

SIERPIŃSKI AND CARMICHAEL NUMBERS

WILLIAM BANKS, CARRIE FINCH, FLORIAN LUCA, CARL POMERANCE,
AND PANTELIMON STĂNICĂ

ABSTRACT. We establish several related results on Carmichael, Sierpiński and Riesel numbers. First, we prove that almost all odd natural numbers k have the property that $2^n k + 1$ is not a Carmichael number for any $n \in \mathbb{N}$; this implies the existence of a set \mathcal{K} of positive lower density such that for any $k \in \mathcal{K}$ the number $2^n k + 1$ is neither prime nor Carmichael for every $n \in \mathbb{N}$. Next, using a recent result of Matomäki and Wright, we show that there are $\gg x^{1/5}$ Carmichael numbers up to x that are also Sierpiński and Riesel. Finally, we show that if $2^n k + 1$ is Lehmer, then $n \leq 150\omega(k)^2 \log k$, where $\omega(k)$ is the number of distinct primes dividing k .

1. INTRODUCTION

In 1960, Sierpiński [25] showed that there are infinitely many odd natural numbers k with the property that $2^n k + 1$ is composite for every natural number n ; such an integer k is called a *Sierpiński number* in honor of his work. Two years later, J. Selfridge (unpublished) showed that 78557 is a Sierpiński number, and this is still the smallest known example.¹

Every currently known Sierpiński number k possesses at least one *covering set* \mathcal{P} , which is a finite set of prime numbers with the property that $2^n k + 1$ is divisible by some prime in \mathcal{P} for every $n \in \mathbb{N}$. For example, Selfridge showed that 78557 is Sierpiński by proving that every number of the form $2^n \cdot 78557 + 1$ is divisible by a prime in $\mathcal{P} := \{3, 5, 7, 13, 19, 37, 73\}$. When a covering set is used to show that a given number is Sierpiński, every natural number in a certain arithmetic progression (determined by the covering set) must also be Sierpiński; in particular, the set of Sierpiński numbers has a positive lower density.

If N is a prime number, *Fermat's little theorem* asserts that

$$(1) \quad a^N \equiv a \pmod{N} \quad \text{for all } a \in \mathbb{Z}.$$

Around 1910, Carmichael [9, 10] initiated the study of composite numbers N with the same property; these are now known as *Carmichael numbers*. In 1994, Alford, Granville and Pomerance [1] proved the existence of infinitely many Carmichael numbers. Since prime numbers and Carmichael numbers share the property (1), it is natural to ask whether certain results for primes can also be established for Carmichael numbers; see, for example, [2, 3, 5, 14, 20, 29] and the references contained therein.

Received by the editors October 1, 2012 and, in revised form, January 16, 2013.

2010 *Mathematics Subject Classification*. Primary 11J81, 11N25; Secondary 11A07, 11A51.

¹At present, there are only six smaller numbers that *might* have the Sierpiński property: 10223, 21181, 22699, 24737, 55459, 67607; see <http://www.seventeenorbust.com> for the most up-to-date information.

Our work in this paper originated with the question as to whether there exist Sierpiński numbers k such that $2^n k + 1$ is *not* a Carmichael number for any $n \in \mathbb{N}$. Since there are many Sierpiński numbers and only a few Carmichael numbers, it is natural to expect there are many such k . However, because the parameter n can take any positive integer value, the problem is both difficult and interesting. Later on, we dropped the condition that k be Sierpiński and began to study odd numbers k for which $2^n k + 1$ is never a Carmichael number. Our main result is the following theorem.

Theorem 1. *Almost all odd natural numbers k have the property that $2^n k + 1$ is not a Carmichael number for any $n \in \mathbb{N}$.*

This is proved in §2. Our proof uses results and methods from a recent paper of Cilleruelo, Luca and Pizarro-Madariaga [11], where it is shown that the bound

$$(2) \quad n \leq 2^{2000000} \tau(k)^2 \omega(k) (\log k)^2$$

holds for every Carmichael number $2^n k + 1$. Here, $\tau(k)$ is the number of positive integer divisors of k , and $\omega(k)$ is the number of distinct prime factors of k . To give some perspective on this result, let $v_2(\cdot)$ be the standard 2-adic valuation, so that $2^{-v_2(m)}m$ is the odd part of any natural number m . Theorem 1 implies that the set

$$\{k = 2^{-v_2(n-1)}(n-1) : n \text{ is a Carmichael number}\}$$

has asymptotic density zero.² By comparison, Erdős and Odlyzko [15] have shown that the set

$$\{k = 2^{-v_2(p-1)}(p-1) : p \text{ is a prime number}\}$$

has a positive lower density.

Since the collection of Sierpiński numbers has a positive lower density, the following corollary is an immediate consequence of Theorem 1.

Corollary 1. *There exists a set $\mathcal{K} \subseteq \mathbb{N}$ of positive lower density such that for any fixed $k \in \mathcal{K}$, the number $2^n k + 1$ is neither prime nor Carmichael for each $n \in \mathbb{N}$.*

Riesel numbers have a similar definition to that of Sierpiński numbers. An odd natural number k is called a *Riesel number* if $2^n k - 1$ is composite for all $n \in \mathbb{N}$. Such numbers were first investigated in 1956 by Riesel [24]. At present, the smallest known example is 509203.³ It is known that there are infinitely many natural numbers that are both Sierpiński and Riesel. Using recent results of Matomäki [20] and Wright [29] coupled with an extensive computer search, we prove the following result in §3.

Theorem 2. *Infinitely many natural numbers are simultaneously Sierpiński, Riesel, and Carmichael. In fact, the number of them up to x is $\gg x^{1/5}$ for all sufficiently large x .*

Let $\varphi(\cdot)$ be the *Euler function*, which is defined by $\varphi(n) := n \prod_{p|n} (1 - p^{-1})$ for all $n \in \mathbb{N}$; in particular, one has $\varphi(p) = p - 1$ for every prime p . In 1932, Lehmer [19] asked whether there are any composite numbers n such that $\varphi(n) \mid n - 1$, and the answer to this question is still unknown. We say that n is a *Lehmer number* if

²In [11] it is shown that 27 is the smallest number in this set.

³As of this writing, there are 55 candidates smaller than 509203 to consider; see <http://www.prothsearch.net/rieselprob.html> for the most recent information.

n is composite and $\varphi(n) \mid n - 1$. It is easy to see that every Lehmer number is Carmichael, but there are infinitely many Carmichael numbers which are not Lehmer (see [4]). We prove the following result in §4.

Theorem 3. *Let k be an odd natural number. If $2^n k + 1$ is Lehmer, then $n \leq 150 \omega(k)^2 \log k$.*

Remark. The situation for Lehmer numbers of the form $2^n k - 1$ is trivial. Indeed, when $N := 2^n k - 1$ is Lehmer, then $\varphi(N) \mid N - 1 = 2(2^{n-1} k - 1)$. For $n \geq 2$ this implies that $4 \nmid \varphi(N)$, which is impossible since N is odd, squarefree and composite. Therefore, n must be 1.

Throughout the paper, we use $\log_k x$ to denote the k -th iterate of the function $\log x := \max\{\ln x, 1\}$, where $\ln x$ is the natural logarithm. We use the notation O, o, \ll, \gg with their customary meanings. Any constant or function implied by one of these symbols is absolute unless otherwise indicated.

2. PROOF OF THEOREM 1

2.1. Preliminary estimates. Let x be a large real parameter, and put

$$\mathcal{C}(x) := \{\text{odd } k \in (x/2, x] : 2^n k + 1 \text{ is Carmichael for some } n\}.$$

If $\mathcal{S}(x) \subseteq \mathcal{C}(x)$ for all large x , we say that $\mathcal{S}(x)$ is *negligible* if $|\mathcal{S}(x)| = o(x)$ as $x \rightarrow \infty$. Below, we construct a sequence $\mathcal{C}_1(x), \mathcal{C}_2(x), \dots$ of negligible subsets of $\mathcal{C}(x)$, and for each $j \geq 1$ we denote

$$\mathcal{C}_j^*(x) := \mathcal{C}(x) \setminus \bigcup_{i=1}^j \mathcal{C}_i(x).$$

Theorem 1 is the statement that $\mathcal{C}(x)$ is itself negligible; thus, we need to show that $\mathcal{C}_j^*(x)$ is negligible for some j .

