UNIQUENESS OF THE FIXED POINT OF NONEXPANSIVE SEMIDIFFERENTIABLE MAPS

MARIANNE AKIAN, STÉPHANE GAUBERT, AND ROGER NUSSBAUM

Abstract. We consider semidifferentiable (possibly nonsmooth) maps, acting on a subset of a Banach space, that are nonexpansive either in the norm of the space or in Hilbert’s or Thompson’s metric inherited from a convex cone. We show that the global uniqueness of the fixed point of the map, as well as the geometric convergence of every orbit to this fixed point, can be inferred from the semidifferential of the map at this point. In particular, we show that the geometric convergence rate of the orbits to the fixed point can be bounded in terms of Bonsall’s nonlinear spectral radius of the semidifferential. We derive similar results concerning the uniqueness of the eigenline and the geometric convergence of the orbits to it, in the case of positively homogeneous maps acting on the interior of a cone, or of additively homogeneous maps acting on an AM-space with unit. This is motivated in particular by the analysis of dynamic programming operators (Shapley operators) of zero-sum stochastic games.

1. Introduction

Nonlinear maps acting on a subset of a Banach space, that are nonexpansive either in the norm of the space or in metrics inherited from a convex cone, like Hilbert’s or Thompson’s metric, arise in a number of fields, including population dynamics [Per07], entropy maximization and scaling problems [MS69][BLN94], renormalization operators and fractal diffusions [Sab97][Met05], mathematical economy [Mor64], mathematical biology [AS08], optimal filtering [Bou95], optimal control [CT80][AG03] and zero-sum games [Kol92][PV97][RS01][Ney03][AGG12]. In particular, the dynamic programming operators, known as Bellman operators in control theory, or as Shapley operators in game theory, turn out to be, under standard assumptions, sup-norm nonexpansive maps defined on a space of continuous functions.

Such nonexpansive maps include as a special case the nonnegative matrices and positive linear operators arising in Perron-Frobenius theory. A number of works, including [KR48][Bir57][Bir62][Hop63][Kra64][BK66][Pot77][Bus86][Nus88][Nus89][Kra01][NVL99][GG04][AGLN06][HJ10a][HJ10b][GV12][LN12], have dealt with the extension of Perron-Frobenius theory to the nonlinear case.
In particular, a central problem is to give conditions which allow one to check whether a given fixed point is globally unique, and whether all the orbits of the maps converge to it.

This problem was considered by Nussbaum in [Nus88], who gave general conditions in the case of differentiable maps. Several results in [Nus88] show, in various settings, that a given fixed point of the map is globally unique as soon as the differential of the map at this fixed point does not have any nontrivial fixed point, provided some mild compactness condition is satisfied. Similarly, the global geometric convergence of all the orbits of the map to this fixed point is guaranteed if the spectral radius of the same differential is strictly less than one. Analogous results are derived in [Nus88] for nonlinear eigenvectors.

In a number of applications, including the ones arising from control and games, differentiability assumptions turn out to be too restrictive, since Bellman or Shapley operators are typically nonsmooth (smoothness being related to the uniqueness of the optimal action). However, such operators often satisfy a weaker condition, semidifferentiability, which was first introduced by Penot [Pen82], and which has become a basic notion in variational analysis; see in particular the book by Rockafellar and Wets [RW98].

The case of nondifferentiable convex Shapley operators (corresponding to one-player stochastic games) was studied by Akian and Gaubert in [AG03]. It was shown there that the dimension of the fixed point set can be bounded by considering the subdifferential of the operator at any fixed point (in particular, the uniqueness of this fixed point, perhaps up to an additive constant, can be guaranteed by considering this subdifferential), and that the asymptotic behavior of the orbits could also be inferred from this subdifferential.

In this paper, we show that the general principle, developed in [Nus88] in the differentiable case and in [AG03] in the convex nondifferentiable case, carries over to the nonconvex semidifferentiable case: the global uniqueness of the fixed point of a nonexpansive map, and the geometric convergence of the orbits to it, can be guaranteed by considering only the infinitesimal behavior of the map at the fixed point.

Our main results are Theorem 6.1 dealing with the uniqueness of the fixed point, and Theorem 6.8 dealing with the geometric convergence of the orbits. We also derive in §7 similar results for the uniqueness of the normalized eigenvector, and for the convergence of the orbits, in the case of homogeneous maps acting on the interior of a normal cone and nonexpansive in Hilbert’s or Thompson’s metric. Note that the spectral radius arising in the differentiable case is replaced by Bonsall’s cone spectral radius in the semidifferentiable case. Moreover, to state the uniqueness result, a nonlinear Fredholm-type compactness is required. In this way, we generalize to the case of semidifferentiable maps (Theorem 7.3 and Corollaries 7.7 and 10.5) some of the main results of [Nus88], including Theorem 2.5 there. Note that the present results are already new in the finite dimensional case. Then, the technical compactness conditions are trivially satisfied.

We remark in passing that there are interesting classes of cone maps $f : C \to C$ which are differentiable on the interior of the cone $C$ but only semidifferentiable on the boundary of $C$. See, for example, the class $\mathcal{M}_-$ treated in [Nus89]. Properties equivalent to semidifferentiability (see e.g. Theorem 3.1 there) have been used there.
to prove the existence of eigenvectors in the interior of $C$ for some such maps $f$. However, we shall not pursue this line of application here.

As an illustration of our results, we analyze a simple zero-sum stochastic repeated game (§11). (The application to zero-sum games will be discussed in more detail in a further work.) We note in this respect that the spectral radius of the semidifferential of a Shapley operator can be computed using the results of the companion work [AGN11], which yields explicit formulae for the geometric contraction rate.

The paper is organized as follows. Some basic definitions and results concerning convex cones, Hilbert’s and Thompson’s metrics, are recalled in §2. Preliminary results concerning semidifferentiable maps are established in §3. Then, in §4 we examine the semidifferentials of order preserving or nonexpansive maps. The needed results concerning the different notions of nonlinear spectral radius, and in particular Bonsall’s cone spectral radius, are recalled in §5 (these results are essentially taken from [MPN02] and [AGN11]). Then, the main results of the paper, concerning the uniqueness of the fixed point and the geometric convergence of the orbits, are established in §6. The corollaries of these results concerning nonlinear eigenvectors of homogeneous maps leaving invariant the interior of a cone are derived in §7. Note that the proofs in §§6 and 7 are based on the metric fixed point technique (approximation of the map by a strictly contracting map). In particular, in the case of Hilbert’s or Thompson’s metric, the need to work with a complete metric space limits the scope of these results to normal cones. Hence, alternative uniqueness results, using degree theory arguments, which are valid more generally in proper (closed, convex, and pointed) cones, are presented in §8. Then, in §9 the results are specialized to differentiable maps and are compared with the ones of [Nus88]. Finally, in §10 the present results are adapted to the additive setting (order preserving and additively homogeneous maps acting on an AM-space with unit, or equivalently, on a space of continuous functions $C(K)$ for some compact set $K$). They are illustrated in §11 by the analysis of an example of a zero-sum stochastic game (a variant of the Richman [LLP+99] or stochastic tug-of-war games [PSSW09]).

2. Preliminary results about Hilbert’s and Thompson’s metrics

In this section, we recall classical notions about cones, and recall or establish results which will be used in the following sections. See [Nus88, Chapter 1] and [Nus94, Section 1] for more background.

