THE COMPLEX CROWN
FOR HOMOGENEOUS HARMONIC SPACES

ROBERTO CAMPORESI AND BERNHARD KRÖTZ

ABSTRACT. The complex crown of a noncompact Riemannian symmetric space
$X = G/K$ is generalized to the case of homogeneous harmonic spaces $S = N A$. We prove that every
eigenfunction of the Laplace-Beltrami operator on $S$ extends holomorphically to the crown, and that the
crown is the maximal $S$-invariant domain in $S_C$ with this property.

1. Introduction

Let $X$ be a simply connected homogeneous harmonic Riemannian space. Then
according to [7], Corollary 1.2, $X$ is isometric (up to scaling of the metric) to one
of the following spaces:

(i) $\mathbb{R}^n$.
(ii) $S^n$, $P^k(\mathbb{C})$, $P^l(\mathbb{H})$, or $P^2(\mathbb{D})$, i.e., a compact rank one symmetric space.
(iii) $H^n(\mathbb{R})$, $H^k(\mathbb{C})$, $H^l(\mathbb{H})$, or $H^2(\mathbb{D})$, i.e., a noncompact rank one symmetric space.
(iv) A solvable Lie group $S = A \ltimes N$, where $N$ is of Heisenberg-type and
$A \simeq \mathbb{R}^+$ acts on $N$ by anisotropic dilations preserving the grading.

We denote by $\mathcal{L}$ the Laplace-Beltrami operator on $X$. In case (i), $\mathcal{L}$-eigenfunc-
tions on $\mathbb{R}^n$ extend to holomorphic functions on $\mathbb{C}^n$. Likewise, in case (ii), $\mathcal{L}$-
eigenfunctions on $X = U/K$ admit a holomorphic continuation to the whole affine
complexification $X_C = U_C/K_C$ of $X$. This is no longer true in case (iii). However, in
this case, and more generally for a noncompact Riemannian symmetric space of any
rank $X = G/K$, there exists a unique $G$-invariant domain $\text{Cr}(X)$ of $X_C = G_C/K_C$
containing $X$, the complex crown, with the following property ([13], [11]):
Every $\mathcal{L}$-eigenfunction on $X$ admits a holomorphic extension to $\text{Cr}(X)$, and this
domain is maximal for this property.

The objective of this paper is to obtain an analogous theory for the spaces in
(iv) above.

We note that all spaces in (iii), except for $H^n(\mathbb{R})$, fall into class (iv) by identifying
the symmetric space $X = G/K$ with the $NA$-part in the Iwasawa decomposition
$G = NAK$ of a noncompact simple Lie group $G$ of real rank one, and by suitably
scaling the metric.

Our investigations start with a new model of the crown domain for the rank
one symmetric spaces $X$. We describe $\text{Cr}(X)$ in terms of the Iwasawa coordinates
$A$ and $N$ only. Henceforth we refer to this new model as the mixed model of the
crown. In section 2 we provide the mixed model for the two basic cases, i.e., the symmetric spaces associated with the groups \( G = \text{Sl}(2, \mathbb{R}) \) and \( G = \text{SU}(2, 1) \).

Starting from the two basic cases, reduction of symmetry allows us to obtain a mixed model for all rank one symmetric spaces and motivates a definition of \( \text{Cr}(S) \) for the remaining spaces in (iv). This is worked out in section 3.

Finally, in section 4, we use recent results from [11] to prove the holomorphic extension of \( L \)-eigenfunctions on \( S \) to the crown domain \( \text{Cr}(S) \) and establish maximality of \( \text{Cr}(S) \) with respect to this property.

2. Mixed model for the crown domain

The crown domain can be realized inside the complexification of an Iwasawa \( AN \)-group. The goal of this section is to make this explicit for the rank one groups \( \text{Sl}(2, \mathbb{R}) \) and \( \text{SU}(2, 1) \).

2.1. Notation for rank one spaces. Let \( G \) be a connected semi-simple Lie group of real rank one. We assume that \( G \subset G^\mathbb{C} \), where \( G^\mathbb{C} \) is the universal complexification of \( G \), and that \( G^\mathbb{C} \) is simply connected. We fix an Iwasawa decomposition \( G = NAK \) and form the Riemannian symmetric space \( X = G/K \).

The Cartan involution \( \theta \) on \( G \) associated to \( K \) extends holomorphically to \( G^\mathbb{C} \), say \( \theta^\mathbb{C} \), and the \( \theta^\mathbb{C} \)-fixed points will be denoted by \( K^\mathbb{C} \). We arrive at a totally real embedding \( X \hookrightarrow X^\mathbb{C} := G^\mathbb{C}/K^\mathbb{C}, gK \mapsto gK^\mathbb{C} \).

Let \( x_0 = K^\mathbb{C} \in X \) be the base-point.

Let \( g, k, a \) and \( n \) be the Lie algebras of \( G, K, A \) and \( N \). Let \( \Sigma^+ = \Sigma(a, n) \) be the set of positive roots and put

\[
\Omega := \{ Y \in a | \forall \alpha \in \Sigma^+ \ | \alpha(Y) | < \pi / 2 \}.
\]

Note that \( \Omega \) is a symmetric interval in \( a \simeq \mathbb{R} \). The crown domain of \( X \) is defined as

\[\text{Cr}(X) := G \exp(i\Omega) \cdot x_0 \subset X^\mathbb{C}.\]

Let us point out that \( \Omega \) is invariant under the Weyl group \( W = N_K(A)/Z_K(A) \simeq \mathbb{Z}_2 \) and that \( \exp(i\Omega) \) consists of elliptic elements in \( G^\mathbb{C} \). We will refer to (2.1) as the elliptic model of \( \text{Cr}(X) \) (see [13] for the basic structure theory in these coordinates).

Let us define a domain \( \Lambda \) in \( n \) by

\[\Lambda := \{ Y \in n | \exp(iY) \cdot x_0 \in \text{Cr}(X) \}, \]

where \( \cdot \) refers to the connected component of \( \cdot \) which contains 0.