Let $\Omega(n)$ be the number of prime factors of n , counted with multiplicity, and put

$$\mathcal{N}_1(x) := \{k \leq x : \Omega(k) > 1.01 \log_2 x\}.$$

Since $\log_2 x$ is the normal order of $\Omega(n)$ over numbers $n \leq x$, it follows that

$$(3) \quad |\mathcal{N}_1(x)| = o(x) \quad (x \rightarrow \infty).$$

In fact, using the Turán-Kubilius inequality (see [27]) one sees that $|\mathcal{N}_1(x)| \ll x/\log_2 x$, and stronger bounds can be deduced from results in the literature (although they are not needed here). Using (3) it follows that

$$\mathcal{C}_1(x) := \mathcal{C}(x) \cap \mathcal{N}_1(x)$$

is negligible.

Next, let $\Omega(z; n)$ denote the number of prime factors $p \leq z$ of n , counted with multiplicity. Set

$$\mathcal{N}_2(x) := \{k \leq x : \Omega(z_1; k) > 2 \log_3 x\} \quad \text{with } z_1 := (\log x)^{10}.$$

Since the normal order of $\Omega(z_1; n)$ over numbers $n \leq x$ is $\log_2 z_1 \sim \log_3 x$, it follows that $|\mathcal{N}_2(x)| = o(x)$ as $x \rightarrow \infty$; therefore,

$$\mathcal{C}_2(x) := \mathcal{C}(x) \cap \mathcal{N}_2(x)$$

is negligible.

In what follows, we denote

$$y_L := x^{1/2-10\varepsilon} \quad \text{and} \quad y_U := x^{1/2+10\varepsilon},$$

where

$$\varepsilon = \varepsilon(x) := \frac{1}{\log_2 x}.$$

According to Tenenbaum [26, Théorème 1] (see also Ford [17, Theorem 1]) there are precisely $x/(\log_2 x)^{\delta+o(1)}$ numbers $k \leq x$ that have a divisor $d \in [y_L, y_U]$, where $\delta := 1 - (1 + \ln \ln 2)/\ln 2$; in particular, the set

$$\mathcal{N}_3(x) := \{k \leq x : k \text{ has a divisor } d \in [y_L, y_U]\}$$

is such that $|\mathcal{N}_3(x)| = o(x)$ as $x \rightarrow \infty$; therefore,

$$\mathcal{C}_3(x) := \mathcal{C}(x) \cap \mathcal{N}_3(x)$$

is negligible.

For each $k \in \mathcal{C}(x)$, let $n_0(k)$ be the least $n \in \mathbb{N}$ for which $2^n k + 1$ is a Carmichael number. For any real $X \geq 1$ let

$$\mathcal{F}(X) := \{k \in \mathcal{C}(x) : n_0(k) \leq X\},$$

and for any subset $\mathcal{Q} \subseteq \mathbb{N}$, let $\mathcal{F}(\mathcal{Q}; X)$ be the set of $k \in \mathcal{F}(X)$ for which there exists $n \leq X$ with the property that $2^n k + 1$ is a Carmichael number divisible by some number $q \in \mathcal{Q}$.

Lemma 1. *If X and \mathcal{Q} are both defined in terms of x , and one has*

$$X \sum_{q \in \mathcal{Q}} q^{-1} = o(1) \quad \text{and} \quad X|\mathcal{Q}| = o(x) \quad (x \rightarrow \infty),$$

then $|\mathcal{F}(\mathcal{Q}; X)| = o(x)$ as $x \rightarrow \infty$.

Proof. For fixed $n \leq X$ and $q \in \mathcal{Q}$, if $2^n k + 1$ is a Carmichael number that is divisible by q , then k lies in the arithmetic progression $-2^{-n} \pmod q$; thus, the number of such $k \leq x$ cannot exceed $x/q + 1$. Summing over all $n \leq X$ and $q \in \mathcal{Q}$ we derive that

$$|\mathcal{F}(\mathcal{Q}; X)| \leq \sum_{\substack{n \leq X \\ q \in \mathcal{Q}}} (x/q + 1) \leq xX \sum_{q \in \mathcal{Q}} q^{-1} + X|\mathcal{Q}| = o(x) \quad (x \rightarrow \infty),$$

as required. □

2.2. Small values of $n_0(k)$. Consider the set

$$\mathcal{C}_4(x) := \mathcal{F}(X_1), \quad \text{where} \quad X_1 := \frac{\log x}{\log_2 x}.$$

According to Pomerance [22] there are $\ll t/L(t)$ Carmichael numbers that do not exceed t , where

$$L(t) := \exp\left(\frac{\log t \log_3 t}{\log_2 t}\right).$$

Since the function $f(k) := 2^{n_0(k)}k + 1$ is one-to-one and maps $\mathcal{C}_4(x)$ into the set of Carmichael numbers not exceeding $2^{X_1}x + 1$, we have

$$|\mathcal{C}_4(x)| \ll \frac{2^{X_1}x}{L(2^{X_1}x)} = \frac{x}{L(x)^{1+o(1)}} = o(x) \quad (x \rightarrow \infty).$$

In other words, $\mathcal{C}_4(x)$ is negligible.

2.3. **Medium values of $n_0(k)$.** Our aim in this subsection is to show that

$$\mathcal{S}(x) := \mathcal{F}(X_2) \setminus \mathcal{F}(X_1) \quad \text{with} \quad X_2 := \exp\left(\frac{\log x}{\log_2 x}\right)$$

is negligible. To do this, we define five more negligible sets $\mathcal{C}_5(x), \dots, \mathcal{C}_9(x)$ and show that $\mathcal{S}(x)$ is contained in $\bigcup_{i=1}^9 \mathcal{C}_i(x)$. We denote

$$\mathcal{S}_j^*(x) := \mathcal{S}(x) \setminus \bigcup_{i=1}^j \mathcal{C}_i(x) \quad (1 \leq j \leq 9).$$

As before, we put

$$z_1 := (\log x)^{10}, \quad y_L := x^{1/2-10\varepsilon}, \quad y_U := x^{1/2+10\varepsilon}, \quad \varepsilon := \frac{1}{\log_2 x}.$$

Note that $X_2 = x^\varepsilon$ with this notation.

Let $N := 2^n k + 1$ be a Carmichael number with $k \in \mathcal{S}_4^*(x)$ and $n \leq X_2$. For any prime p dividing N we have $p - 1 \mid N - 1 = 2^n k$ (the well-known Korselt's criterion); thus, $p = 2^m d + 1$ for some $m \leq n$ and some divisor $d \mid k$. Note that $d \notin [y_L, y_U]$ since $k \notin \mathcal{C}_3(x)$.

Suppose that $d > y_U$. Writing $k = dd_1$ we see that $d_1 \leq x/d < x/y_U = y_L$. Furthermore, $2^{n-m} d_1 = (N - 1)/(p - 1) \equiv 1 \pmod{p}$; that is, $p \mid 2^{n-m} d_1 - 1$. Note that $2^{n-m} d_1 - 1 = (N - p)/(p - 1)$ is nonzero since N is Carmichael, hence composite.

Now let \mathcal{P} be the set of primes of the form $2^m d + 1$ with $m \leq X_2$ and $d \in [y_U, x]$, and let \mathcal{P}_1 be the subset of \mathcal{P} consisting of those primes p that divide at least one Carmichael number $N = 2^n k + 1$ with $k \in \mathcal{S}_4^*(x)$ and $n \leq X_2$. In view of the above discussion we have

$$\prod_{p \in \mathcal{P}_1} p \left| \prod_{\substack{0 \leq \ell \leq X_2 \\ d_1 \leq y_L \\ (\ell, d_1) \neq (0, 1)}} (2^\ell d_1 - 1) \leq \prod_{\substack{0 \leq \ell \leq X_2 \\ d_1 \leq y_L}} e^{X_2} \leq \exp(2X_2^2 y_L). \right.$$

Here, we have used the fact that $2^\ell d_1 - 1 \leq 2^{X_2} y_L \leq e^{X_2}$ holds for $x > x_0$. Since $p \geq y_U \geq x^{1/2}$ for all $p \in \mathcal{P}$, it follows that

$$|\mathcal{P}_1| \leq \frac{\log\left(\prod_{p \in \mathcal{P}_1} p\right)}{\log(x^{1/2})} \leq \frac{4X_2^2 y_L}{\log x} = \frac{4x^{1/2-8\varepsilon}}{\log x}$$

for $x > x_0$; in particular, $X_2 |\mathcal{P}_1| = o(x)$ as $x \rightarrow \infty$. Using this inequality for $|\mathcal{P}_1|$ we also have

$$X_2 \sum_{p \in \mathcal{P}_1} p^{-1} \leq \frac{X_2 |\mathcal{P}_1|}{y_U} \leq \frac{4x^{-17\varepsilon}}{\log x} = o(1) \quad (x \rightarrow \infty).$$

Applying Lemma 1 we see that the set

$$\mathcal{C}_5(x) := \mathcal{S}_4^*(x) \cap \mathcal{F}(\mathcal{P}_1; X_2) = \mathcal{C}_4^*(x) \cap \mathcal{F}(\mathcal{P}_1; X_2)$$

is negligible.