2.1. Hilbert’s and Thompson’s metrics. In this paper, a subset $C$ of a real vector space $X$ is called a cone (with vertex 0) if $tC := \{tx \mid x \in C\} \subset C$ for all $t \geq 0$. If $f$ is a map from a cone $C$ of a vector space $X$ to a cone $C'$ of a vector space $Y$, we shall say that $f$ is (positively) homogeneous (of degree 1) if $f(ty) = tf(y)$, for all $t > 0$ and $y \in C$. We say that the cone $C$ is pointed if $C \cap (-C) = \{0\}$. A convex pointed cone $C$ of $X$ induces on $X$ a partial ordering $\leq_C$, which is defined by $x \leq_C y$ if $y - x \in C$. If $C$ is obvious, we shall write $\leq$ instead of $\leq_C$. When $X$ is a topological vector space, we say that $C$ is proper if it is closed convex and pointed. Note that in [Nus88], a cone is by definition what we call here a proper cone. We next recall the definition of Hilbert’s and Thompson’s metrics associated to a proper cone $C$ of a topological vector space $X$. 

License or copyright restrictions may apply to redistribution; see https://www.ams.org/journal-terms-of-use
Let $x \in C \setminus \{0\}$ and $y \in X$. We define $M(y/x)$ by

$$M(y/x) := \inf\{b \in \mathbb{R} \mid y \leq bx\},$$

where the infimum of the emptyset is by definition equal to $+\infty$. Similarly, we define $m(y/x)$ by

$$m(y/x) := \sup\{a \in \mathbb{R} \mid ax \leq y\},$$

where the supremum of the emptyset is by definition equal to $-\infty$. We have $m(y/x) = -M(-y/x)$, and if in addition $y \in C \setminus \{0\}$, $m(y/x) = 1/M(x/y)$ (with $1/(+\infty) = 0$). Since $C$ is pointed and closed, we have $M(y/x) \in \mathbb{R} \cup \{+\infty\}$, and $y \leq M(y/x)x$ as soon as $M(y/x) < +\infty$. Symmetrically $m(y/x) \in \mathbb{R} \cup \{-\infty\}$ and $m(y/x)x \leq y$, as soon as $m(y/x) > -\infty$.

We shall say that two elements $x$ and $y$ in $C$ are **comparable** and write $x \sim y$ if there exist positive constants $a > 0$ and $b > 0$ such that $ax \leq y \leq bx$. If $x, y \in C \setminus \{0\}$ are comparable, we define

$$d(x, y) = \log M(y/x) - \log m(y/x),$$

$$\bar{d}(x, y) = \log M(y/x) \vee -\log m(y/x).$$

We also define $d(0, 0) = \bar{d}(0, 0) = 0$.

If $u \in C$, we define

$$C_u = \{x \in C \mid x \sim u\}.$$

If $C$ has nonempty interior int $C$, and $u \in \text{int} C$, then $C_u = \text{int} C$. To see this, take a neighborhood $V$ of 0 such that $u + V \subset C$. If $x \in \text{int} C$, we can find a neighborhood $W$ of 0 such that $x + W \subset C$. Let $a, b > 0$ be such that $-au \in W$ and $-bx \in W$. Then, $u - bx \in C$ and $x - au \in C$, and so $bx \leq u \leq a^{-1}x$, showing that $\text{int} C \subset C_u$. Conversely, if $x \in C_u$, we have $u \leq bx$ for some $b > 0$. It follows that $x + b^{-1}V = (x - b^{-1}u) + b^{-1}(u + V) \subset C + C = C$, showing that $x \in C$.

In general, $C_u \cup \{0\}$ is a pointed convex cone but $C_u \cup \{0\}$ is not closed. The map $d$ is a metric on $C_u$, called **Thompson’s metric**. The map $d$ is called **Hilbert’s projective metric** on $C_u$. The term “projective metric” is justified by the following properties: for all $x, y, z \in C_u$, $d(x, z) \leq d(x, y) + d(y, z)$, $d(x, y) = d(y, x) \geq 0$ and $d(x, y) = 0$ iff $y = \lambda x$ for some $\lambda > 0$.

From now, we will assume that $X = (X, \|\cdot\|)$ is a Banach space. We denote by $X^*$ the space of continuous linear forms over $X$, and by $C^* := \{\psi \in X^* \mid \psi(x) \geq 0 \ \forall x \in C\}$ the **dual cone** of $C$. If $f$ is a map between two ordered sets $(D, \leq)$ and $(D', \leq)$, we shall say that $f$ is **order preserving** if $f(x) \leq f(y)$ for all $x, y \in D$ such that $x \leq y$. Then, any element of $C^*$ is a homogeneous and order preserving map from $(X, \leq_C)$ to $[0, +\infty)$. Since $C$ is proper, the Hahn-Banach theorem implies that for all $u \in C \setminus \{0\}$, there exists $\psi \in C^*$ such that $\psi(u) > 0$. For such a $\psi$, we have $\psi(x) > 0$ for all $x \in C_u$. More generally, if $q : C_u \to (0, +\infty)$ is homogeneous and order preserving, we denote

$$\Sigma_u = \{x \in C_u \mid q(x) = q(u)\}.$$

Then, $d$ and $\bar{d}$ are equivalent metrics on $\Sigma_u$. Indeed, as shown in [Nus88, Remark 1.3, p. 15],

$$\frac{1}{2}d(x, y) \leq \bar{d}(x, y) \leq d(x, y), \ \forall x, y \in \Sigma_u.$$
More precisely:

\[(2.5) \quad 1 \leq M(y / x) \leq e^{d(x, y)} \quad \forall x, y \in \Sigma_u .\]

To see this, let us apply \( q \) to the inequality \( y \leq M(y / x) x \). Using the fact that \( q \) is order preserving and homogeneous, and that \( q(x) = q(y) \), we get \( M(y / x) \geq 1 \). By symmetry, \( M(x / y) \geq 1 \), hence \( \log M(y / x) = d(x, y) - \log M(x / y) \leq d(x, y) \).

We say that a cone \( C \) is normal if \( C \) is proper and there exists a constant \( M \) such that \( |x| \leq M\|y\| \) whenever \( 0 \leq x \leq y \). Every proper cone \( C \) in a finite dimensional Banach space \((X, \| \cdot \|)\) is necessarily normal. We shall need the following result of Thompson.

**Proposition 2.1** ([Tho63 Theorem 3]). Let \( C \) be a normal cone in a Banach space \((X, \| \cdot \|)\). For all \( u \in C \setminus \{0\} \), \((C_u, d)\) is a complete metric space.

The following result follows from a general result of Zabreiko, Krasnosel’skiı and Pokornyi [ZKP71] (see [Nus88 Theorem 1.2 and Remarks 1.1 and 1.3] and a previous result of Birkhoff [Bir62]). When \( q \in C^* \), it follows from Proposition 2.1 below and the property that \( \Sigma_u \) is closed in the topology of Thompson’s metric \( d \).

**Proposition 2.2.** Let \( C \) be a normal cone in a Banach space \((X, \| \cdot \|)\). Let \( u \in C \setminus \{0\} \) and \( q : C_u \to (0, +\infty) \), which is homogeneous and order preserving with respect to \( C \). Let \( \Sigma_u = \{x \in C_u \mid q(x) = 1\} \). Then, \((\Sigma_u, d)\) and \((\Sigma_u, d)\) are complete metric spaces.

