest integer with \( 0 < s < k \) such that \( Q_s \nmid A_q \).

We first notice that Lemma A(a) is true if \( q(Q) = 0 \). This is proved by induction on \( s \). For \( s = 1 \), we have \( A_q R^2 \equiv 0 \pmod{I_0} \). Indeed, if \( A_q = 1 \), then every monomial of \( R \) is of positive degree, so \( A_q R^2 = R^2 \equiv 0 \pmod{I_0} \); if \( A_q \neq 1 \), then 
\[ A_q R^2 \equiv 0 \pmod{I_0} \] by Corollary 2.3. Therefore, 
\[ QR^{2^{n+1}} = A_q R^2 \in A^+ \cdot P_k. \]
The case \( s = 1 \) is proved. Suppose \( s > 1 \) and the assertion holds for \( s-1 \). Then \( A_q \neq 1 \). By Lemma 4.2, we get 
\[ QR^{2^{n+1}} = A_q R^2 = S_q^{2^{s-1}}(R_1) + \sum BR_2^2. \]

Since \( Q_{s-1} \not| B \), by the inductive hypothesis on \( s \), we have \( BR_2^2 \in A^+ \cdot P_k \). This is true for every term \( BR_2^2 \), so 
\[ QR^{2^{n+1}} \in A^+ \cdot P_k. \]

We now prove Step 2 by induction on \( n \). For \( n = 0 \), we have \( q(Q) = 0 \), so Lemma A(a) is true by the above remark. Suppose \( n > 1 \) and Lemma A(a) holds for every smaller value of \( n \). Using the above remark, it suffices to consider the case 
\( q = q(Q) > 0 \). Again, the proof proceeds by induction on \( s \).

For \( s = 1 \), we have seen that 
\[ A_q R^2 \equiv 0 \pmod{I_0}. \]
In other words, 
\[ A_q R^2 = S_q^1(R_1) \] for some \( R_1 \in P_k \). Then 
\[ QR^{2^{n+1}} = \prod_{0 \leq i < q} A_i^{2^i} (A_q R^2)^{2^i} = \prod_{0 \leq i < q} A_i^{2^i} S_q^{2^i} (R_1^{2^i}). \]

Note that \( \prod_{0 \leq i < q} A_i^{2^i} \) is full. By Step 1 and the inductive hypothesis on \( n \), we can apply Lemma A(b) to the element 
\[ \prod_{0 \leq i < q} A_i^{2^i} S_q^{2^i} (R_1^{2^i}) \] of height \( q-1 < n \). This gives 
\[ \prod_{0 \leq i < q} A_i^{2^i} S_q^{2^i} (R_1^{2^i}) \in A^+ \cdot P_k. \]

Thus, the case \( s = 1 \) is proved.

Suppose \( s > 1 \) and the assertion holds for every smaller value of \( s \). Since \( A_q \neq 1 \), by Lemma 4.2, we get 
\[ A_q R^2 = S_q^{2^{s-1}}(R_1) + \sum BR_2^2. \] So 
\[ QR^{2^{n+1}} = \prod_{0 \leq i < q} A_i^{2^i} (A_q R^2)^{2^i} \]
\[ = \prod_{0 \leq i < q} A_i^{2^i} S_q^{2^{i+s-1}} (R_1^{2^i}) + \sum \prod_{0 \leq i < q} A_i^{2^i} B^{2^i} R_2^{2^{i+1}}. \]

By Step 1 and the inductive hypothesis on \( n \), we have 
\[ \prod_{0 \leq i < q} A_i^{2^i} S_q^{2^{i+s-1}} (R_1^{2^i}) \in A^+ \cdot P_k. \]

On the other hand, as \( B \) is a cut that is not divisible by \( Q_{s-1} \), by using the inductive hypothesis on \( s \) we get 
\[ \prod_{0 \leq i < q} A_i^{2^i} B^{2^i} R_2^{2^{i+1}} \in A^+ \cdot P_k. \]