Similarly, let \mathcal{P}_2 be the set of primes of the form $2^m d + 1$ with $m \geq \log x$ and $d \leq y_L$. Clearly, for $x > x_0$ we have the bound

$$(4) \quad |\mathcal{P}_2| \leq \left| \{(m, d) : 1 \leq m \leq X_2, d \leq y_L\} \right| \leq X_2 y_L = x^{1/2-9\varepsilon}.$$

Therefore, $X_2|\mathcal{P}_2| = o(x)$ as $x \rightarrow \infty$. Moreover,

$$X_2 \sum_{p \in \mathcal{P}_2} p^{-1} \leq \frac{X_2|\mathcal{P}_2|}{2^{\log x}} \leq x^{1/2 - \ln 2 - 8\epsilon} = o(1) \quad (x \rightarrow \infty).$$

Applying Lemma 1 we see that the set

$$\mathcal{C}_6(x) := \mathcal{S}_5^*(x) \cap \mathcal{F}(\mathcal{P}_2; X_2) = \mathcal{C}_5^*(x) \cap \mathcal{F}(\mathcal{P}_2; X_2)$$

is negligible.

We now take a moment to observe that for every $k \in \mathcal{S}_6^*(x)$ one has

$$n_0(k) \leq X_3 \quad \text{with} \quad X_3 := (\log x)^3.$$

Indeed, let $2^n k + 1$ be a Carmichael number such that $n \leq X_2$. If $p \mid 2^n k + 1$, then $p = 2^m d + 1$ with $m \leq \log x$, $d \leq y_L$ and $d \mid k$. Taking into account that $d \leq y_L \leq x^{1/2} \leq 2^{\log x} - 1$ for $x > x_0$, it follows that $2^m d + 1 \leq 2^{2 \log x}$, and so

$$2^n \leq 2^n k + 1 \leq \prod_{\substack{m \leq \log x \\ d \leq y_L, d \mid k}} (2^m d + 1) \leq 2^{2(\log x)^2 \tau(k)}.$$

Since $k \notin \mathcal{N}_1(x)$ we have

$$(5) \quad \tau(k) \leq 2^{\Omega(k)} \leq 2^{1.01 \log_2 x} \leq (\log x)^{0.8},$$

and therefore,

$$n \leq 2(\log x)^{2.8} \leq X_3 \quad (x > x_0).$$

Let \mathcal{P}_3 be the set of primes of the form $2^m d + 1$ with $m \geq M$ and $d \leq y_L$, where

$$M := 10 \log_2 x.$$

The estimation in (4) shows that $|\mathcal{P}_3| \leq x^{1/2 - 9\epsilon}$; thus $X_3|\mathcal{P}_3| = o(x)$ as $x \rightarrow \infty$. Also,

$$X_3 \sum_{p \in \mathcal{P}_3} p^{-1} \leq X_3 \left(\sum_{m \geq M} 2^{-m} \right) \left(\sum_{d \leq y_L} d^{-1} \right) \ll (\log x)^{4 - 10 \ln 2} = o(1)$$

as $x \rightarrow \infty$. By Lemma 1 it follows that the set

$$\mathcal{C}_7(x) := \mathcal{S}_6^*(x) \cap \mathcal{F}(\mathcal{P}_3; X_3) = \mathcal{C}_6^*(x) \cap \mathcal{F}(\mathcal{P}_3; X_3)$$

is negligible.

Next, let \mathcal{Q}_1 be the collection of almost primes of the form $q = p_1 p_2$, where $p_1 = 2^{m_1} d + 1$, $p_2 = 2^{m_2} d + 1$, $m_1 < m_2 \leq M$, and $d > z_1$. Here, $M := 10 \log_2 x$ and $z_1 := (\log x)^{10}$ as before. Clearly, the bound

$$|\mathcal{Q}_1| \leq \left| \{ (m_1, m_2, d) : m_1, m_2 \leq M, d \leq y_L \} \right| \leq M^2 y_L \leq x^{1/2 - 9\epsilon}$$

holds if $x > x_0$, and thus $X_3|\mathcal{Q}_1| = o(x)$ as $x \rightarrow \infty$. Also,

$$X_3 \sum_{q \in \mathcal{Q}_1} q^{-1} \leq X_3 \left(\sum_{m \geq 1} 2^{-m} \right)^2 \left(\sum_{d > z_1} d^{-2} \right) \ll \frac{X_3}{z_1} = (\log x)^{-7} = o(1)$$

as $x \rightarrow \infty$. Applying Lemma 1 again, we see that

$$\mathcal{C}_8(x) := \mathcal{S}_7^*(x) \cap \mathcal{F}(\mathcal{Q}_1; X_3) = \mathcal{C}_7^*(x) \cap \mathcal{F}(\mathcal{Q}_1; X_3)$$

is negligible.

Similarly, let \mathcal{Q}_2 be the collection of almost primes of the form $q = p_1 p_2$, where $p_1 = 2^{m_1} d_1 + 1$, $p_2 = 2^{m_2} d_2 + 1$, $m_1 < m_2 \leq M$, $d_1, d_2 \leq y_L$, and $\gcd(d_1, d_2)$ is divisible by some prime $r > z_1$. We have

$$|\mathcal{Q}_2| \leq \left| \{(m_1, m_2, d_1, d_2) : m_1, m_2 \leq M, d_1, d_2 \leq y_L\} \right| \leq M^2 y_L^2 \leq x^{1-19\epsilon}$$

if $x > x_0$, hence $X_3 |\mathcal{Q}_2| = o(x)$ as $x \rightarrow \infty$. Furthermore,

$$\begin{aligned} \sum_{q \in \mathcal{Q}_2} q^{-1} &\leq \left(\sum_{m \geq 1} 2^{-m} \right)^2 \left(\sum_{\substack{d_1 = ru \leq y_L \\ d_2 = rv \leq y_L \\ r > z_1}} (d_1 d_2)^{-1} \right) \\ &\ll \left(\sum_{r > z_1} r^{-2} \right) \left(\sum_{u \leq y_L} u^{-1} \right)^2 \ll (\log x)^{-8}, \end{aligned}$$

and therefore

$$X_3 \sum_{q \in \mathcal{Q}_2} q^{-1} \ll (\log x)^{-5} = o(1) \quad (x \rightarrow \infty).$$

By Lemma 1 the set

$$\mathcal{C}_9(x) := \mathcal{S}_8^*(x) \cap \mathcal{F}(\mathcal{Q}_2; X_3) = \mathcal{C}_8^*(x) \cap \mathcal{F}(\mathcal{Q}_2; X_3)$$

is negligible.

To conclude this subsection, we now show that $\mathcal{S}_9^*(x) = \emptyset$; this implies that $\mathcal{S}(x)$ is contained in $\mathcal{C}_1(x) \cup \dots \cup \mathcal{C}_9(x)$ as claimed.