### 2.2. The local Banach space \( X_u \).

Given \( u \in C \setminus \{0\} \), we define the linear space \( X_u = \{x \in X \mid \exists a > 0, -au \leq x \leq au\} \). We will show (in Lemma 2.3 and Proposition 2.4 below) that \( X_u \) is equipped with a norm \( \| \cdot \|_u \), and a seminorm \( \omega_u \), such that \( d \) and \( d \) behave locally, near \( u \), as \( \| \cdot \|_u \) and \( \omega_u \), respectively.

Let \( M \) and \( m \) be defined as in \((2.1)\) and \((2.2)\). We equip \( X_u \) with the norm

\[(2.6) \quad \|x\|_u = M(x / u) \vee -m(x / u) = \inf\{a > 0 \mid -au \leq x \leq au\} .\]

We also define the oscillation of \( x \) in \( X_u \):

\[(2.7) \quad \omega_u(x) = M(x / u) - m(x / u) = \inf\{b - a \mid au \leq x \leq bu\} .\]

The map \( \omega_u : x \mapsto \omega_u(x) \) is a seminorm on \( X_u \), which satisfies \( \omega_u(x) = 0 \iff x \in \mathbb{R}u \). Note also that \( \omega_u(x + au) = \omega_u(x) \) for all \( x \in X_u \) and \( a \in \mathbb{R} \). Since \( M(x / u) \vee -m(x / u) \geq \frac{1}{2}(M(x / u) - m(x / u)) \), we get

\[(2.8) \quad \frac{1}{2} \omega_u(x) \leq \|x\|_u , \quad \forall x \in X_u .\]

Moreover, when \( \psi \) is an element of \( C^* \) and \( \psi(u) = 1 \), \( \psi(x) = 0 \) and \( x \leq au \) implies \( 0 \leq a \), so that \( M(x / u) \geq 0 \), and dually, \( m(x / u) \leq 0 \). Hence, \( M(x / u) \vee -m(x / u) \leq M(x / u) - m(x / u) \), which gives

\[(2.9) \quad \|x\|_u \leq \omega_u(x) \quad \forall x \in X_u , \text{ such that } \psi(x) = 0 .\]

Gathering \((2.8)\) and \((2.9)\), we see that the restriction of \( \omega_u \) to the subspace \( \{x \in X_u \mid \psi(x) = 0\} \) of \( X_u \) is a norm equivalent to \( \| \cdot \|_u \).

We shall need the following variants or refinements of some inequalities of [Nus94 Proposition 1.1].
Lemma 2.3. Let $C$ be a proper cone, and $u \in C \setminus \{0\}$. For all $x, y \in C_u$, we have:

\begin{align}
\|x - y\|_u &\leq (e^{\bar{d}(x,y)} - 1)e^{\bar{d}(x,u)\wedge \bar{d}(y,u)}, \\
\bar{d}(x,y) &\leq \log(1 + \|x - y\|_u e^{\bar{d}(x,u)\vee \bar{d}(y,u)}) .
\end{align}

Moreover, defining $\Sigma_u$ as in (2.3), with $q := \psi \in C^*$ and $\psi(u) = 1$, we get that for all $x, y \in \Sigma_u$,

\begin{align}
\omega_u(x - y) &\leq (e^{\bar{d}(x,y)} - 1)e^{\bar{d}(x,u)\wedge \bar{d}(y,u)} , \\
d(x,y) &\leq \omega_u(x - y)e^{\bar{d}(x,u)\vee \bar{d}(y,u)} .
\end{align}

Proof. We first prove (2.10). By the definition of $\bar{d}$, we can write

\begin{align}
e^{-\bar{d}(y,u)}_u y &\leq e^{\bar{d}(y,u)}_u y , \\
e^{-\bar{d}(x,y)} y &\leq x \leq e^{\bar{d}(x,y)} y .
\end{align}

Using (2.15) and the second inequality in (2.14), we get

\begin{align}
(e^{-\bar{d}(x,y)} - 1)e^{\bar{d}(y,u)}_u y &\leq (e^{-\bar{d}(x,y)} - 1) y \\
&\leq x - y \leq (e^{\bar{d}(x,y)} - 1)y \leq (e^{\bar{d}(x,y)} - 1)e^{\bar{d}(y,u)}_u y .
\end{align}

Hence,

$$\|x - y\|_u \leq ((e^{\bar{d}(x,y)} - 1)\vee (1 - e^{-\bar{d}(x,y)}))e^{\bar{d}(y,u)} = (e^{\bar{d}(x,y)} - 1)e^{\bar{d}(y,u)} .$$

Together with the symmetrical inequality obtained by exchanging $x$ and $y$, this yields (2.10).

We next prove (2.11). By definition of $\| \cdot \|_u$, we can write

$$x - y \leq \|x - y\|_u u$$

for all $x, y \in X_u$. If $x, y \in C_u$, using the first inequality in (2.14), we deduce

$$x \leq y + \|x - y\|_u u \leq (1 + \|x - y\|_u e^{\bar{d}(y,u)})y ,$$

and by symmetry,

$$y \leq (1 + \|x - y\|_u e^{\bar{d}(x,u)})x .$$

It follows that

$$\bar{d}(x,y) \leq \log(1 + \|x - y\|_u e^{\bar{d}(y,u)}) \vee \log(1 + \|x - y\|_u e^{\bar{d}(x,u)}) = \log(1 + \|x - y\|_u e^{\bar{d}(y,u)\vee \bar{d}(x,u)}) ,$$

which shows (2.11).

We now prove (2.12). By the definition of $d$, we can write

\begin{align}
d(x,y) &\leq \log \frac{\beta}{\alpha} - \log \alpha , \text{ with } \alpha, \beta > 0 \\
\alpha y &\leq x \leq \beta y .
\end{align}

When $x, y \in \Sigma_u$, applying $\psi$ to (2.17), we get $\alpha \leq 1 \leq \beta$. Combining the second inequality in (2.17) with $\beta - 1 \geq 0$ and the second inequality in (2.14), we get

\begin{align}
x - y &\leq (\beta - 1)y \leq (\beta - 1)e^{\bar{d}(y,u)}_u .
\end{align}

Combining the first inequality in (2.17) with $\alpha - 1 \leq 0$ and the second inequality in (2.14), we get

\begin{align}
x - y &\geq (\alpha - 1)y \geq (\alpha - 1)e^{\bar{d}(y,u)}_u .
\end{align}
Gathering (2.18) and (2.19), we get
\[ \omega_u(x - y) \leq (\beta - \alpha)e^{\bar{d}(y,u)} . \]

By symmetry, \( \omega_u(x - y) \leq (\beta - \alpha)e^{\bar{d}(x,u)} \), so that
\[ \omega_u(x - y) \leq (\beta - \alpha)e^{d(x,y) \wedge \bar{d}(y,u)} . \]

Since \( \beta \geq 1 \geq \alpha \), we get
\[ \omega_u(x - y) \leq \left( \frac{\beta}{\alpha} - 1 \right)e^{\bar{d}(x,u) \wedge \bar{d}(y,u)} = (e^{d(x,y)} - 1)e^{\bar{d}(x,u) \wedge \bar{d}(y,u)} , \]
which shows (2.12).

We finally prove (2.13). By definition of \( \omega_u \), we have
\[ (2.20) \quad au \leq x - y \leq bu \]
for some \( a, b \in \mathbb{R} \), with \( b - a = \omega_u(x - y) \). Applying \( \psi \) to (2.20), we get \( a \leq 0 \leq b \).