The set \( \Lambda \) is explicitly determined in [10], Th. 8.11. Further by [10], Th. 8.3, we have

\[\text{Cr}(X) = G \exp(i\Lambda) \cdot x_0.\]

We refer to (2.2) as the unipotent model of \( \text{Cr}(X) \).

Finally let us mention the fact that \( \text{Cr}(X) \subset N_\mathbb{C}A_\mathbb{C} \cdot x_0 \), which brings us to the question of whether \( \text{Cr}(X) \) can be expressed in terms of \( A, N, \Omega \) and \( \Lambda \). This is indeed the case and will be considered in the following two subsections for the groups \( \text{Sl}(2, \mathbb{R}) \) and \( \text{SU}(2, 1) \).
2.2. Mixed model for the upper half plane. Let
\[ G = \text{Sl}(2, \mathbb{R}) \quad \text{and} \quad G_C = \text{Sl}(2, \mathbb{C}). \]

Our choices of \( A, N \) and \( K \) are as follows:

\[
A = \left\{ a_t = \begin{pmatrix} t & 0 \\ 0 & 1/t \end{pmatrix} \mid t > 0 \right\},
\]

\[
A_C = \left\{ a_z = \begin{pmatrix} z & 0 \\ 0 & 1/z \end{pmatrix} \mid z \in \mathbb{C}^* \right\},
\]

\[
K = \text{SO}(2, \mathbb{R}), \quad K_C = \text{SO}(2, \mathbb{C}),
\]

and

\[
N = \left\{ n_x = \begin{pmatrix} 1 & x \\ 0 & 1 \end{pmatrix} \mid x \in \mathbb{R} \right\},
\]

\[
N_C = \left\{ n_z = \begin{pmatrix} 1 & z \\ 0 & 1 \end{pmatrix} \mid z \in \mathbb{C} \right\}.
\]

We will identify \( X = G/K \) with the upper half plane \( H = \{ z \in \mathbb{C} \mid \text{Im} \, z > 0 \} \) via the map

\[
(2.3) \quad X \to \mathbb{H}, \quad gK \mapsto (\frac{ai + b}{ci + d}) \quad \left( g = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \right).
\]

Note that \( x_0 = i \) within our identification.

We view \( X = \mathbb{H} \) inside of the complex projective space \( \mathbb{P}^1(\mathbb{C}) = \mathbb{C} \cup \{ \infty \} \) and note that \( \mathbb{P}^1(\mathbb{C}) \) is homogeneous for \( G_C \) with respect to the usual fractional linear action:

\[
g(z) = \frac{az + b}{cz + d} \quad \left( z \in \mathbb{P}^1(\mathbb{C}), \quad g = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in G_C \right).
\]

Let us remark that the map

\[
X_C \to \mathbb{P}^1(\mathbb{C}) \times \mathbb{P}^1(\mathbb{C}) \setminus \text{diag}, \quad gK_C \mapsto (g(i), g(-i))
\]

is a \( G_C \)-equivariant holomorphic diffeomorphism. In the sequel we will identify \( X_C \) with \( \mathbb{P}^1(\mathbb{C}) \times \mathbb{P}^1(\mathbb{C}) \setminus \text{diag}, \) and emphasize that within this identification the embedding of (2.3) becomes

\[
X \hookrightarrow X_C, \quad z \mapsto (z, \bar{z}).
\]

We will denote by \( \overline{X} \) the lower half plane, and note that the crown domain for \( \text{Sl}(2, \mathbb{R}) \) is given by

\[
\text{Cr}(X) = X \times \overline{X}.
\]

We note that

\[
\Omega = \left\{ \begin{pmatrix} x & 0 \\ 0 & -x \end{pmatrix} \mid x \in (-\pi/4, \pi/4) \right\}
\]

and

\[
\Lambda = \left\{ \begin{pmatrix} 0 & x \\ 0 & 0 \end{pmatrix} \mid x \in (-1, 1) \right\}.
\]

With that we come to the mixed model for the crown which combines both parametrizations in an unexpected way.

We let \( F := \{ \pm 1 \} \) be the center of \( G \) and note that

\[
N_C A_C \cdot x_0 = \mathbb{C} \times \mathbb{C} \setminus \text{diag},
\]
and
\[ N_C A \cdot x_0 \simeq N_C A / F. \]

**Proposition 2.1.** Let \( G = \text{Sl}(2, \mathbb{R}) \). Then the map
\[ NA \times \Omega \times \Lambda \to \text{Cr}(X), \quad (na, H, Y) \mapsto na \exp(iH) \exp(iY) \cdot x_0 \]
is an \( AN \)-equivariant diffeomorphism.

**Proof.** By the facts listed above we only have to show that the map is defined and onto. For that we first note that
\[ \exp(i\Lambda) \cdot x_0 = \{ ((1 + t)i, -(1 - t)i) \mid t \in (-1, 1) \}, \]
and thus
\[ A \exp(i\Lambda) = i\mathbb{R}^+ \times -i\mathbb{R}^+. \]
Consequently,
\[ A \exp(i\Omega) \exp(i\Lambda) \cdot x_0 = \{ (z, w) \in \text{Cr}(X) \mid \arg(w) = -\pi + \arg(z) \}, \]
and finally
\[ NA \exp(i\Omega) \exp(i\Lambda) \cdot x_0 = \text{Cr}(X), \]
as asserted. \( \square \)