Suppose on the contrary that $\mathcal{S}_9^*(x) \neq \emptyset$. For each $k \in \mathcal{S}_9^*(x)$ there exists $n \in (X_1, X_3]$ such that $2^n k + 1$ is Carmichael; let

$$(6) \quad 2^n k + 1 = \prod_{j=1}^{\ell} (2^{m_j} d_j + 1)$$

be its factorization into (distinct) primes. Grouping the primes on the right side of (6) according to the size of d_j , we set

$$A := \prod_{\substack{1 \leq j \leq \ell \\ d_j \leq z_1}} (2^{m_j} d_j + 1) \quad \text{and} \quad B := \frac{2^n k + 1}{A}.$$

For every prime $p_j := 2^{m_j} d_j + 1$ dividing A we have $m_j < M$ since $k \notin \mathcal{C}_7(x)$; therefore,

$$p_j \leq 2^{M+1} z_1 = 2^{10 \log_2 x + 1 + (10/\ln 2) \log_2 x} \leq 2^{30 \log_2 x} = 2^{3M}.$$

Taking into account the bound (5), we see that

$$(7) \quad A \leq \prod_{\substack{d|k \\ m < M}} 2^{3M} \leq 2^{3M^2 \tau(k)} \leq 2^{300(\log_2 x)^2 (\log x)^{0.8}} \leq 2^{(\log x)^{0.9}} \quad (x > x_0).$$

On the other hand, every prime $p_j := 2^{m_j} d_j + 1$ dividing B has $d_j > z_1$. Since each $m_j < M$ and $k \notin \mathcal{C}_8(x)$, it follows that the divisors d_j are different for distinct primes p_j dividing B . For any such divisor d_j , factor $d_j = d_j^- d_j^+$, where d_j^- [resp. d_j^+] is the largest divisor of d that is composed solely of primes $\leq z_1$ [resp. $> z_1$]. The numbers $\{d_j^+\}$ are coprime in pairs since $k \notin \mathcal{C}_9(x)$; consequently,

$$\prod_{p_j | B} d_j^+ \leq k$$

as the product on the left side is a divisor of k . As for the numbers $\{d_j^-\}$, we note that

$$d_j^- \leq z_1^{\Omega(z_1; k)} \leq (\log x)^{20 \log_3 x} \leq 2^{(\log_2 x)^2} \quad (x > x_0),$$

where we have used the fact that $k \notin \mathcal{N}_2(x)$ for the second inequality. Putting everything together, we derive the bound

$$(8) \quad B \leq \prod_{p_j | B} 2^{M+1} d_j^- d_j^+ \leq (2^{10 \log_2 x + 1 + (\log_2 x)^2})^{\tau(k)} \prod_{p_j | B} d_j^+ \leq 2^{(\log x)^{0.9}} k$$

for all $x > x_0$. Combining (6), (7) and (8) it follows that

$$2^n k + 1 = AB \leq 2^{2(\log x)^{0.9}} k,$$

and therefore, $n \leq 2(\log x)^{0.9}$. However, since $n > X_1 = (\log x) / \log_2 x$ this is impossible for large x . The contradiction implies that $\mathcal{S}_5^*(x) = \emptyset$ as claimed.

2.4. Large values of $n_0(k)$. Recall that a number k is said to be *powerful* if $p^2 | k$ for every prime p dividing k . We denote

$$\mathcal{C}_{10}(x) := \{k \leq x : k \text{ is powerful}\}.$$

By the well-known bound $|\mathcal{C}_{10}(x)| \ll x^{1/2}$, the set $\mathcal{C}_{10}(x)$ is negligible.

From now on, fix $k \in \mathcal{C}_{10}^*(x)$, and let $n > X_2 := \exp((\log x) / \log_2 x)$ be such that $2^n k + 1$ is a Carmichael number. Also, let $p = 2^m d + 1$ be a fixed prime factor of $2^n k + 1$. For convenience, we denote

$$N_1 := \left\lfloor \sqrt{\frac{n}{\log x}} \right\rfloor \quad \text{and} \quad N_2 := \frac{n}{N_1}.$$

Since numbers of the form $um + vn$ with $(u, v) \in [0, N_1]^2$ all lie in the interval $[0, 2nN_1]$, and there are $(N_1 + 1)^2$ such pairs (u, v) , by the pigeonhole principle there exist $(u_1, v_1) \neq (u_2, v_2)$ such that

$$|(u_1 m + v_1 n) - (u_2 m + v_2 n)| \leq \frac{2N_1 n}{(N_1 + 1)^2 - 1} \leq \frac{2n}{N_1} = 2N_2.$$

Put $u := u_1 - u_2$ and $v := v_1 - v_2$. Then

$$(9) \quad (u, v) \neq (0, 0), \quad \max\{|u|, |v|\} \leq N_1, \quad |um + vn| \leq 2N_2.$$

Replacing u, v with $u/d, v/d$, where d is either $\gcd(u, v)$ or $-\gcd(u, v)$, we can further assume that

$$(10) \quad \gcd(u, v) = 1 \quad \text{and} \quad u \geq 0.$$

From the congruences

$$(11) \quad 2^m d \equiv -1 \pmod{p} \quad \text{and} \quad 2^n k \equiv -1 \pmod{p}$$

we derive that

$$2^{um+vn} d^u k^v \equiv (-1)^{u+v} \pmod{p}.$$

Therefore, p divides the numerator of the rational number

$$G := 2^{um+vn} d^u k^v - (-1)^{u+v}.$$

We claim that $G \neq 0$. Indeed, suppose on the contrary that $G = 0$. Since k and d are both odd, it follows that $um + vn = 0$ and $d^u k^v = 1$. If $u = 0$ or $v = 0$, the first equation implies that $(u, v) = (0, 0)$, which is not allowed; hence $uv \neq 0$, and by (10) we have $u > 0$. Since u and v are coprime, the equality $d^u = k^{-v}$ implies that $k = k_1^u$ for some $k_1 > 1$. As $k \notin \mathcal{C}_{10}(x)$, it follows that $u = 1$. Then, as $d | k$

and $d = k^{-v}$, we also have $v = -1$, $d = k$, and $0 = um + vn = m - n$, so $m = n$. But this shows that $2^n k + 1 = p$, which is not possible since $2^n k + 1$ is a Carmichael number. This contradiction establishes our claim that $G \neq 0$.

Since p divides the numerator of G , using (9) we derive the bound

$$(12) \quad p \leq 2^{|um+vn|} d^{|u|} k^{|v|} + 1 \leq 2^{2N_2+1} x^{2N_1} = 2^{(2+2/\ln 2)N_2+1},$$

which is used below and in §2.5. We also need the following:

Lemma 2. *Let*

$$\Delta_1 := \frac{\sqrt{2}(\log_2 x)^{3/2}}{(\log n)^{1/4}}.$$

For $x > x_0$, the Carmichael number $2^n k + 1$ has no more than $n^{1/3}$ prime divisors $p = 2^m d + 1$ with $m > \Delta_1 N_2$.

Proof. With the minor modifications outlined here, this result is essentially contained in [11, Lemma 7]. The underlying argument is fairly standard (see, for example, [6, 7, 12, 13, 18]), although it relies on a quantitative version of the *Subspace Theorem* due to Evertse [16], a bound of Pontreau [23] on the number of solutions to certain *S-unit equations*, and Baker’s bound on *linear forms in logarithms* (see [21] or [8, Theorem 5]).

Let $p = 2^m d + 1$ be a prime divisor of $2^n k + 1$ with $m > \Delta_1 N_2$. Using the Euclidean algorithm, we write

$$(13) \quad n = mq + r \quad \text{with} \quad 0 \leq r < m \leq 5N_2,$$

where the last inequality is a consequence of (12). Note that

$$(14) \quad q \leq \frac{n}{m} \leq \frac{n}{\Delta_1 N_2} = \Delta_1^{-1} N_1.$$

From (11) we obtain the congruences

$$2^{mq} d^q \equiv (-1)^q \pmod{p} \quad \text{and} \quad 2^{mq+r} k \equiv -1 \pmod{p},$$

hence p divides

$$G := d^q + (-1)^q 2^r k.$$

We claim that $G \neq 0$. Indeed, suppose on the contrary that $G = 0$. Then $r = 0$ (since d is odd), q is odd, and $k = d^q$. As $k \notin \mathcal{C}_{10}(x)$, $q = 1$. But this implies that $d = k$ and $n = mq + r = m$, hence $2^n k + 1 = p$, which is impossible since $2^n k + 1$ is a Carmichael number. This contradiction establishes our claim that $G \neq 0$.