Combining the second inequality in (2.20) with the first inequality in (2.14), we get
\[ (2.21) \quad x \leq y + bu \leq (1 + be^{\bar{d}(y,u)})y , \]
and by symmetry (2.20) is equivalent to \(-bu \leq y - x \leq -au\)
\[ (2.22) \quad y \leq x - au \leq (1 - ae^{d(x,u)})x . \]

Gathering (2.21) and (2.22), we get
\[ d(x,y) \leq \log(1 + be^{\bar{d}(y,u)}) + \log(1 - ae^{\bar{d}(x,u)}) . \]
Since \( \log(1 + x) \leq x \) for all \( x \geq 0 \) and \( b \geq 0 \geq a \), we get
\[ d(x,y) \leq be^{\bar{d}(y,u)} - ae^{d(x,u)} \leq (b - a)e^{d(x,u) \wedge \bar{d}(y,u)} , \]
which shows (2.13). \( \square \)

**Proposition 2.4.** Let \( C \) be a normal cone in a Banach space \((X, \| \cdot \|)\). Consider \( u \in C \setminus \{0\} \), and \( \psi \in C^* \) with \( \psi(u) > 0 \). Then \((X_u, \| \cdot \|_u)\) is a Banach space. Moreover, \( \| \cdot \|_u \) and \( \bar{d} \) induce the same topology on \( C_u \), and
\[ (2.23) \quad \| x - y \|_u \sim \bar{d}(x, y) \text{, when } x, y \to u \text{ in } (C_u, \bar{d}) , \]
where by (2.23), we mean that for all \( \lambda > 1 \), there exists a neighborhood \( U \) of \( u \) in \((C_u, \bar{d})\) such that
\[ \lambda^{-1}\bar{d}(x, y) \leq \| x - y \|_u \leq \lambda\bar{d}(x, y) \text{, for all } x, y \in U . \]

We also have
\[ (2.24) \quad \omega_u(x - y) \sim d(x, y) \text{, when } x, y \to u \text{ in } (\Sigma_u, \bar{d}) . \]

Also \( C \cap X_u \) is a normal cone in \((X_u, \| \cdot \|_u)\) and has nonempty interior given by \( C_u \). If \( C \) has nonempty interior in \((X, \| \cdot \|)\) and \( u \in \text{int } C \), then \( X_u = X \) and \( \| \cdot \| \) and \( \| \cdot \|_u \) are equivalent norms on \( X \).

**Proof.** It is proved in [Nus94] Proposition 1.1] that \( \| \cdot \|_u \) and \( \bar{d} \) induce the same topology on \( C_u \) (this indeed follows from (2.10) and (2.11)). The fact that \( X_u \) is a complete metric space when \( C \) is normal is a result of Zabreiko, Krasnosel’skiǐ, and Pokorny˘ı [ZKP71](see also Theorem 1.2 and Remark 1.1 in [Nus8]). This can also be derived from the completeness of \((C_u, \bar{d})\) (Proposition 2.1 above) and of the equivalence (2.23), which follows readily from (2.10) and (2.11). The equivalence (2.24) follows readily from (2.12) and (2.13). The fact that \( C \cap X_u \) is a normal
cone in \((X_u, \| \cdot \|_u)\) and has \(C_u\) as interior is remarked in [Nus94, Remark 1.1]. Indeed, since \(C\) is a proper cone and \(X_u\) is a vector space, \(C \cap X_u\) is a proper cone. Moreover, from (2.6), \(\| \cdot \|_u\) is order preserving on \(C \cap X_u\), hence \(C \cap X_u\) is normal. Also, by definition of \(C_u\) and (2.6), we get that \(C_u\) is open (if \(au \leq x \leq bu\) with \(a, b > 0\), then \(B(x, \epsilon) \subset C_u\) and equal to the interior of \(C \cap X_u\) if \(B(x, \epsilon) \subset C \cap X_u\), then \(eu \leq x \leq \|x\|_u u\) and \(x \in C_u\)). Finally, it is proved in [Nus94, Proposition 1.1] that \(\| \cdot \|_u\) and \(\| \cdot \|\) are equivalent norms on \(X = X_u\) when \(u\) is in the interior of \(C\).

We say that a cone \(C\) of a Banach space \((X, \| \cdot \|)\) is reproducing if \(X = C - C := \{x - y \mid x, y \in C\}\). It is known that a cone \(C\) in a Banach space \((X, \| \cdot \|)\) with nonempty interior is reproducing (see for instance [AGN11, Proposition 2.4]).

Remark 2.5. It is shown in [Nus94] that Thompson’s metric coincides with the Finsler metric arising when considering the interior of the cone \(C\) as a manifold and equipping the tangent space at point \(u\) with the local norm \(\| \cdot \|_u\). Hilbert’s metric arises in a similar way, when equipping the tangent space with the seminorm \(\omega_u\).

2.3. AM-spaces with units. Recall that an ordered set \((X, \leq)\) is a sup-semilattice (resp. inf-semilattice) if any nonempty finite subset \(F\) of \(X\) admits a least upper bound (resp. greatest lower bound) in \(X\), denoted \(\vee F\) (resp. \(\wedge F\)). We shall also use the infix notation \(x \vee y = \vee\{x, y\}\) and \(x \wedge y = \wedge\{x, y\}\). We say that \(X\) is a lattice when it is both a sup-semilattice and an inf-semilattice. A Banach lattice is a Banach space \((X, \| \cdot \|)\) equipped with an order relation, \(\leq\), such that \((X, \leq)\) is a lattice, \(x \leq y \Rightarrow x + z \leq y + z\) and \(\lambda x \leq \lambda y\), for all \(x, y, z \in X\) and \(\lambda \geq 0\), and \(|x| \leq |y| \Rightarrow \|x\| \leq \|y\|\), for all \(x, y \in X\), where \(|x| := x \vee (-x)\). Note that if \(X\) is a Banach lattice, then the lattice operations are continuous in the norm topology [MN91] Prop. 1.1.6. Moreover, \(X^+ := \{x \in X \mid 0 \leq x\}\) is closed and it is a reproducing normal cone. An AM-space with unit is a Banach lattice \((X, \| \cdot \|)\) such that \(\|x \vee y\| = \|x\| \vee \|y\|\) for all \(x, y \in X^+\), and such that the closed unit ball of \(X\) has a maximal element \(e\), which is called the unit (see for instance [Sch74] or [AB99] for definitions and results about AM-spaces). Equivalently, \(X\) is an AM-space with unit, if \(X\) is a Banach lattice equipped with a distinguished element \(e \geq 0\) (the unit), which is such that \(\|x\| = \inf\{a \geq 0 \mid -ae \leq x \leq ae\}\) (see [AB99] Section 8.4; note however that in this reference, a slightly different definition of a unit is used, but it is shown that there exists another norm equivalent to \(\| \cdot \|\) satisfying all the above conditions). The fundamental example of an AM-space with unit is given by the space \(\mathcal{C}(K)\) of continuous functions on a compact set \(K\), equipped with the sup-norm \(\| \cdot \|_\infty\), the pointwise order \(\leq\) and the unit \(1\), where \(1\) is the constant function \(K \to \mathbb{R}\), \(t \mapsto 1\). In fact, the Kakutani-Krein theorem ([AB99, Theorem 8.29] or [Sch74, Chapter II, Theorem 7.4]) shows that an AM-space with unit is isomorphic as an AM-space with unit (that is lattice isomorphic and isometric) to \(\mathcal{C}(K)\), for some compact, Hausdorff set \(K\).