### 2.3. Mixed model for \( \text{SU}(2, 1) \)

Let \( G = \text{SU}(2, 1) \) and \( G_C = \text{Sl}(3, \mathbb{C}) \). We let \( G_C \) act on \( \mathbb{P}^2(\mathbb{C}) = (\mathbb{C}^3 \setminus \{0\} / \sim) \) by projectivized linear transformations. We embed \( \mathbb{C}^2 \) into \( \mathbb{P}^2(\mathbb{C}) \) via \( z \mapsto [z, 1] \). Then \( G \) preserves the ball
\[ X = \{ z \in \mathbb{C}^2 \mid \|z\|_2 < 1 \} \simeq G / K, \]
with the maximal compact subgroup \( K = S(U(2) \times U(1)) \) stabilizing the origin \( x_0 = 0 \in X \). Note that an element
\[ g = \begin{pmatrix} A & u \\ v^t & \alpha \end{pmatrix} \in G, \]
with \( u, v \in \mathbb{C}^2 \), acts on \( z \in X \) by
\[ g(z) = \frac{Az + u}{v^t \cdot z + \alpha}. \]

Let \( \tau : G_C \to G_C \) be the holomorphic involution with fixed point set \( \text{SO}(2, 1; \mathbb{C}) \). In the sequel we will view \( \mathbb{P}^2(\mathbb{C}) \times \mathbb{P}^2(\mathbb{C}) \) as a \( G_C \)-space with the twisted action
\[ g \cdot (z, w) = (g(z), \tau(g)(w)) \quad (z, w \in \mathbb{P}^2(\mathbb{C}); g \in G_C). \]

Now, as \( X \) is Hermitian, the crown is given by the double (see [13], Th. 7.7)
\[ \text{Cr}(X) = X \times X, \]
but with \( X \) embedded in \( \text{Cr}(X) \) as \( z \mapsto (z, \bar{z}) \). Note that this embedding is \( G \)-equivariant. Let
\[ A = \left\{ a_t := \begin{pmatrix} \cosh t & 0 & \sinh t \\ 0 & 1 & 0 \\ \sinh t & 0 & \cosh t \end{pmatrix} \mid t \in \mathbb{R} \right\}, \]
set \( Y_t := \log a_t \), and note that
\[ \Omega = \{ Y_t \mid -\pi/4 < t < \pi/4 \}. \]
According to [10], Th. 8.11, we have

\[ \Lambda = \left\{ Z_{a,b} := \begin{pmatrix} ib & a & -ib \\ -a & 0 & a \\ ib & a & -ib \end{pmatrix} \mid a \in \mathbb{C}, b \in \mathbb{R}; \right\} \]

\[ |a|^2 + |b| < 1/2 \].

We now define a subset \( D \subset a \times n \) by

\[ D := \{(Y_t, Z_{a,b}) \in a \times n \mid (1 - 2|a|^2 - 2|b|) \cos(2t) > (1 - \cos(2t))|a|^2 \} \].

If \( \pi_a : a \times n \to a \) denotes the first coordinate projection and \( \pi_n \) resp. the second, we record:

- \( D \subset \Omega \times \Lambda \),
- \( \pi_a(D) = \Omega \),
- \( \pi_n(D) = \Lambda \).

In the coordinates \((2a, 2b, 2t)\) (with \(a\) real) we can visualize \( D \) as the interior of the following solid in \( \mathbb{R}^3 \).

**Proposition 2.2.** Let \( G = SU(2,1) \). Then the map

\[ \Phi : NA \times D \to Cr(X), \quad (na, (Y,Z)) \mapsto na \exp(iY) \exp(iZ) \cdot x_0 \]

is a diffeomorphism.
Proof. All that we have to show is that the map is defined and onto.
To begin with we show that $\Phi$ is defined, i.e., $\operatorname{Im} \Phi \subset \operatorname{Cr}(X)$. Set $n_{a,b} := \exp(iZ_{a,b})$. Let $M = Z_K(\Lambda)$. By $M$-invariance it is no loss of generality to assume that $a$ is real. Then
\[
n_{a,b} = \begin{pmatrix}
1 - b + a^2/2 & ia & b - a^2/2 \\
-ia & 1 & ia \\
-b + a^2/2 & ia & 1 + b - a^2/2
\end{pmatrix}.
\]

We have to show that:
\[
a_{i\phi}n_{a,b}(0) \in X \quad \text{and} \quad \tau(a_{i\phi}n_{a,b})(0) \in X,
\]
for all parameters $(\phi, a, b) \in D$. Note that $\tau(a_{i\phi}) = a_{i\phi}$ and $\tau(n_{a,b}) = n_{a,-b}$. Now
\[
n_{a,\phi}(0) = \frac{1}{1 + b - a^2/2}(b - a^2/2, ia).
\]
Note that $n_{a,b}(0) \in X$ if and only if
\[
(b - a^2/2)^2 + a^2 < (1 + b - a^2/2)^2
\]
or
\[
-2b + 2a^2 < 1.
\]
Combined with $n_{a,-\phi}(0) \in X$ we arrive at $2|b| + 2a^2 < 1$, which is the defining condition of $\Lambda$.

We move on and apply $a_{i\phi}$ to $n_{a,\pm b}(0)$, and obtain that
\[
a_{i\phi}n_{a,\pm b}(0) = \frac{(\cos \phi \frac{\pm b - a^2/2}{1 \pm b - a^2/2} + i \sin \phi, \frac{ia}{1 \pm b - a^2/2})}{\cos \phi + i \sin \phi \frac{\pm b - a^2/2}{1 \pm b - a^2/2}}.
\]
Hence $a_{i\phi}n_{a,\pm b}(0) \in X$ if and only if
\[
\cos^2 \phi + \sin^2 \phi \frac{(\pm b - a^2/2)^2}{(1 \pm b - a^2/2)^2} > \cos^2 \phi \frac{(\pm b - a^2/2)^2}{(1 \pm b - a^2/2)^2} + \sin^2 \phi + \frac{a^2}{(1 \pm b - a^2/2)^2}
\]
or, equivalently, after clearing denominators,
\[
(1 \pm b - a^2/2)^2 \cos^2 \phi + (\pm b - a^2/2)^2 \sin^2 \phi > (\pm b - a^2/2)^2 \cos^2 \phi + (1 \pm b - a^2/2)^2 \sin^2 \phi + a^2.
\]
Simplifying further we arrive at
\[
\cos^2 \phi + 2(\pm b - a^2/2) \cos^2 \phi > \sin^2 \phi + 2(\pm b - a^2/2) \sin^2 \phi + a^2
\]
or, equivalently,
\[
(1 \pm 2b - 2a^2) \cos(2\phi) > (1 - \cos 2\phi)a^2.
\]
However, this is the defining condition for $D$.