Since p divides G , using (13) and (14) we derive the bound

$$(15) \quad p \leq |G| \leq 2^{r+1} d^q k \leq 2^{r+1} x^{q+1} \leq 2^{(r+1)+(q+1)(\log x)/\ln 2} \\ \leq 2^{(5N_2+1)+(\Delta_1^{-1} N_1+1)(\log x)/\ln 2} \leq 2^{2\Delta_1^{-1} N_2} \quad (x > x_0).$$

We also have the lower bound

$$(16) \quad p - 1 = 2^m d \geq 2^m > 2^{\Delta_1 N_2}.$$

Put

$$U := 2^m d, \quad V_1 := d^q \quad \text{and} \quad V_2 := (-1)^q 2^r k.$$

Then, taking into account the fact that $V_1 + V_2 = G$, the inequalities (15) and (16) together imply that

$$U > |V_1 + V_2|^{\Delta_2} \quad \text{with} \quad \Delta_2 := \frac{1}{2} \Delta_1^2 = \frac{(\log_2 x)^3}{(\log n)^{1/2}}.$$

Taking into account the bound (5) and the combination of [11, Lemmas 2, 3], for $x > x_0$ we see that all but $O(\log_2 x)$ of the triples (U, V_1, V_2) constructed in this manner satisfy the conditions of [11, Lemma 7] if the parameter δ_2 in that lemma is replaced by Δ_2 . Following the proof, we conclude that the bound [11, Equation (47)] on the number $t_1 t_2$ of such triples (U, V_1, V_2) can be replaced by

$$t_1 t_2 \leq 2^{100\mu^2 s} \quad (x > x_0)$$

in our situation, where

$$\mu := 2 \lfloor 3\Delta_2^{-1} \rfloor + 1 \quad \text{and} \quad s := \omega(k) + 2.$$

As $\mu \leq 7\Delta_2^{-1}$ and $s \leq 1.1 \log_2 x$ (since $k \notin \mathcal{N}_1(x)$), we see that

$$100\mu^2 s \leq 5400 \frac{\log n}{(\log_2 x)^5} \leq \frac{\log n}{3 \ln 2} - 1 \quad (x > x_0).$$

Putting everything together, it follows that the Carmichael number $2^n k + 1$ has at most $t_1 t_2 + O(\log_2 x) \leq (\frac{1}{2} + o(1))n^{1/3}$ prime divisors $p = 2^m d + 1$ with $m > \Delta_1 N_2$. The result follows. \square

2.5. The final argument. We continue to use notation introduced earlier.

Put $z_2 := \lfloor \log_4 x \rfloor$, and let $\mathcal{C}_{11}(x)$ be the set of numbers $k \in \mathcal{C}_{10}^*(x)$ such that $q^2 \mid k$ for some $q > z_2$. For any such q the number of $k \leq x$ cannot exceed x/q^2 ; summing over all q we have

$$|\mathcal{C}_{11}(x)| \leq \sum_{q > z_2} \frac{x}{q^2} \ll \frac{x}{z_2} \ll \frac{x}{\log_4 x} = o(x) \quad (x \rightarrow \infty);$$

thus, $\mathcal{C}_{11}(x)$ is a negligible set.

Next, let $\mathcal{C}_{12}(x)$ be the set of $k \in \mathcal{C}_{11}^*(x)$ with the property that there is a prime q such that $q^{z_2} \mid k$. For any such q the number of $k \leq x$ does not exceed x/q^{z_2} . Also, since $z_2 > 2$ for $x > x_0$ and $k \notin \mathcal{C}_{11}(x)$, it follows that $q \leq z_2$. Consequently,

$$|\mathcal{C}_{12}(x)| \leq \sum_{q \leq z_2} \frac{x}{q^{z_2}} \leq \frac{x \cdot \pi(z_2)}{2^{z_2}} \leq \frac{2x \log_4 x}{(\log_3 x)^{\ln 2}} = o(x) \quad (x \rightarrow \infty),$$

hence, $\mathcal{C}_{12}(x)$ is negligible.

Finally, we put $\mathcal{C}_{13}(x) := \mathcal{C}_{12}^*(x)$. To complete the proof of Theorem 1 it is enough to show that $\mathcal{C}_{13}(x)$ is negligible. We begin by noting that for every $k \notin \mathcal{N}_1(x)$ the bound

$$n \leq K_1 := \exp((\log x)^4)$$

holds whenever $2^n k + 1$ is Carmichael; in fact, it is an easy consequence of (2) since $\tau(k) \leq (\log x)^{0.8}$ (by (5)) and $\omega(k) \leq \Omega(k) \leq 1.01 \log_2 x$.

In particular, for every $k \in \mathcal{C}_{13}(x)$ there exists $n \in [X_2, K_1]$ such that $2^n k + 1$ is a Carmichael number. The interval $[X_2, K_1]$ can be covered with at most $O(\log K_1) = O((\log x)^4)$ intervals of the form $[a, 2a)$. Thus, if we denote by $\mathcal{C}_{13}(a; x)$ the set of $k \in \mathcal{C}_{13}(x)$ such that $2^n k + 1$ is a Carmichael number for some $n \in [a, 2a)$, we have

$$|\mathcal{C}_{13}(x)| \ll (\log x)^4 \max_{X_2 \leq a \leq K_1} |\mathcal{C}_{13}(a; x)|,$$

hence it suffices to show that

$$(17) \quad \max_{X_2 \leq a \leq K_1} |\mathcal{C}_{13}(a; x)| \ll \frac{x}{(\log x)^5}.$$

From now on, we work to prove (17).

Now, fix $a \in [X_2, K_1]$ and $k \in \mathcal{C}_{13}(a; x)$, and let $n \in [a, 2a]$ be such that $N := 2^n k + 1$ is Carmichael. Let \mathcal{P} denote the set of prime divisors $p = 2^m d + 1$ of N with $m > \Delta_1 N_2$. Put

$$A := \prod_{\substack{p \mid 2^n k + 1 \\ p \in \mathcal{P}}} p \quad \text{and} \quad B := \frac{2^n k + 1}{A}.$$

Since every prime $p \mid N$ satisfies (12), and $|\mathcal{P}| \leq n^{1/3}$ by Lemma 2, we have

$$(18) \quad A \leq (2^{5N_2})^{n^{1/3}} = 2^{5n^{5/6}(\log x)^{1/2}} \leq 2^{10a^{5/6}(\log x)^{1/2}} \quad (x > x_0).$$

Put $s := \lfloor \log_2 x \rfloor$ and $z_3 := (\log x)^{0.9}$. We split the prime factors of B into three sets according to the following types:

- (i) Primes $p = 2^m d + 1$ of *type I* are those for which either $m \leq a^{1/3}$, or p divides $2^{n_j} k_j + 1$ for $j = 1, \dots, s$, where k_1, \dots, k_s are distinct numbers in $\mathcal{C}_{13}(a; x)$ and $n_1, \dots, n_s \in [a, 2a]$.
- (ii) Primes $p = 2^m d + 1$ of *type II* have the property that $2^t d + 1$ is a prime factor of B for at most 100 values of t in the interval $[m, m + z_3]$.
- (iii) Primes p of *type III* are prime factors of B that are neither of type *I* nor of type *II*.

Factor $B = B_I B_{II} B_{III}$, where

$$B_I := \prod_{\substack{p \mid B \\ p \text{ of type I}}} p, \quad B_{II} := \prod_{\substack{p \mid B \\ p \text{ of type II}}} p \quad \text{and} \quad B_{III} := \prod_{\substack{p \mid B \\ p \text{ of type III}}} p.$$

Our approach is to show that primes of type *I* are small, whereas primes of type *II* are few in number. As for primes of type *III*, there may be many for a given k ; however, we show that there are only a few such primes on average, and this is sufficient to finish the proof.

Case 1. Primes of type *I*.