Any AM-space with unit \(X\) can be put in isometric correspondence with the interior of a normal cone equipped with Thompson’s metric, thanks to the following construction. Let \(\iota : X \to \mathcal{C}(K)\) be the isomorphism (of AM-spaces with unit, where \(K\) is a compact set) given by the Kakutani-Krein theorem. Consider \(C = \mathcal{C}^+(K)\) the set of nonnegative continuous functions on \(K\). Then, \(C\) is a normal cone, and the order \(\leq_C\) associated to \(C\) is nothing but the pointwise order in \(\mathcal{C}(K)\).
The interior \( \text{int} \ C \) of \( C \) is the set of continuous functions \( K \to \mathbb{R} \) that are bounded from below by a positive constant, or equivalently (since \( K \) is compact), the set of continuous functions \( K \to \mathbb{R} \) that are positive everywhere. Consider the map 
\[
\log : \text{int} \ C \to \mathcal{C}(K),
\]
which sends the continuous positive map \( t \in K \to y(t) \) to the continuous map \( t \in K \to \log y(t) \), and denote by \( \exp = \log^{-1} \) its inverse. Then, the map \( \exp^{-1} \circ \log : \text{int} \ C \to X \) is an isometry between \( \text{int} \ C \) endowed with Thompson’s metric and \( X \) endowed with the distance associated with the norm \( \| \cdot \| \).

3. Semidifferentiable maps

In this section, we consider (with a slight modification) the notion of semidifferentiability introduced by Penot in [Pen82] in the case of maps defined on Banach spaces. We also refer the reader to [RW98] for the case of maps defined on \( \mathbb{R}^n \). Here we establish some properties of semidifferentiable maps defined on normed vector spaces, which will be needed in the proof of the main results and in the applications.

3.1. Semidifferentiable maps on normed vector spaces. Let \( (X, \| \cdot \|) \) and \( (Y, \| \cdot \|) \) be normed vector spaces, \( G \) be a subset of \( X \), and \( v \in G \). Recall that a map \( h \) from a cone \( C \) of \( X \) to \( Y \) is homogeneous if \( f(ty) = tf(y) \), for all \( t > 0 \) and \( y \in C \). We say that a map \( f : G \to Y \) is semidifferentiable at \( v \) with respect to a cone \( C \subset X \) if \( G \) contains a neighborhood of \( v \) in \( v + C := \{ v + x \mid x \in C \} \) (that is, if there exists \( \epsilon > 0 \) such that all the elements of the form \( v + x \) with \( x \in C \) and \( \|x\| \leq \epsilon \) belong to \( G \)), and if there exists a continuous (positively) homogeneous map \( h : C \to Y \) such that

\[
f(v + x) = f(v) + h(x) + o(\|x\|), \quad \text{when } x \to 0, \ x \in C.
\]

If \( C = X \) (and \( v \) is in the interior of \( G \)), we say for short that \( f \) is semidifferentiable at \( v \). The map \( h \), if it exists, is unique, since then, for all \( x \in C \), the classical (one sided) directional derivative

\[
f'_{v}(x) := \lim_{t \to 0^{+}} \frac{f(v + tx) - f(v)}{t}
\]

exists and coincides with \( h(x) \). In fact, the definition (3.2) of directional derivatives is obtained by specializing (3.1) to a cone of the form \( C = \{ tx \mid t \geq 0 \} \), and the classical definition of Frechet derivatives is obtained by specializing (3.1) to \( C = X \), and requiring \( h \) to be linear. We call \( h \) the semidifferential of \( f \) at \( v \) with respect to \( C \), and we denote it by \( f'_{v} \). Note that in general the set \( D \) of \( x \in X \) such that \( f'_{v}(x) \) exists is a cone which may contain strictly \( C \), for the map \( h : D \to Y, \ x \mapsto f'_{v}(x) \) is not necessarily continuous on \( D \) or it does not satisfy equation (3.1) on \( D \). However we shall only use the notation \( f'_{v} \) for the restriction of \( x \mapsto f'_{v}(x) \) to a cone \( C \) satisfying the above conditions.

The following characterization of semidifferentiable maps, which is a mere rephrasing of property (3.1), illuminates the requirements that semidifferentiability adds to the existence of directional derivatives.

**Lemma 3.1.** Let \( (X, \| \cdot \|) \) and \( (Y, \| \cdot \|) \) be normed vector spaces, \( G \) be a subset of \( X \), \( v \in G \), and \( C \) be a cone of \( X \) such that \( G \) contains a neighborhood of \( v \) in \( v + C \). Then, a map \( f : G \to Y \) is semidifferentiable at \( v \) with respect to \( C \) if, and
only if,
\begin{align}
\frac{f(v + tx) - f(v)}{t} &\to f'_v(x) \text{ when } t \to 0^+, \\
\text{uniformly for } x \text{ in bounded sets of } C,
\end{align}
and the map \( C \to Y, x \mapsto f'_v(x) \) is continuous.

The following lemma shows in particular that when \( f \) is locally Lipschitz continuous and \( X \) is finite dimensional, the last two properties are implied by the existence of directional derivatives.

**Lemma 3.2.** Let \((X, \| \cdot \|)\) and \((Y, \| \cdot \|)\) be normed vector spaces, \( G \) be a subset of \( X \), \( v \in G \), and \( C \) be a cone of \( X \) such that \( G \) contains a neighborhood of \( v \) in \( v + C \). Assume that \( f : G \to Y \) is Lipschitz continuous in a neighborhood of \( v \), and that \( f \) has directional derivatives \( f'_v(x) \) at \( v \) with respect to all \( x \in C \). Then \( C \to Y, x \mapsto f'_v(x) \) is Lipschitz continuous with the same Lipschitz constant as \( f \). Moreover,
\begin{align}
\frac{f(v + tx) - f(v)}{t} &\to f'_v(x) \text{ when } t \to 0^+, \\
\text{uniformly for } x \text{ in compact sets of } C,
\end{align}

and
\[ \lim_{x' \to x, \, x' \in C} \frac{f(v + tx') - f(v)}{t} = f'_v(x) \quad \forall x \in C. \]

In particular, if \( X \) is finite dimensional and \( C \) is closed in \( X \), then \( f \) is semidifferentiable at \( v \) with respect to \( C \).

**Proof.** Since \( G \) contains a neighborhood of \( v \) in \( v + C \) and \( f \) is Lipschitz continuous in a neighborhood of \( v \), we can find \( \epsilon > 0 \) and \( M \geq 0 \) such that
\[ (z, z' \in C \text{ and } \|z\|, \|z'\| \leq \epsilon) \implies \|f(v + z) - f(v + z')\| \leq M\|z - z'\|. \]

Let \( K \) denote a compact subset of \( C \), let \( R = \max\{\|x\| \mid x \in K\} \), and, for \( 0 < t \leq R^{-1}\epsilon \), consider the map \( g_{v,t} : K \to Y \),
\[ g_{v,t}(x) = \frac{f(v + tx) - f(v)}{t}. \]

For all \( x, x' \in K \) and \( 0 < t \leq R^{-1}\epsilon \), we have
\[ \|g_{v,t}(x) - g_{v,t}(x')\| \leq M\|x - x'\|. \]