To see that the map is onto we observe that $\operatorname{Cr}(X) \subset N_{\mathbb{C}} A_{\mathbb{C}} \cdot x_0$. Hence there exists a domain $D' \subset a + n$ such that
\[
\operatorname{Cr}(X) = NA \cdot \{\exp(iY) \exp(iZ) \mid (Y, Z) \in D'\}.
\]
If $D'$ is strictly larger than $D$, then $D'$ would contain a boundary point of $D$. Our computations show that this is not possible, and the proof of the proposition is concluded. \qed
3. THE CROWN FOR HOMOGENEOUS HARMONIC SPACES

Let $S$ be a simply connected noncompact homogeneous harmonic space. According to [7], Corollary 1.2, there are the following possibilities for $S$:

(i) $S = \mathbb{R}^n$.

(ii) $S$ is the $AN$-part of a noncompact simple Lie group $G$ of real rank one.

(iii) $S = A \ltimes N$ with $N$ a nilpotent group of Heisenberg-type and $A \simeq \mathbb{R}$ acting on $N$ by graduation preserving scalings.

The case of $S = \mathbb{R}^n$ we will not consider; groups under (ii) are referred to as symmetric solvable harmonic groups. We mention that all spaces in (ii), except for those associated to $G = \text{SO}_o(1, n)$, are of the type in (iii). Most issues of the Lorentz groups $G = \text{SO}_o(1, n)$ readily reduce to $\text{SO}_o(1, 2) \simeq \text{PSl}(2, \mathbb{R})$, where comprehensive treatments are available. In fact, for the real hyperbolic spaces $X = H^n(\mathbb{R}) = \text{SO}_o(1, n)/\text{SO}(n)$ we obtain the following result, analogous to Proposition 3.1.

**Proposition 3.1.** Let $G = \text{SO}_o(1, n)$ $(n \geq 2)$. Then the map

$$NA \times \Omega \times \Lambda \to \text{Cr}(X), \quad (na, H, Y) \mapsto na \exp(iH) \exp(iY) \cdot x_0$$

is a diffeomorphism.

We will now focus on type (iii). In the sequel we recall some basic facts about $H$-type groups and their solvable harmonic extensions. We refer to [14] for a more comprehensive treatment and references. After that we introduce the crown domain for such harmonic extensions.

3.1. $H$-type Lie algebras and groups. Let $\mathfrak{n}$ be a real nilpotent Lie algebra of step two (that is, $[\mathfrak{n}, \mathfrak{n}] \neq \{0\}$ and $[\mathfrak{n}, [\mathfrak{n}, \mathfrak{n}]] = \{0\}$), equipped with an inner product $\langle \cdot, \cdot \rangle$ and associated norm $|\cdot|$. Let $\mathfrak{j}$ be the center of $\mathfrak{n}$ and $\mathfrak{v}$ its orthogonal complement in $\mathfrak{n}$. Then

$$\mathfrak{n} = \mathfrak{v} \oplus \mathfrak{j}, \quad [\mathfrak{v}, \mathfrak{j}] = 0, \quad [\mathfrak{n}, [\mathfrak{n}, \mathfrak{n}]] = [\mathfrak{v}, \mathfrak{v}] \subset \mathfrak{j}.$$

For $Z \in \mathfrak{j}$ let $J_Z : \mathfrak{v} \to \mathfrak{v}$ be the linear map defined by

$$\langle J_Z V, V' \rangle = \langle Z, [V, V'] \rangle, \quad \forall V, V' \in \mathfrak{v}.$$

Then $\mathfrak{n}$ is called a *Heisenberg-type* algebra (or $H$-type algebra, for short) if

$$J_Z^2 = -|Z|^2 \text{id}_{\mathfrak{v}} \quad (Z \in \mathfrak{j}).$$

A connected and simply connected Lie group $N$ is called an $H$-type group if its Lie algebra $\mathfrak{n} = \text{Lie}(N)$ is an $H$-type algebra; see [9].

We let $p = \dim \mathfrak{v}$, $q = \dim \mathfrak{j} (\geq 1)$. Condition (3.1) implies that $p$ is even and $[\mathfrak{v}, \mathfrak{v}] = \mathfrak{j}$.

Moreover, (3.1) implies that the map $Z \to J_Z$ extends to a representation of the real Clifford algebra $\text{Cl}(\mathfrak{j}) \cong \text{Cl}_q$ on $\mathfrak{v}$. This procedure can be reversed and yields a general method for constructing $H$-type algebras.

Since $\mathfrak{n}$ is nilpotent, the exponential map $\exp : \mathfrak{n} \to N$ is a diffeomorphism. The Campbell-Hausdorff formula implies the following product law in $N$:

$$\exp X \cdot \exp X' = \exp \left( X + X' + \frac{1}{2} [X, X'] \right), \quad \forall X, X' \in \mathfrak{n}.$$

This is sometimes written as

$$(V, Z) \cdot (V', Z') = (V + V', Z + Z' + \frac{1}{2} [V, V']),$$
using the exponential chart to parametrize the elements \( n = \exp(V + Z) \) by the couples \((V, Z) \in v \oplus z = n\).

3.1.1. Reduction theory. We conclude this section with reduction theory for \( H \)-type Lie algebras to Heisenberg algebras.