Step 2 is proved. Then, Lemma A follows. \( \square \)
5. Proof of Lemma B

By the hypothesis, \( A = \prod_{0 < s < k} Q_s Q_0^\alpha \), with \( \alpha \in \{0, 1\} \). We need to prove \( A \equiv 0 \) (mod \( I_0 \)). To this end, by means of Corollary 2.2 and the hypothesis \( k > 2 \), it suffices to show \( Q_2 Q_1 \equiv 0 \) (mod \( I_1 \)). From [7, Theorem 2.2], we get

\[
Q_1 = \sum_{\alpha_1 + \ldots + \alpha_k = 2, \alpha_i \geq 0 \text{ or power of 2}} x_1^{\alpha_1} \ldots x_k^{\alpha_k} \\
= \sum_{\text{sym}} x_1 x_2 x_3^4 \ldots x_k^{2^k-1} + \sum_{\text{sym}} x_1^2 x_2^2 x_3^8 \ldots x_k^{2^k-1} + R^2,
\]

where \( \sum_{\text{sym}} \) denotes the sum of all symmetrized terms in \( x_1, \ldots, x_k \), and \( R \) is some polynomial, whose monomials are all of positive degree. By Lemma 2.5, \( R^2 \equiv 0 \) (mod \( I_0 \)). We obtain

\[
Q_1 \equiv \sum_{\text{sym}} (x_1 x_2 x_3^4 \ldots x_k^{2^k-1} + x_1^2 x_2^2 x_3^8 \ldots x_k^{2^k-1}) \quad (\text{mod } I_0)
\]

\[
= Sq^2 \left( \sum_{\text{sym}} x_1 x_2 x_3^8 \ldots x_k^{2^k-1} \right) \quad (\text{mod } I_0)
\]

\[
= Sq^2 Sq^1 \left( \sum_{\text{sym}} x_1 x_2 x_3 x_4^8 \ldots x_k^{2^k-1} \right) \quad (\text{mod } I_0)
\]

\[
= Sq^2 Sq^1 (R_1) \quad (\text{mod } I_0),
\]

where \( R_1 := \sum_{\text{sym}} x_1 x_2 x_3 x_4^8 \ldots x_k^{2^k-1} \). Writing \( Q_1 = Sq^2 Sq^1 (R_1) + Sq^1 (R_2) \) for some \( R_2 \in P_k \), we get

\[
Q_2 Q_1 = Q_2 Sq^2 Sq^1 (R_1) + Q_2 Sq^1 (R_2)
\]

\[
= R_1 Sq^1 Sq^2 (Q_2) + R_2 Sq^1 (Q_2) \quad (\text{mod } I_1) \quad \text{(by Lemma 2.4)}
\]

\[
= R_1 Q_0 \quad (\text{mod } I_1) \quad \text{(by Corollary 2.2)}.
\]

On the other hand, by [7, Theorem 2.2], we have

\[
Q_0 = \sum_{\text{sym}} x_1^2 x_2^4 x_3 \ldots x_k^{2^k-1} = Sq^2 \left( \sum_{\text{sym}} x_1^2 x_2^2 x_3^8 \ldots x_k^{2^k-1} \right)
\]

\[
= Sq^2 Sq^2 \left( \sum_{\text{sym}} x_1 x_2 x_3 x_4^8 \ldots x_k^{2^k-1} \right) = Sq^2 Sq^2 (R_1).
\]

Therefore,

\[
Q_2 Q_1 \equiv R_1 Q_0 \quad (\text{mod } I_1) \equiv R_1 Sq^2 Sq^2 (R_1) \quad (\text{mod } I_1)
\]

\[
= Sq^2 (R_1) Sq^2 (R_1) \quad (\text{mod } I_1) \quad \text{(by Lemma 2.4 b))}
\]

\[
= [Sq^2 (R_1)]^2 \quad (\text{mod } I_1) \equiv 0 \quad (\text{mod } I_1).
\]

Lemma B is proved. \( \Box \)