The family \( \{g_{v,t}\}_{0 < t \leq R^{-1}\epsilon} \) is an equicontinuous family of maps converging pointwise to the map \( K \to Y, x \mapsto f'_v(x) \). Hence for all \( x \in K \), the set \( \{g_{v,t}(x) \mid 0 < t \leq R^{-1}\epsilon\} \) is relatively compact. This implies, by Ascoli’s theorem, that \( g_{v,t}(x) \) converges to \( f'_v(x) \) as \( t \to 0^+ \), uniformly in \( x \in K \), which shows (3.4). Of course, by (3.6), \( x \mapsto f'_v(x) \) is \( M \)-Lipschitz on \( K \), and since this holds for all compact subsets \( K \subset C \), \( x \mapsto f'_v(x) \) is \( M \)-Lipschitz on \( C \). Finally, to prove (3.5), it is enough to show that
\[ \lim_{k \to \infty} \frac{f(v + tkx_k) - f(v)}{t_k} = f'_v(x). \]
holds for all sequences \( \{x_k\}_{k \geq 1} \), \( x_k \in C \), \( x_k \to x \), and \( \{t_k\}_{k \geq 1} \), \( t_k > 0 \), \( t_k \to 0 \).
Since \( \{x_k \mid k \geq 1\} \cup \{x\} \) is compact, it follows from \((3.2)\) that
\[
\lim_{k \to \infty} \left( \frac{f(v + t_kx_k) - f(v)}{t_k} - f'_v(x_k) \right) = 0.
\]

Since \( x \mapsto f'_v(x) \) is continuous on \( C \), \( f'_v(x_k) \to f'_v(x) \), and we get \((3.5)\). \( \square \)

Remark 3.3. When \( G = X = C = \mathbb{R}^n \) and \( Y = \mathbb{R} \), Rockafellar and Wets [RW98, Chap. 7, §D] define semidifferentiable maps \( f : \mathbb{R}^n \to \mathbb{R} \) at \( v \) by requiring that \((3.5)\) holds, for all \( x \in \mathbb{R}^n \). Assume now that \( X \) and \( Y \) are arbitrary normed vector spaces, that \( C \subset X \) is a cone, that \( G \subset X \), and that \( f : G \to X \). Then \((3.5)\) holds if, and only if, \( x \mapsto f'_v(x) \) is continuous and satisfies \((3.4)\). (Indeed, we showed the “if” part in the proof of Lemma 3.2, and the “only if” part of the result is not difficult.) This equivalence is a special case of a general property, saying that a sequence of functions \( f_n \) (defined on a metric space \( X \)) converges continuously to a function \( f \), i.e., satisfies \( f_n(x_n) \to f(x) \), for all convergent sequences \( x_n \to x \); if, and only if, \( f_n \) converges to \( f \) uniformly on compact sets and \( f \) is continuous, see [RW98, Theorem 7.14]. (The theorem of [RW98] is stated when \( X = \mathbb{R}^n \) and \( Y = \mathbb{R} \), but the property holds for arbitrary metric spaces \( X \) and \( Y \).) When \( X = C = \mathbb{R}^n \) (and \( Y = \mathbb{R} \), Rockafellar and Wets show that \((3.5)\) is equivalent to \((3.1)\) [RW98, Theorem 7.21], so that our definition of semidifferentiable maps is consistent with the one of [RW98]. By comparing \((3.3)\), which is equivalent to \((3.1)\), with \((3.4)\) together with the requirement that \( x \mapsto f'_v(x) \) is continuous, which is equivalent to \((3.5)\), we see that for general normed vector spaces, our definition \((3.1)\) of semidifferentiable maps becomes stronger than the one we would obtain by taking the definition \((3.5)\) of [RW98].

We shall need the notion of a norm of a continuous homogeneous map \( h \) from a cone \( C \) of a normed vector space \( (X, \| \cdot \|) \) to a normed vector space \( (Y, \| \cdot \|) \):
\[
(3.7)\quad \|h\|_C := \sup_{x \in C \setminus \{0\}} \frac{\|h(x)\|}{\|x\|} < +\infty.
\]
When \( C \) is obvious, and in particular when \( C = X \), we will simply write \( \|h\| \) instead of \( \|h\|_C \). Since \( h(0) = 0 \) and \( h \) is continuous, there exists \( \delta > 0 \) such that \( \|h(x)\| \leq 1 \) for all \( x \in C \) such that \( \|x\| \leq \delta \). Hence, by homogeneity of \( h \), \( \|h\|_C \leq 1/\delta < +\infty \), as claimed in \((3.7)\). In particular, when \( f \) is semidifferentiable at \( v \) with respect to \( C \), there exists \( \gamma > 0 \) such that
\[
(3.8)\quad \|f'_v(x)\| \leq \gamma \|x\| \quad \forall x \in C,
\]
since by definition, \( f'_v \) is homogeneous and continuous. When \( f'_v \) is a linear map on \( X \), that is, when \( f \) is differentiable, \((3.8)\) implies that \( f'_v \) is Lipschitz continuous. Another condition which guarantees the Lipschitz continuity of \( f'_v \) was given in Lemma 3.2.

We next prove a chain rule for semidifferentiable maps:

Lemma 3.4 (Chain rule). Let \( (X, \| \cdot \|) \), \( (Y, \| \cdot \|) \) and \( (Z, \| \cdot \|) \) be normed vector spaces, let \( G_1 \) and \( G_2 \) be subsets of \( X \) and \( Y \) respectively, let \( f : G_1 \to Y \), \( g : G_2 \to Z \) be two maps such that \( f(G_1) \subset G_2 \), and let \( v \in G_1 \). Assume that
\begin{align*}
(\text{A1}) \quad & f \text{ is semidifferentiable at } v \text{ with respect to a cone } C_1; \\
(\text{A2}) \quad & g \text{ is semidifferentiable at } f(v) \text{ with respect to a cone } C_2; \\
(\text{A3}) \quad & f'_v(C_1) \subset C_2 \text{ and } f(G_1 \cap (v + C_1)) \subset f(v) + C_2;
\end{align*}

License or copyright restrictions may apply to redistribution; see https://www.ams.org/journal-terms-of-use
(A4) $g'_{f(v)}$ is uniformly continuous on bounded sets of $C_2$.

Then, $g \circ f : G_1 \to Z$ is semidifferentiable at $v$ with respect to $C_1$, and

$$(g \circ f)'_v = g'_{f(v)} \circ f'_v.$$ 

Proof. Using assumptions [(A1)] and [(A2)], we can write:

\begin{align}
(3.9) & \quad f(v + x) = f(v) + f'_v(x) + \|x\|\epsilon_1(x), \\
(3.10) & \quad g(f(v + y)) = g(f(v)) + g'_{f(v)}(y) + \|y\|\epsilon_2(y),
\end{align}

where $\epsilon_1$ (resp. $\epsilon_2$) is a map defined on a neighborhood of 0 in $C_1$ (resp. $C_2$), with $\epsilon_1(x) \to 0$ when $\|x\| \to 0$ (resp. $\epsilon_2(y) \to 0$ when $\|y\| \to 0$). Using (3.9), (3.10), and assumption [(A3)], we get

\begin{align}
(3.11) & \quad g \circ f(v + x) = g \circ f(v) + g'_{f(v)}(f'_v(x) + \|x\|\epsilon_1(x)) + \eta(x),
\end{align}

where $\eta(x) = \|f'_v(x) + \|x\|\epsilon_1(x)\|\epsilon_2(f'_v(x) + \|x\|\epsilon_1(x))$. Using (3.8), we can write

\begin{align}
(3.12) & \quad \eta(x) = \|x\|\epsilon_3(x),
\end{align}

where $\epsilon_3$ is a map defined on a neighborhood of 0 in $C_1$, such that $\epsilon_3(x) \to 0$ when $\|x\| \to 0$. Using the homogeneity of $g'_{f(v)}$ and $f'_v$, we get:

\begin{align*}
\epsilon_4(x) & = \|f'_v(x) + \|x\|\epsilon_1(x)\| - \|x\|g'_{f(v)}(\|x\|^{-1}x + \epsilon_1(x))
\end{align*}