Let \( z_1 = \mathbb{R} z_1 \) be a one-dimensional subspace of \( z \) and \( z_1^\perp \) be its orthogonal complement in \( z \). We assume that \(|z_1| = 1\) and set \( J_1 := J z_1 \). We form the quotient algebra

\[ n_1 := n/z_1^\perp \]

and record that \( n_1 \) is two-step nilpotent. Let \( p_1 : z \rightarrow z_1 \) be the orthogonal projection. If we identify \( n_1 \) with the vector space \( v \oplus z_1 \) via the linear map

\[ n_1 \rightarrow v \oplus z_1, \quad (V, Z) + z_1^\perp \mapsto (V, p_1(Z)) , \]

then the bracket in \( n_1 \) becomes in the new coordinates

\[ [(V, Z_1), (V', Z_1)] = (0, [V, V'] Z_1) , \]

where \( V, V' \in v \). Since \([Z_1, [V, V']]) = (J_1 V, V')\), we see that \( J_1 \) determines a Lie algebra automorphism of \( n_1 \) and thus \( n_1 \) is isomorphic to the \( p + 1 \)-dimensional Heisenberg algebra.

3.2. Harmonic solvable extensions of \( H \)-type groups. Let \( n \) be an \( H \)-type algebra with associated \( H \)-type group \( N \). Let \( a \) be a one-dimensional Lie algebra with an inner product. Write \( a = \mathbb{R} H \), where \( H \) is a unit vector in \( a \). Let \( A = \exp a \) be a one-dimensional Lie group with Lie algebra \( a \) and isomorphic to \( \mathbb{R}^+ \) (the multiplicative group of positive real numbers). Let the elements \( a_t = \exp(tH) \in A \) act on \( N \) by the dilations \( (V, Z) \rightarrow (e^{t/2V}, e^tZ) \) for \( t \in \mathbb{R} \), and let \( S \) be the associated semi-direct product of \( N \) and \( A \):

\[ S = NA = N \rtimes A. \]

The action of \( A \) on \( N \) becomes the inner automorphism

\[ a_t \exp(V + Z)a_t^{-1} = \exp \left( e^{t/2} V + e^t Z \right) , \]

and the product in \( S \) is given by

\[ \exp(V + Z)a_t \exp(V' + Z')a_{t'} = \exp(V + Z)\exp(e^{t/2}V' + e^t Z')a_{t + t'} . \]

\( S \) is a connected and simply connected Lie group with Lie algebra

\[ s = n \oplus a = v \oplus z \oplus a \]

and Lie bracket defined by linearity and the requirement that

\[ [H, V] = \frac{1}{2} V, \quad [H, Z] = Z, \quad \forall V \in v, \forall Z \in z. \]

The map \((V, Z, tH) \rightarrow \exp(V + Z)\exp(tH)\) is a diffeomorphism of \( s \) onto \( S \). If we parametrize the elements \( na = \exp(V + Z)\exp(tH) \in NA \) by the triples \((V, Z, t) \in v \times z \times \mathbb{R} \), then the product law reads

\[ (V, Z, t) \cdot (V', Z', t') = \left( V + e^{t/2} V', Z + e^t Z' + \frac{1}{2} e^{t/2} [V, V'], t + t' \right) . \]

for all \( V, V' \in v, Z, Z' \in z, t, t' \in \mathbb{R} \). For \( n = (V, Z, 0) \in N \) and \( a_t = (0, 0, t) \in A \) we consistently get \( na_t = (V, Z, t) \).
We extend the inner products on $\mathfrak{n}$ and $\mathfrak{a}$ to an inner product $\langle \cdot, \cdot \rangle$ on $\mathfrak{s}$ by linearity and the requirement that $\mathfrak{n}$ be orthogonal to $\mathfrak{a}$. The left-invariant Riemannian metric on $S$ defined by this inner product turns $S$ into a harmonic solvable group $S$.

### 3.3. The complexification and the crown.

Let $N_C$ be the simply connected Lie group with Lie algebra $\mathfrak{n}_C$ and set $A_C = \mathbb{C}^*$. Then $A_C$ acts on $N_C$ by $t \cdot (V, Z) := (tV, t^2Z)$ for $t \in \mathbb{C}^*$ and $(V, Z) \in N_C$.

We define a complexification $S_C$ of $S$ by

$$S_C = N_C \times A_C.$$  

We identify the Lie algebra $\mathfrak{a}$ with $\mathbb{R}$ by sending $H \mapsto 1/2$. For $z \in \mathbb{C}$ we often set $a_z := \exp(zH)$ and note that $a_z$ corresponds to $e^{z/2} \in \mathbb{C}^*$. In particular,

$$\{ z \in \mathbb{C} : \exp(zH) = e \} = 4\pi i \mathbb{Z}.$$  

It follows that the exponential map $\exp : \mathfrak{a}_C \to A_C$ is certainly injective if restricted to $\mathfrak{a} + iH(-2\pi, 2\pi]$.

Motivated by our discussion of $SU(2, 1)$ and the discussed $SU(n, 1)$-reduction, we define the following sets for a more general harmonic $AN$-group:

$$\Omega = \{ tH \in \mathfrak{a} : |t| < \frac{\pi}{2} \},$$

$$\Lambda = \{ (V, Z) \in \mathfrak{n} : \frac{1}{2}|V|^2 + |Z| < 1 \},$$

$$D = \{ (V, Z, t) \in \mathfrak{s} : \cos t(1 - \frac{1}{2}|V|^2 - |Z|) > \frac{1}{4}(1 - \cos t)|V|^2 \},$$

$$D = \{ \exp(itH) \exp(iV + iZ) : (V, Z, t) \in D \} \subset S_C.$$  

Here as usual $\{ \cdot \}_0$ denotes the connected component of $\{ \cdot \}$ containing 0, and we write $(V, Z, t)$ for the element $V + Z + tH$ of $\mathfrak{s}$.