Let $p := 2^m d + 1$ be a prime of type *I*. Since $d \leq x$ for all $p \mid B$, in the case that $m \leq a^{1/3}$ it is easy to see that

$$(19) \quad m \leq M_3 := 10a^{1/3} \log x \quad \text{and} \quad p \leq 2^{M_3} \quad (x > x_0).$$

Our goal is to show that (19) holds for every type *I* prime. Assuming this result for the moment and using (5), we derive the bound

$$(20) \quad B_I \leq \prod_{\substack{m \leq M_3 \\ d \mid k}} 2^{M_3} \leq 2^{M_3^2 \tau(k)} \leq 2^{a^{2/3} (\log x)^3} \quad (x > x_0).$$

Now suppose that $p := 2^m d + 1$ is of type *I* with $m > a^{1/3}$, and let k_1, \dots, k_s and n_1, \dots, n_s have the properties described in (i). We claim that there are two numbers k_j , say k_1 and k_2 , for which there exists a prime q dividing k_2 but not k_1 ; in particular, since d divides each k_j , q does not divide d . Indeed, suppose on the contrary that every k_j is divisible by the primes q_1, \dots, q_t , which we order by

$$q_1 < \dots < q_r \leq z_2 < q_{r+1} < \dots < q_t$$

with $0 \leq r \leq t$. Since $k_j \notin \mathcal{C}_{11}(x) \cup \mathcal{C}_{12}(x)$ for each j , it follows that

$$k_j = q_{r+1} \cdots q_t \prod_{i=1}^r q_i^{\alpha_{i,j}} \quad \text{with} \quad 1 \leq \alpha_{i,j} \leq z_2 \quad (1 \leq i \leq r, 1 \leq j \leq s).$$

As s cannot exceed the number of all such factorizations, we have (using the bound $\pi(u) \leq 2u/\log u$ for all large u)

$$|\log_2 x| = s \leq z_2^r \leq z_2^{\pi(z_2)} \leq \exp(2z_2) \leq (\log_3 x)^2,$$

which is impossible for $x > x_0$. This contradiction proves the claim.

Next, we apply a three-dimensional analogue of the argument used in §2.4 to derive inequality (12).

Put $N_3 := \lceil (2a)^{1/3} \rceil$. Since $\max\{m, n_1, n_2\} \leq 2a = N_3^3$, all numbers of the form $um + vn_1 + wn_2$ with $(u, v, w) \in [0, N_3]^3$ lie in the interval $[0, 3N_3^4]$; as there are $(N_3 + 1)^3$ such triplets (u, v, w) , it follows that there exist $(u_1, v_1, w_1) \neq (u_2, v_2, w_2)$ for which

$$|(u_1m + v_1n_1 + w_1n_2) - (u_2m + v_2n_1 + w_2n_2)| \leq \frac{3N_3^4}{(N_3 + 1)^3 - 1} \leq 3N_3.$$

Put $(u, v, w) := (u_1 - u_2, v_1 - v_2, w_1 - w_2) \neq (0, 0, 0)$, and note that

$$(21) \quad \max\{|u|, |v|, |w|\} \leq N_3, \quad |um + vn_1 + wn_2| \leq 3N_3.$$

In view of the congruences

$$2^m d \equiv -1 \pmod{p} \quad \text{and} \quad 2^{n_j} k_j \equiv -1 \pmod{p} \quad (j = 1, 2),$$

we have

$$2^{um+vn_1+wn_2} d^u k_1^v k_2^w \equiv (-1)^{u+v+w} \pmod{p}.$$

Therefore, p divides the numerator of the rational number

$$G := 2^{um+vn_1+wn_2} d^u k_1^v k_2^w - (-1)^{u+v+w}.$$

We claim that $G \neq 0$. Indeed, suppose on the contrary that $G = 0$. Since dk_1k_2 is odd, it follows that $um + vn_1 + wn_2 = 0$, $u + v + w$ is even, and $d^u k_1^v k_2^w = 1$. Since there is a prime q that divides k_2 but neither k_1 nor d , it follows that $w = 0$, and therefore

$$2^{um+vn_1} d^u k_1^v = (-1)^{u+v}.$$

However, by the arguments of §2.4 we see this relation is not possible unless $(u, v) = (0, 0)$; but this leads to $(u, v, w) = (0, 0, 0)$, which is not allowed. We conclude that $G \neq 0$.

Since p divides the numerator of G , using (21) we derive the bound

$$p \leq 2^{|um+vn_1+wn_2|} d^{|u|} k_1^{|v|} k_2^{|w|} + 1 \leq 2^{3N_3+1} x^{3N_3} \leq 2^{M_3} \quad (x > x_0).$$

Since $p > 2^m$, this establishes the promised result that (19) holds for every type I prime.

Case 2. Primes of type II.

We first observe that every prime factor $p = 2^m d + 1$ of B satisfies

$$(22) \quad m \leq \Delta_1 N_2 \leq \frac{2a^{1/2}(\log x)^{1/2}(\log_2 x)^{3/2}}{(\log n)^{1/2}} \leq M_4 := 2a^{1/2}(\log_2 x)^2,$$

where we have used the fact that

$$\log n > \log X_2 = \frac{\log x}{\log_2 x}.$$

Let d be fixed and split the interval $[0, M_4]$ into subintervals \mathcal{I}_j of length z_3 , where $\mathcal{I}_j := [jz_3, (j + 1)z_3)$ for $j = 0, \dots, \lfloor M_4/z_3 \rfloor$. Every such \mathcal{I}_j contains at most 100

indices m for which $p = 2^m d + 1$ is a type II prime factor of $2^n k + 1$; these primes clearly satisfy

$$p = 2^m d + 1 \leq 2^{2M_4} \quad (x > x_0).$$

Thus, for fixed d we have

$$\prod_{\substack{p|B_{II} \\ p=2^m d+1}} p \leq (2^{2M_4})^{100(M_4/z_3+1)} \leq 2^{300M_4^2/z_3} \quad (x > x_0).$$

Then, taking the product over all divisors d of k , we derive that

$$B_{II} \leq 2^{300M_4^2\tau(k)/z_3} \quad (x > x_0).$$

Finally, using (5) and the definitions of M_4 and z_3 , for all $x > x_0$ we have

$$\frac{300M_4^2\tau(k)}{z_3} \leq \frac{1200a(\log_2 x)^4(\log x)^{0.8}}{(\log x)^{0.9}} \leq \frac{a}{(\log x)^{0.09}} \quad (x > x_0)$$

hence we obtain the bound

$$(23) \quad B_{II} \leq 2^{a/(\log x)^{0.09}} \quad (x > x_0).$$

Case 3. Primes of type III.

Combining the bounds (18), (20) and (23), we have

$$AB_I B_{II} \leq 2^{10a^{5/6}(\log x)^{1/2} + a^{2/3}(\log x)^3 + a/(\log x)^{0.09}} \leq 2^{a/2} \quad (x > x_0);$$

therefore, since

$$2^a \leq 2^n k + 1 = AB = AB_I B_{II} B_{III},$$

it follows that

$$(24) \quad B_{III} \geq 2^{a/2} \quad (x > x_0).$$

We now adopt the convention that for every $k \in \mathcal{C}_{13}(a; x)$, the number n is chosen to be the least integer in $[a, 2a)$ such that $2^n k + 1$ is a Carmichael number. With this convention in mind, we use the notation $B_{III}(k)$ instead of B_{III} to emphasize that this number depends only on k .

Multiplying the bounds (24) over all $k \in \mathcal{C}_{13}(a; x)$, we get

$$(25) \quad 2^{(a/2)|\mathcal{C}_{13}(a;x)|} \leq \prod_{k \in \mathcal{C}_{13}(a;x)} B_{III}(k) \leq \left(\prod_{p \in \mathcal{B}_a} p \right)^s,$$

where we have used \mathcal{B}_a to denote the collection of type III primes that divide some $B_{III}(k)$ with $k \in \mathcal{C}_{13}(a; x)$. Note that every prime in \mathcal{B}_a is repeated no more than s times since p is not of type I .

Let $p = 2^m d + 1 \in \mathcal{B}_a$. Since $d \leq x$ and $m \geq a^{1/3} \geq X_2^{1/3} \geq 2 \log x$ for all $x > x_0$, it follows that $p \leq 2^{2m}$. Thus, fixing m and denoting by $\mathcal{D}_{a,m}$ the set of numbers d for which $2^m d + 1 \in \mathcal{B}_a$, it follows that

$$\prod_{d \in \mathcal{D}_{a,m}} (2^m d + 1) \leq 2^{2m|\mathcal{D}_{a,m}|} \leq 2^{2M_4|\mathcal{D}_{a,m}|},$$

where we used (22) for the second inequality. Taking the product over all values of $m \leq M_4$, we have for $x > x_0$:

$$(26) \quad \prod_{p \in \mathcal{B}_a} p \leq 2^{2M_4^2 D_a} \quad \text{with} \quad D_a := \max_{m \leq M_4} |\mathcal{D}_{a,m}|.$$

Hence, to get an upper bound for the product in (26), it suffices to find a uniform upper bound for D_a .