Hence, the uniform continuity assumption for $g'_{f(v)}$ (assumption [(A4)] implies that there is a map $\epsilon_4$ defined on a neighborhood of 0 in $C_1$ such that

\begin{align}
(3.13) & \quad g'_{f(v)}(f'_v(x) + \|x\|\epsilon_1(x)) = \|x\|g'_{f(v)}(\|x\|^{-1}x + \epsilon_1(x))
\end{align}

with $\epsilon_4(x) \to 0$ when $\|x\| \to 0$. Gathering (3.11), (3.12), and (3.13), we get

$$g \circ f(v + x) = g'_{f(v)} \circ f'_v(x) + \|x\|\epsilon_5(x),$$

where $\epsilon_5 = \epsilon_3 + \epsilon_4$, which concludes the proof of the lemma. \hfill \square

Remark 3.5. When $C_2$ is closed, assumption [(A3)] reduces to the condition

$$f(G_1 \cap (v + C_1)) \subset f(v) + C_2.$$ 

Also, in this condition, $G_1$ can be replaced by a neighborhood of $v$ in $G_1$.

Remark 3.6. By homogeneity of $g'_{f(v)}$, assumption [(A4)] of Lemma 3.4 is equivalent to the uniform continuity of $g'_{f(v)}$ on the intersection of $C_2$ with the unit ball of $Y$.

Remark 3.7. Since a continuous map on a compact subset of a metric space is uniformly continuous, assumption [(A4)] of Lemma 3.4 automatically holds when $C_2$ is closed and $Y$ is finite dimensional. Therefore, Lemma 3.4 extends the result stated in [RW98, Exercise 10.27,(b)] in the case of finite dimensional vector spaces.
Semidifferentiability of sups. In applications to control and game theory, one needs to consider maps from $\mathbb{R}^n$ to $\mathbb{R}$ of the form

$$f = \sup_{a \in A} f_a,$$

where $(f_a)_{a \in A}$ is a family of maps $\mathbb{R}^n \to \mathbb{R}$, and the supremum is taken for the pointwise ordering of functions. Dually, $f$ may be defined as the infimum of a family of maps.

We next give conditions which guarantee that a map of the form (3.14) has directional derivatives or that it is semidifferentiable. Recall that a real valued map $g : A \to \mathbb{R}$ is upper-semicontinuous (resp. sup-compact) if for all $\lambda \in \mathbb{R}$, the upper level set $S_\lambda(g) = \{a \in A \mid g(a) \geq \lambda\}$ is closed (resp. compact). The following theorem gives a general version, for semidifferentiable maps, of the rule of “differentiation” of a supremum, which has appeared in the literature in various guises; see Remarks 3.12, 3.14 below.

**Theorem 3.8.** Let $X$ denote a normed vector space, let $v, x \in X$, let $V$ denote a neighborhood of $v$, and let $f : V \to \mathbb{R}$ be given by (3.14), where $(f_a)_{a \in A}$ is a family of maps $V \to \mathbb{R}$ and $A$ is a Hausdorff topological space. Make the following assumptions:

(A1) There exists $b \in A$ such that $f(v) = f_b(v)$.

(A2) For all $a \in A$, the directional derivative of $f$ at $v$ in the direction $x$, $(f_a)'_v(x)$, exists.

(A3) The maps $a \mapsto f_a(v)$ and $a \mapsto (f_a)'_v(x)$ are upper-semicontinuous.

(A4) There exists a real number $t_0 > 0$ such that the map

$$a \mapsto f_a(v) + t_0 (f_a)'_v(x)$$

is sup-compact.

(A5) We have

$$f_a(v + tx) \leq f_a(v) + t (f_a)'_v(x) + t \varepsilon_x(t) \quad \forall a \in A \forall t \in [0, t_1],$$

for some $t_1 > 0$ and some function $\varepsilon_x : [0, t_1] \to \mathbb{R}$ independent of $a$, such that $\varepsilon_x(t) \to 0$ when $t \to 0^+$.

Then, the directional derivative of $f$ at $v$ in the direction $x$ exists, and

$$f'_v(x) = \max_{a \in A, f_a(v) = f(v)} (f_a)'_v(x).$$

Moreover, if the previous assumptions are satisfied for all $x \in X$, if $X$ is finite dimensional and if $f$ is Lipschitz continuous in a neighborhood of $v$, then $f$ is semidifferentiable at point $v$.

We shall see in Remarks 3.13–3.14 below that assumptions (A2), (A5) or (A4) are implied by several standard assumptions, and that Theorem 3.8 extends several known results.

Before proving Theorem 3.8 we make the following observation.

**Lemma 3.9.** Let (A4) and (A3) be as in Theorem 3.8. If assumption (A4) is satisfied for some $t_0 > 0$, and if assumption (A3) is satisfied, then assumption (A4) is still satisfied if we replace $t_0$ by any $t \in (0, t_0)$. 

License or copyright restrictions may apply to redistribution; see https://www.ams.org/journal-terms-of-use
Proof. We first remark that if \( g, h \) are two maps \( A \to \mathbb{R} \), such that \( g \) is sup-compact, \( h \) is upper-semicontinuous, and \( h \leq g \), then \( h \) is also sup-compact. Indeed, for all \( \lambda \in \mathbb{R} \), \( S_\lambda(h) \) is included in \( S_\lambda(g) \), \( S_\lambda(h) \) is closed since \( h \) is upper-semicontinuous, and \( S_\lambda(g) \) is compact because \( g \) is sup-compact, and thus, \( S_\lambda(h) \) is compact.

Consider now \( h_0: a \mapsto f_a(v) + t_0(f_a)'(x) \). By assumption (A4), \( h_0 \) is sup-compact. Take \( t \in (0, t_0) \), and define \( h_1: a \mapsto f_a(v) + t(f_a)'(x) \), which is upper-semicontinuous thanks to assumption (A3). We have \( h_1(a) = \frac{1}{t_0}h_0(a) + (1 - \frac{1}{t_0})f_a(v) \leq \frac{1}{t_0}h_0(a) + (1 - \frac{1}{t_0})f(v) \), which shows that \( h_1 \) is bounded from above by a sup-compact map. Thus, \( h_1 \) is sup-compact. 

Proof of Theorem 3.8 The first part of the theorem is a property of the one real variable functions \( g(t) = f(v + tx) \) and \( g_a(t) = f_a(v + tx) \), that is, one can assume without loss of generality that \( X = \mathbb{R} \), \( v = 0 \) and \( x = 1 \), \( g = f \) and \( g_a = f_a \), and omit \( x \) when possible.