**Definition 3.2.** The complex crown of $S$ will be defined as the following subset of $S_C$:

$$Cr(S) = NAD \subset NA \exp(i\Omega) \exp(i\Lambda) \subset S_C.$$  

It is easy to see that $Cr(S)$ is open and simply connected in $S_C$.

We conclude with the proof of the mixed model of the crown for rank one symmetric spaces. In this case we let $S = AN$ be the solvable part of the rank one group $G = NAK$. Note that $F := A_C \cap K_C$ is isomorphic to $\mathbb{Z}_2$ and that there is an $S_C$-equivariant embedding $S_C/F \to X_C$. As $\exp(2i\Omega) \cap F = \{ e \}$, we thus arrive at an $S$-equivariant embedding $Cr(S) \hookrightarrow X_C$.

**Theorem 3.3.** Let $X = G/K$ be a noncompact Riemannian symmetric space of rank one, $X \neq H^n(\mathbb{R})$. Let $S = NA$, and let $Cr(S)$ be embedded in $X_C$ by $z \mapsto z \cdot x_0$. Then

$$Cr(X) = Cr(S).$$

**Proof.** We first show that $Cr(S) \subset Cr(X)$. We have to show that $\exp(itH)\exp(iY) \cdot x_0 \in Cr(X)$ for all $(Y, t) \in D$. Let $M = Z_K(A)$ and let $S_\mathfrak{s}, S_\mathfrak{z}$ denote the unit spheres in $\mathfrak{s}$ and $\mathfrak{z}$. Since the group $Ad(M)$ acts transitively on $S_\mathfrak{s} \times S_\mathfrak{z}$ (see, e.g., [3], Theorem 6.2, for a simple proof within the framework of $H$-type groups), the assertion is reduced to $G = SU(2, 1)$, where it was shown in Proposition 22 above.

For the converse inclusion let $X_1 = G_1/K_1 \subset X = G/K$ be a subdomain with $K_1 \subset K$ and $G_1 = \Omega_1 = G$. We claim that $\partial Cr(X_1) \subset \partial Cr(X)$. In fact, if $z \in \partial Cr(X_1)$, then Lemma 2.3 (ii) in [13] shows that $z$ is the limit of a sequence...
In order to conclude the proof of the theorem, it is enough to show that the elements which are in the boundary of \( D \) do not lie in \( \text{Cr}(X) \), i.e.,
\[
\{ \exp(itH) \exp(iV+iZ) : (V,Z,t) \in \partial D \} \cap \text{Cr}(X) = \emptyset.
\]
This again reduces to \( G = \text{SU}(2,1) \) and thus follows from \( \partial \text{Cr}(X_1) \subset \partial \text{Cr}(X) \).

\[ \square \]

4. Geometric analysis

Let \( S \) be a simply connected noncompact homogeneous harmonic space, \( S \neq \mathbb{R}^n \). In this section we will show that the eigenfunctions of the Laplace-Beltrami operator on \( S \) extend holomorphically to \( \text{Cr}(S) \) and that \( \text{Cr}(S) \) is maximal with respect to this property.

4.1. Holomorphic extension of eigenfunctions. For \( z \in D \) we consider the following totally real embedding of \( S \) into \( \text{Cr}(S) \):
\[
S \hookrightarrow \text{Cr}(S), \quad s \mapsto sz.
\]
Now let \( \mathcal{L} \) be the Laplace-Beltrami operator on \( S \), explicitly given by (see [14])
\[
\mathcal{L} := \sum_{j=1}^{p} V_j^2 + \sum_{i=1}^{q} Z_i^2 + H^2 - 2\rho H,
\]
where \( 2\rho = (p/2) + q \) and the \( (V_j)_j \) and \( (Z_i)_i \) form an orthonormal basis of \( \mathfrak{v} \) and \( \mathfrak{j} \), respectively. Here we consider the elements \( X \in \mathfrak{s} \) as left-invariant vector fields on \( S \). Hence it is clear that \( \mathcal{L} \) extends to a left \( S_C \)-invariant holomorphic differential operator on \( S_C \), which we denote by \( \mathcal{L}_C \). Now if \( M \subset S_C \) is a totally real analytic submanifold, then we can restrict \( \mathcal{L}_C \) to \( M \), in symbols \( \mathcal{L}_M \), in the following way: if \( f \) is a real analytic function near \( m \in M \) and \( f_C \) is a holomorphic extension of \( f \) in a complex neighborhood of \( m \) in \( S_C \), then set
\[
(\mathcal{L}_M f)(m) := (\mathcal{L}_C f_C)(m).
\]
Then:

**Proposition 4.1.** For all \( z \in D \) the restriction \( \mathcal{L}_{S_z} \) is elliptic.

**Proof.** To illustrate what is going on we first give a proof for those \( S \) related to \( G = \text{SL}(2,\mathbb{R}) \). We consider this as the degenerate case where \( \mathfrak{v} = \{0\} \) so that \( \text{ad}(H) \) acts on \( \mathfrak{n} = \mathfrak{j} = \mathbb{R}Z \) as the identity map (see [3], section 3(d)). Here
\[
H = \begin{pmatrix} 1/2 & 0 \\ 0 & -1/2 \end{pmatrix}, \quad Z = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}.
\]
The set \( D \) degenerates to the product
\[
\mathcal{D} = \Omega 
\times \Lambda = \{ tH : |t| < \frac{\pi}{2} \} \times \{ xZ : |x| < 1 \},
\]
and \( D = \exp(it\Omega) \exp(i\Lambda) \), in agreement with Proposition 2.1. The Laplace-Beltrami operator on \( S \) becomes \( \mathcal{L} = Z^2 + H^2 - H \). Let \( z = \exp(itH) \exp(ixZ) \in D \). Using
\([H, Z] = Z\) we get

\[
\text{Ad}(z)H = H - ie^{it}xZ,
\]
\[
\text{Ad}(z)Z = e^{it}Z.
\]

It follows that the leading symbol, or principal part, of \(L_{Sz}\) is given by

\[
[L_{Sz}]_{\text{prin}} = (H - ie^{it}xZ)^2 + e^{2it}Z^2.
\]