Observe that, as the primes in \mathcal{B}_a are not of type II , every $d \in \mathcal{D}_{a,m}$ has the property that $2^t d + 1$ is prime for at least 100 values of t in the interval $[m, m + z_3]$. Let m be fixed, and let $\lambda_1 < \dots < \lambda_{100}$ be fixed integers in the interval $[0, z_3]$. We begin by counting the number of $d \leq x$ for which the 100 numbers $\{2^{m+\lambda_j} d + 1 : 1 \leq j \leq 100\}$ are simultaneously prime. By the Brun sieve, the number of such $d \leq x$ is

$$O\left(\frac{x}{(\log x)^{100}} \left(\frac{E}{\varphi(E)}\right)^{100}\right), \quad \text{where } E := \prod_{i < j} (2^{\lambda_j - \lambda_i} - 1).$$

Since

$$E \leq 2^{100^2 z_3} \leq 2^{10^4 \log x} = x^{10^4 \ln 2},$$

using the well-known bound $u/\varphi(u) \ll \log_2 u$ we have

$$\frac{E}{\varphi(E)} \ll \log_2 E \ll \log_2 x.$$

Hence, for fixed $\lambda_1 < \dots < \lambda_{100}$ the number of possibilities for d is

$$O\left(\frac{x(\log_2 x)^{100}}{(\log x)^{100}}\right).$$

As the number of choices for $\lambda_1, \dots, \lambda_{100}$ in $[0, z_3]$ is $\leq (z_3 + 1)^{100} \ll (\log x)^{90}$, it follows that

$$|\mathcal{D}_{a,m}| \ll \frac{x(\log_2 x)^{100}}{(\log x)^{10}}.$$

Consequently,

$$D_a := \max_{m \leq M_4} |\mathcal{D}_{a,m}| \leq \frac{x}{(\log x)^9} \quad (x > x_0),$$

and we have

$$(27) \quad 2M_4^2 D_a \leq \frac{8ax(\log_2 x)^4}{(\log x)^9} \leq \frac{ax}{(\log x)^8} \quad (x > x_0).$$

Inserting estimate (27) into (26), and combining this with (25), we see that

$$2^{(a/2)|\mathcal{C}_{13}(a;x)|} \leq 2^{axs/(\log x)^8},$$

and therefore

$$|\mathcal{C}_{13}(a;x)| \leq \frac{2xs}{(\log x)^8} \leq \frac{2x \log_2 x}{(\log x)^8} \quad (x > x_0).$$

Since this bound clearly implies (17), our proof of Theorem 1 is complete.

3. PROOF OF THEOREM 2

The following statement provides the key to the proof of Theorem 2.

Theorem 4 (Matomäki). *If $\gcd(b, m) = 1$ and b is a quadratic residue mod m , then for all large x there are $\gg_m x^{1/5}$ Carmichael numbers up to x in the arithmetic progression $b \pmod m$.*

In the recent preprint [29], Wright extends the previous theorem to remove the condition on b being a quadratic residue modulo m . Precisely, he showed (under $\gcd(b, m) = 1$) that the number of Carmichael numbers up to x that are congruent to $b \pmod m$ is $\gg x^{\frac{K}{(\log_3 x)^2}}$, for some constant $K > 0$. Using this result would allow a somewhat easier approach to the problem, but we prefer to use Matomäki’s Theorem 4, since it gives a better lower bound for the count.

The next proposition illustrates our approach to the proof of Theorem 2.

Proposition 1. *For all large x , there are $\gg x^{1/5}$ natural numbers up to x that are both Sierpiński and Carmichael.*

Proof. In view of Theorem 4, to prove this result it suffices to find coprime b, m such that b is a quadratic residue mod m , and every sufficiently large number in the arithmetic progression $b \pmod m$ is a Sierpiński number.

Suppose that we can find a finite collection $\mathcal{C} := \{(a_j, n_j; b_j, p_j)\}_{j=1}^N$ of ordered quadruples of integers with the following properties:

- (i) n_1, \dots, n_N are natural numbers, and p_1, \dots, p_N are distinct primes;
- (ii) every integer lies in at least one of the arithmetic progressions $a_j \pmod{n_j}$;
- (iii) $p_j \mid 2^{n_j} - 1$ for each j ;
- (iv) $p_j \mid 2^{a_j} b_j + 1$ for each j ;
- (v) b_j is a quadratic residue mod p_j for each j .

Put $m := p_1 \cdots p_N$, and let $b \in \mathbb{Z}$ be such that $b \equiv b_j \pmod{p_j}$ for each j . Since p_1, \dots, p_N are distinct primes, it is clear from (v) that b is a quadratic residue mod m . Let k be an arbitrary element of the arithmetic progression $b \pmod m$ that exceeds $\max\{p_1, \dots, p_N\}$. For every $n \in \mathbb{Z}$ there exists j such that $n \equiv a_j \pmod{n_j}$. For such j , using (iii) and (iv) one sees that $p_j \mid 2^n k + 1$, hence $2^n k + 1$ is composite since $k > p_j$. As this is so for every $n \in \mathbb{Z}$, it follows that k is Sierpiński.

To complete the proof of the theorem it suffices to observe that

$$(28) \quad \mathcal{C} := \{(1, 2; 1, 3), (2, 4; 1, 5), (4, 8; 1, 17), (8, 16; 1, 257), \\ (16, 32; 1, 65537), (32, 64; 1, 641), (0, 64; -1, 6700417)\}$$

is a collection with the properties (i) – (v). □

Proof of Theorem 2. In view of Theorem 4, it suffices to find coprime b, m such that b is a quadratic residue mod m , and every sufficiently large number in the arithmetic progression $b \pmod m$ is both Sierpiński and Riesel.

Suppose that we can find two finite collections $\mathcal{C} := \{(a_j, n_j; b_j, p_j)\}_{j=1}^N$ and $\mathcal{C}' := \{(c_j, m_j; d_j, q_j)\}_{j=1}^M$ such that \mathcal{C} has the properties (i)–(v) listed in Proposition 1, and \mathcal{C}' has the properties:

- (vi) m_1, \dots, m_N are natural numbers, and q_1, \dots, q_N are distinct primes;
- (vii) the union of the arithmetic progressions $c_j \pmod{m_j}$ is \mathbb{Z} ;
- (viii) $q_j \mid 2^{m_j} - 1$ for each j ;
- (ix) $q_j \mid 2^{c_j} d_j - 1$ for each j ;
- (x) d_j is a quadratic residue mod q_j for each j .

Furthermore, assume that

$$(xi) \quad \gcd(p_1 \cdots p_N, q_1 \cdots q_M) = 1.$$

Put $m := p_1 \cdots p_N q_1 \cdots q_M$, and let $b \in \mathbb{Z}$ be such that $b \equiv b_i \pmod{p_i}$ for $i = 1, \dots, N$ and $b \equiv d_j \pmod{q_j}$ for $j = 1, \dots, M$. Since all the primes p_i and q_j are distinct, it is clear from (v) that b is a quadratic residue mod m . Arguing as in the

proof of Proposition 1 we see that every sufficiently large number in the arithmetic progression $b \pmod m$ is both Sierpiński (using (iii) and (iv)) and Riesel (using (viii) and (ix)).

Hence, to prove the theorem it suffices to exhibit collections \mathcal{C} and \mathcal{C}' with the stated properties. For this, we take \mathcal{C} to be the collection listed in (28), whereas for \mathcal{C}' we use the collection disclosed in the Appendix. \square

4. PROOF OF THEOREM 3

Let us now suppose that $N := 2^n k + 1$ is Lehmer. We can clearly assume that $n \geq 150 \log k$, and by Wright [28] we must have $k \geq 3$; therefore,

$$(29) \quad 1 \leq \omega(k) \leq \frac{\log k}{\log 3} < \frac{n}{150}.$$

Since every Lehmer number is Carmichael, we can apply the following lemma, which is a combination of [11, Lemmas 2, 3, 4].

Lemma 3. *Suppose that $p = 2^m d + 1$ is a prime divisor of the Carmichael number $N = 2^n k + 1$, where $d \mid k$ and $n > 3 \log k$.*

- (i) *If $d = 1$, then $m = 2^\alpha$ for some integer $\alpha \geq 0$, and $p < k^2$.*
- (ii) *If $d > 1$ and the numbers $2^m d$ and $2^n k$ are multiplicatively dependent, then $p < 2^{n/3} k^{1/3} + 1$.*
- (iii) *If $d > 1$ and the numbers $2^m d$ and $2^n k$ are multiplicatively independent, then $m < 7\sqrt{n \log k}$.*

Moreover, N has at most one prime divisor for which (ii) holds.