Let us verify that \(L_{Sz}\) is elliptic. The associated quadratic form is given by the matrix

\[
L(z) := \begin{pmatrix}
1 & -ixe^{it} \\
-ixe^{it} & e^{2it}(1 - x^2)
\end{pmatrix}.
\]

We have to show that \(\langle L(z)\xi, \xi \rangle = 0\) has no solution for \(\xi = (\xi_1, \xi_2) \in \mathbb{R}^2 \setminus \{0\}\). We look at

\[
\xi_1^2 - 2ixe^{it}\xi_1\xi_2 + e^{2it}(1 - x^2)\xi_2^2 = 0.
\]

Now \(\xi_2 = 0\) is readily excluded, and we remain with the quadric

\[
\xi^2 - 2ixe^{it}\xi + e^{2it}(1 - x^2) = 0,
\]

whose solutions are

\[
\lambda_{1, 2} = ixe^{it} \pm \sqrt{-x^2e^{2it} - (1 - x^2)e^{2it}}.
\]

These are never real in the domain \(-\frac{\pi}{2} < t < \frac{\pi}{2}\) and \(-1 < x < 1\). The same proof works for those \(S\) related to \(\text{SO}(1, n), n \geq 2\).

To put the computation above in a more abstract framework: it is to show here that for \(z \in D\) the operator \(L(z) : \mathfrak{g}_C \to \mathfrak{g}_C\) defined by

\[
(4.1) \quad L(z) := \text{Ad}(z)^t \text{Ad}(z)
\]

is elliptic in the sense that \(\langle L(z)\xi, \xi \rangle = 0\) for \(\xi \in \mathfrak{s}\) implies \(\xi = 0\).

Thus, for the sequel we assume that \(\mathfrak{n}\) is \(H\)-type, i.e., \(\mathfrak{v}\) and \(\mathfrak{z}\) are \(\neq \{0\}\). We will reduce to the case where \(N\) is a Heisenberg group, i.e., \(S\) is related to \(\text{SU}(1, n)\). We use the already introduced technique of reduction to Heisenberg groups. Therefore, let \(Z_1 \in \mathfrak{z}\) be a normalized element and \(n_1 = n/\mathfrak{z}_1^1\) be as before. We let \(S_1\) be the harmonic group associated to \(N_1\) and note that there is a natural group homomorphism \(S \to S_1\) which extends to a holomorphic map \(S_C \to (S_1)_C\) which maps \(\text{Cr}(S)\) onto \(\text{Cr}(S_1)\). Now the assertion is true for \(\text{Cr}(S_1)\) in view of [11] (proof of Th. 3.2) and Theorem [3, 3]. Let \(M\) be the group of automorphisms of \(S\) preserving the inner product on \(\mathfrak{s}\). By [3], Proposition 6.1 and Remark 6.3, the group \(\text{Ad}(M)\) acts transitively on the unit sphere in \(\mathfrak{z}\). Thus the ellipticity of (4.1) is true for \(S\) if it is true for all choices of \(S_1\), and the assertion follows. \(\square\)

As a consequence of this fact, we obtain as in [11] that:

**Theorem 4.2.** Every \(L\)-eigenfunction on \(S\) extends to a holomorphic function on \(\text{Cr}(S)\).

**Proof** (analogous to the proof of Th. 3.2 of [11]). As \(L\) is elliptic, the regularity theorem for elliptic differential operators implies that all eigenfunctions \(f\) are analytic and extend holomorphically on a neighborhood of \(1\) in \(S_C\). This neighborhood can be chosen independently of \(f\).
Let $0 \leq t \leq 1$ and define $D_t := tD$ and correspondingly $D_t$. It follows that all eigenfunctions $f$ extend holomorphically to a common domain of the form $UD_t \subset S_C$ for some $0 < t \leq 1$ and some open neighborhood $U$ of 1 in $S$. As $L$ is $S$-invariant we can replace $f$ by any left $S$-translate and conclude that $f$ extends to $SD_t \subset S_C$.

If $t = 1$, we are finished. Otherwise, let $t$ be such that all eigenfunctions $f$ extend to $SD_t$, but for each $t < t' \leq 1$ some eigenfunction does not extend to $SD_{t'}$. Let $(Y, r) \in \partial D_t$ and let $z = \exp(iH) \exp(iY)$. By our previous proposition, $L_{Sz}$ is elliptic. Now it comes down to choosing appropriate local coordinates to see that $f$ extends holomorphically on a complex cone based at $z$. The condition (9.4.16) in [8], Cor. 9.4.9, is verified so that this corollary applies. We conclude that there exists an open neighborhood of $z$ on which all eigenfunctions $f$ are holomorphic.

By compactness of $\partial D_t$ we then find $t' > t$ and an open neighborhood $U$ of 1 in $S$, both independent of $f$, such that $f$ extends holomorphically to $UD_{t'}$. As before we obtain that $f$ extends to $SD_{t'}$. As this is valid for all $f$ a contradiction is reached and the theorem follows.

\begin{proof}

4.2. Maximality of $\text{Cr}(S)$. We begin with a collection of some facts about Poisson kernels on $S$. Let us denote by $\theta : S \to S$ the geodesic symmetry, centered at the identity. Every $z \in S_C$ can be uniquely written as $z = n(z)a(z)$ with $n \in N_C$ and $a \in A_C$. As $\text{Cr}(S)$ is simply connected, we obtain for every $\lambda \in a_C^*$ a holomorphic map

$$a^\lambda : \text{Cr}(S) \to \mathbb{C}, \ z \mapsto e^{\lambda \log a(z)}.$$ 

The function $P_\lambda := a^{\nu - i\lambda} \circ \theta$ on $S$ is referred to as the Poisson kernel on $S$ with parameter $\lambda$. We note that both $\lambda^P$ and $P_\lambda$ are $L$-eigenfunctions [4, 1].

For $\lambda \in a_C^*$, we define the spherical function with parameter $\lambda$ by

$$\phi_\lambda(s) := b \int_N P_\lambda(ns)P_{-\lambda}(n) \, dn \quad (s \in S),$$

where $b = 2^{g - 1} \Gamma\left(\frac{g + 1}{2}\right)/\pi^{\frac{g + 1}{2}}$ is a constant such that $\phi_\lambda(\epsilon) = 1$.

Let us denote by $\mathcal{X} \subset a_C^*$ the parameter set for nontrivial positive definite spherical functions on $S$ and note that $a^* \subset \mathcal{X}$.

**Theorem 4.3.** The crown domain $\text{Cr}(S)$ is the unique largest $S$-invariant domain in $S_C$ containing $S$ with the property that all $L$-eigenfunctions extend holomorphically to $\text{Cr}(S)$.

**Proof.** Let us first discuss the case of symmetric $S$, i.e. $S \simeq X = G/K$ and $\text{Cr}(S) = \text{Cr}(X)$. Fix $\lambda \in \mathcal{X}$. In this case it was shown in Section 5 of [12] (with corrigendum in [10], Remark 4.8) that $\text{Cr}(X)$ is the unique largest $G$-invariant domain in $X_C$ containing $X$ to which $\phi_\lambda$ extends holomorphically. We will now adapt this method to the $S$-invariant situation.

Let $z \in \partial \text{Cr}(S)$. Recall the elliptic boundary of $\text{Cr}(X)$ in $X_C$, $\partial_{\text{ell}} \text{Cr}(X) = G \exp(i\partial \Omega) \cdot x_0 \subset \partial \text{Cr}(X)$. Let us first assume that $z \in \partial \text{Cr}(S) \cap \partial_{\text{ell}} \text{Cr}(X)$. Assume that $\phi_\lambda$ extends holomorphically to an open neighborhood $U \subset S_C$ of $z$. We find $r > 1$ and $z_0 \in \exp(i\partial \Omega)$ and $g \in G$ such that $gz_0 \in U$.

Set $\psi_\lambda := \phi_\lambda \circ g^{-1}$. Then $\psi_\lambda$ is an $L$-eigenfunction. Now it was shown in [12] (Lemma 5.3 and Th. 5.4 with proof) that there exists an $s \in S$ and a sequence $(s_n)_{n \in \mathbb{N}} \subset S$ with $\lim_{n \to \infty} s_n = s \in S$ such that

$$0 \leq \phi_\lambda(s_n z_0) \nearrow \infty.$$
Now Lemma 5.3 in [12] readily modifies and allows us to replace the sequence $(s_n)_{n \in \mathbb{N}}$ by a sequence $(g^{-1}u_ng)_{n \in \mathbb{N}}$ with $u_n \in S$ converging to $u \in S$. Hence we get that
\begin{equation}
0 \leq \psi_\lambda(u_nz) \nearrow \infty,
\end{equation}
a contradiction. If $z$ is not in the elliptic boundary, then we argue as in [10], Rem. 4.8, and reach the same conclusion.

For nonsymmetric $S$ we apply SU(2,1)-reduction (see [2]). If $z \in \text{Cr}(S)$, then we can put $z \in \text{Cr}(S_1)$ with $\text{Cr}(S_1)$ an SU(2,1)-crown contained in $\text{Cr}(S)$. Let $\mathcal{X}_1$ be the set of equivalence classes of nontrivial positive definite spherical functions on $S_1$ and note that $\mathcal{X}_1 = a^\ast \Pi (e^{c\rho_1}, e^{c\rho_1})$ for some $c > 0$. Disintegration theory of unitary representations yields a positive Radon measure $\mu$ on $\mathcal{X}_1$ such that
\[ \phi_\lambda |_{S_1} = \int_{\mathcal{X}_1 \cup \{1\}} \phi_\lambda^1 \, d\mu(\sigma). \]
Here $\phi_\lambda^1$ stands for the spherical function on $S_1$ with parameter $\sigma$. If we can exclude the case that $\text{supp} \mu = \{1\}$, then the assertion follows with (4.2) as before.

Finally $\text{supp} \mu = \{1\}$ cannot happen, as $\phi_\lambda|_A$ is not constant and $A \subset S_1$. \hfill \Box

**Corollary 4.4.** The geodesic symmetry extends to a holomorphic involutive map $\theta : \text{Cr}(S) \to \text{Cr}(S)$.

**Proof.** For all $\lambda \in a^\circ_C$ the Poisson kernel $P_\lambda = a^{\rho - i\lambda} \circ \theta$ extends to a holomorphic function on $\text{Cr}(S)$. Thus the map $\theta$ must extend to a holomorphic involutive map
\[ \theta : \text{Cr}(S) \to S_C. \]
To see that $\theta(\text{Cr}(S)) = \text{Cr}(S)$, we observe that $\theta(\text{Cr}(S))$ is an open connected, $S$-invariant neighborhood of $S$ in $S_C$ ($\theta$ being holomorphic and involutive). Suppose this neighborhood is not contained in $\text{Cr}(S)$. Then there exists a boundary point $z \in \partial \text{Cr}(S)$ and a $q \in \text{Cr}(S)$ such that $z = \theta(q)$. However, then
\[ P_\lambda(z) = a^{\rho - i\lambda}(q). \]
Now the right-hand side in this formula is well defined $\forall \lambda \in a^\circ_C$, whereas the left-hand side blows up for some $\lambda \in a^\circ_C$ (if it did not, then $\phi_\lambda$ for some $\lambda \in \mathcal{X}$ would extend holomorphically to an $S$-invariant domain strictly containing $\text{Cr}(S)$). It follows that $\theta(\text{Cr}(S)) \subseteq \text{Cr}(S)$. The opposite inclusion is clear from the involutivity of $\theta$. \hfill \Box