Let A_1, A_2, A_3 respectively denote the product of the primes $p \mid N$ for each possibility (i), (ii), (iii) in Lemma 3. If $A_1 > 1$ and $p = 2^{2^\alpha} + 1$ is the largest prime dividing A_1 , then we have

$$(30) \quad A_1 \leq \prod_{j=0}^{\alpha} (2^{2^j} + 1) = 2^{2^{\alpha+1}} - 1 = (p - 1)^2 - 1 \leq p^2 \leq k^4,$$

and clearly Lemma 3 implies that

$$(31) \quad A_2 \leq 2^{n/3} k^{1/3} + 1 \leq 2^{n/3+1} k^{1/3}.$$

Furthermore, if the prime divisors of A_3 are $p_j := 2^{m_j} d_j + 1$, $j = 1, \dots, r$, then

$$d_1 \cdots d_r \mid \varphi(A_3) \mid \varphi(N) \mid N - 1 = 2^n k,$$

so we see that $d_1 \cdots d_r \mid k$ and $r \leq \omega(k)$. Consequently,

$$(32) \quad A_3 = \prod_{j=1}^r (2^{m_j} d_j + 1) \leq \prod_{j=1}^r 2^{m_j+1} d_j \leq 2^{(7\sqrt{n \log k} + 1)\omega(k)} k.$$

Combining (30), (31) and (32), it follows that

$$2^n k \leq N = A_1 A_2 A_3 \leq 2^{n/3+1+(7\sqrt{n \log k} + 1)\omega(k)} k^{16/3}.$$

Taking the logarithm and using the inequalities of (29) we derive that

$$\begin{aligned} n &\leq \frac{n}{3} + 1 + (7\sqrt{n \log k} + 1)\omega(k) + \frac{13 \log k}{3 \ln 2} \\ &\leq \frac{n}{3} + (7\sqrt{n \log k})\omega(k) + \frac{19n}{450 \ln 2}, \end{aligned}$$

and it follows that

$$n \leq 49 \left(\frac{2}{3} - \frac{19}{450 \ln 2} \right)^{-2} \omega(k)^2 \log k \leq 150 \omega(k)^2 \log k$$

as stated.

5. APPENDIX A

The collection \mathcal{C}' that is needed for our proof of Theorem 2 (see §3) consists of the quadruples $(c_j, m_j; d_j, q_j)$ disclosed in the following tables.

c_j	m_j	d_j	q_j
0	2	1	3

6. APPENDIX B

We conclude with examples of Sierpiński-Carmichael, Riesel-Carmichael, and Sierpiński-Riesel-Carmichael numbers. The idea behind the construction is the same for each of the three examples. We construct a Carmichael number of the form $N = f(t) = (2t + 1)(4t + 1)(6t + 1)$, where each of the factors $2t + 1$, $4t + 1$ and $6t + 1$ is prime. We can then check that N is Carmichael since $2t$, $4t$ and $6t$ are easily seen to be factors of $N - 1$. What remains is to construct the coverings necessary to produce Sierpiński or Riesel numbers (or both): we have called the elements in these coverings $(c_j, m_j; d_j, q_j)$ throughout this article. The final step is to solve the congruence $f(t_j) \equiv d_j \pmod{q_j}$. Thus, we have an additional column for t_j in the tables presented below.

Sierpiński-Carmichael number. Let $f(t) = (6t + 1)(12t + 1)(18t + 1)$.

c_j	m_j	d_j	q_j	t_j
1	2	1	3	0
2	4	1	5	0
4	8	1	17	0
8	16	1	257	0
16	32	1	65537	0
0	48	96	97	76
16	24	226	241	42
32	96	655316	2225377	9066929

Now observe that (c_j, m_j) forms a covering, $t = 1034170868575402949878725$ satisfies all the congruences $t_j \pmod{q_j}$, and that $f(t) \equiv d_j \pmod{q_j}$ for each j . Thus, for this value of t , $f(t)$ is Sierpiński. To see that $f(t) = 1433447863276475102293771681784302201846076475365432242305613689102632631601$ is also Carmichael, notice that $6t + 1 = 6205025211452417699272351$, $12t + 1 = 12410050422904835398544701$, and $18t + 1 = 18615075634357253097817051$ are all prime, and $f(t) - 1$ is divisible by $6t$, $12t$, and $18t$.

Riesel-Carmichael number. Let $f(t) = (2t + 1)(4t + 1)(6t + 1)$.

c_j	m_j	d_j	q_j	t_j
0	2	1	3	0
0	3	1	7	0
4	9	32	73	1
5	12	11	13	5
7	8	2	17	11
11	18	14	19	11
25	36	13	37	22
11	48	53	97	44
1	36	55	109	28
19	24	32	241	73
3	16	225	257	196
37	48	29	673	210

Again, the congruences $c_j \pmod{m_j}$ form a covering. Moreover, observe that $t = 383045479078858981706118$ satisfies all the congruences $t_j \pmod{q_j}$, and that $f(t) \equiv d_j \pmod{q_j}$ for each j . Thus, for this value of t , $f(t)$ is Riesel. To see that $f(t) = 2697691354484186943747008650234933049993410660498697822360729113096591609$ is also Carmichael, notice that $2t + 1 = 766090958157717963412237$, $4t + 1 = 1532181916315435926824473$, and $6t + 1 = 2298272874473153890236709$ are all prime, and $f(t) - 1$ is divisible by $2t$, $4t$, and $6t$.

Sierpiński-Riesel-Carmichael number. Let $f(t) = (2t + 1)(4t + 1)(6t + 1)$.

c_j	m_j	d_j	q_j	t_j
1	2	1	3	0
0	4	4	5	3
6	12	1	13	0
4	9	41	73	8
10	18	10	19	1
2	24	60	241	91
14	36	16	37	14
34	36	105	109	1
38	72	325	433	91
62	72	37713	38737	1256
0	2	1	3	0
0	3	1	7	0
0	5	1	31	0
5	8	8	17	10
1	10	6	11	1
2	15	38	151	32
11	16	32	257	141
3	20	36	41	26
7	30	75	331	196
3	32	57345	65537	51629
9	40	59633	61681	59393
7	48	72	97	54
19	48	641	673	224
59	60	2	61	26
13	60	1028	1321	129
79	80	2	4278255361	1351662299
113	120	128	4562284561	3018421270

In the table above, the congruence $c_j \pmod{m_j}$ in the top part of the table form a covering, and the congruences in the bottom part of the table form a separate covering. The integer

$t = 1338979105545414811992186692235778298273840303222085925082378476296462844923$ satisfies all of the congruences $t_j \pmod{q_j}$ in the entire table. Thus, $f(t) \equiv d_j \pmod{q_j}$ for both the top and bottom parts of the table. This implies that $f(t)$ is both Sierpiński (from the top part) and Riesel (from the bottom part). Finally,

$$f(t) = 115229224052855887100756588659264307276443422419402462627311319917631839876768 - 543292399537807831615677851203822707234896300064793740772960178584232868017442980971 - 810181759397938835296681335113793727167516391877007957575147486369$$

is Carmichael, since the factors

$$2t + 1 = 2677958211090829623984373384471556596547680606444171850164756952592925689847,$$

$$4t + 1 = 5355916422181659247968746768943113193095361212888343700329513905185851379693, \text{ and}$$

$$6t + 1 = 803387463327248887195312015341466978964304181933251555049427085777877069539$$

are all prime, and $f(t) - 1$ is divisible by $2t$, $4t$, and $6t$.

ACKNOWLEDGMENTS

The authors thank the referee for a careful reading of the manuscript and for useful suggestions, and Jan-Hendrik Evertse for helpful advice and for providing some references. They also thank Pedro Berrizbeitia for an enlightening conversation. The third-named author was supported in part by Project PAPIIT 104512 and

a Marcos Moshinsky fellowship. The fourth-named author would like to acknowledge support from NSF grant DMS-1001180. The fifth-named author acknowledges sabbatical support from the Naval Postgraduate School.