By assumption (A5) we have for all \( t \in (0, t_1] \) and for all \( a \in A \),

\[
g_a(t) - g(0) \overline{\leq} \frac{g_a(t) - g_a(0) + g_a(0) - g(0)}{t} \leq h_a(t) + \epsilon(t) ,
\]

where

\[
h_a(t) := \frac{t(g_a)'(1) + g_a(0) - g(0)}{t} .
\]

Taking the sup of the inequalities (3.16), we get

\[
\frac{g(t) - g(0)}{t} \leq \sup_{a \in A} h_a(t) + \epsilon(t) .
\]

Since \( g_a(0) \leq g(0) \), \( h_a(t) \) is a nondecreasing function of \( t \), so that

\[
\lim_{t \to 0^+} \sup_{t \in (0, t_0)} \frac{g(t) - g(0)}{t} \leq \lim_{t \to 0^+} \sup_{a \in A} h_a(t) + \epsilon(t) = \inf_{t > 0} \sup_{a \in A} h_a(t) .
\]

For all \( t \in (0, t_0) \), the map \( a \mapsto h_a(t) \), which is sup-compact by Lemma 3.9, attains its sup at some point \( a_t \in A \). Let \( \lambda \) denote the value of the right hand side of (3.17). We have, \( h_{a_t}(t) \geq \lambda \), so that the upper level set \( S_{\lambda}(a \mapsto h_{a_t}(t)) \) is nonempty. Since a nonincreasing intersection of nonempty compact sets is nonempty, we can find \( c \in \bigcap_{t \in (0, t_0)} S_{\lambda}(a \mapsto h_{a_t}(t)) \). Then, for all \( t \in (0, t_0) \),

\[
\frac{t(g_c)'(1) + g_c(0) - g(0)}{t} = (g_c)'(1) + \frac{g_c(0) - g(0)}{t} \geq \lambda .
\]

Observe that \( \lambda \) is finite, because \( \lambda \geq (g_a)'(1) \) with \( g_a(0) = g(0) \) as in assumption (A1). Thus, multiplying (3.18) by \( t \) and letting \( t \to 0^+ \), we get \( g_c(0) - g(0) \geq 0 \), and since the other inequality is obvious, \( g_c(0) = g(0) \), which shows that \( c \in \{ a \in A \mid g_a(0) = g(0) \} \). Combining (3.18) and (3.17), we get

\[
\lim_{t \to 0^+} \sup_{a \in A} \frac{g(t) - g(0)}{t} \leq \inf_{t > 0} \sup_{a \in A} h_a(t) = \lambda \leq (g_c)'(1) \leq \sup_{a: g_a(0) = g(0)} (g_a)'(1) .
\]

Conversely, for all \( a \) such that \( g_a(0) = g(0) \), we have \( g(t) - g(0) = g(t) - g_a(0) \geq g_a(t) - g_a(0) \), since \( g \geq g_a \), so that

\[
\lim_{t \to 0^+} \frac{g(t) - g(0)}{t} \geq \lim_{t \to 0^+} \frac{g_a(t) - g_a(0)}{t} = (g_a)'(1) .
\]
Thus,

\[(3.20) \quad \liminf_{t \to 0^+} \frac{g(t) - g(0)}{t} \geq \sup_{a \in A, \, g_a(0) = g(0)} (g_a)'(0) .\]

Gathering (3.19) and (3.20), we get that the directional derivative of \( f \) at \( v \) in the direction \( x, f'_a(x) \), exists, is finite, and is given by (3.15). Moreover, the sup in (3.15) is a max since it is attained by taking \( a = b \).

Now the last assertion of Theorem 3.8 follows from Lemma 3.2. \( \square \)

**Remark 3.10.** Assumption (A4) is implied by standard assumptions.

First, if \( a \mapsto (f_a)'(x) \) is sup-compact, then assumption (A4) follows from assumption (A3). Indeed, for all \( t_0 > 0 \), \( f_a(v) + t_0(f_a)'(x) \leq f(v) + t_0(f_a)'(x) \). Hence, \( a \mapsto f_a(v) + t_0(f_a)'(x) \) is sup-compact since it is upper-semicontinuous and bounded from above by a sup-compact map.

Symmetrically, if \( a \mapsto f_a(v) \) is sup-compact and \( a \mapsto (f_a)'(x) \) is upper-semicontinuous and bounded from above, then again assumption (A4) is satisfied for all \( t_0 > 0 \), since \( f_a(v) + t_0(f_a)'(x) \leq f_a(v) + t_0 \lambda \) for some \( \lambda \in \mathbb{R} \).

Other assumptions which imply assumption (A4) are the following. Assume that \( a \mapsto f_a(v) \) is sup-compact, that assumption (A3) is satisfied, and that \( a \mapsto f_a(v) + t_1(f_a)'(x) \) is bounded from above, for some \( t_1 > 0 \). Then, we claim that \( a \mapsto f_a(v) + t_0(f_a)'(x) \) is sup-compact, for all \( t_0 \in (0, t_1) \). Indeed, let \( \lambda = \sup_{a \in A} f_a(v) + t_1(f_a)'(x) \). Then, \( f_a(v) + t_0(f_a)'(x) = \left( 1 - \frac{t_0}{t_1} \right) f_a(v) + \frac{t_0}{t_1} (f_a(v) + t_1(f_a)'(x)) \leq \left( 1 - \frac{t_0}{t_1} \right) f_a(v) + \frac{t_0}{t_1} \lambda \), and since an upper-semicontinuous map bounded from above by a sup-compact map is sup-compact, the claim is proved.

**Remark 3.11.** If \( X = \mathbb{R}^n \), and if for all \( a \in A \), \( f_a : x \mapsto p_a \cdot x + r_a \) for some \( p_a \in \mathbb{R}^n \) and \( r_a \in \mathbb{R} \), then \( f_a \) is affine, thus it is differentiable at any \( v \in \mathbb{R}^n \) with \( (f_a)'(x) = p_a \cdot x \) for all \( x \in \mathbb{R}^n \). Hence, \( f \) is convex, assumption (A2) is satisfied, assumption (A5) is satisfied with \( \epsilon = 0 \) and formula (3.15) becomes

\[ f_a'(x) = \max_{a \in A, \, f_a(v) = f(v)} p_a \cdot x . \]

Assumption (A3) is satisfied when \( a \mapsto p_a \) is continuous and \( a \mapsto r_a \) is upper-semicontinuous. Finally, assumption (A4) is satisfied if, and only if, \( a \mapsto f_a(v + t_0 x) \) is sup-compact. These assumptions are thus satisfied for instance when \( a \mapsto r_a \) is sup-compact and \( a \mapsto p_a \) is bounded and continuous.

**Remark 3.12.** From Remark 3.11 one can see that Theorem 3.8 extends the classical rule for the directional derivative of a convex function. When \( f : \mathbb{R}^n \to \mathbb{R} \cup \{+\infty\} \) is convex, we can write, by Legendre-Fenchel duality [Roc70, Th. 12.2],

\[ f(x) = \sup_{p \in \text{dom } f^*} p \cdot x - f^*(p) , \]

where \( f^*(p) = \sup_{x \in \mathbb{R}^n} p \cdot x - f(x) \) denotes the Legendre-Fenchel transform of \( f \), evaluated at \( p \in \mathbb{R}^n \), and for any map \( g : \mathbb{R}^n \to \mathbb{R} \cup \{+\infty\} \), \( \text{dom } g = \{ x \in \mathbb{R}^n \mid g(x) < \infty \} \) denotes the effective domain of \( g \). So, the restriction of \( f \) to dom \( f \) can be written as (3.14) with \( A = \text{dom } f^* \), \( a = p \), and \( f_a(x) = f_p(x) = p \cdot x - f^*(p) \). Let us denote by \( V \) the interior of \( \text{dom } f \), and assume that \( v \in V \). Assumption (A1) is satisfied, because \( f(v) = p \cdot v - f^*(p) = f_p(v) \) holds for all \( p \) in the subdifferential \( \partial f(v) \) of \( f \) at \( v \), and \( \partial f(v) \) is nonempty because \( f \) is convex and \( v \) is in \( V \) (see again [Roc70, Th. 23.4]). We are in the conditions of Remark 3.11 with \( p_a = a \).
and \( r_a = -f^*(a) \). Hence, assumptions \([\text{A2}]\) and \([\text{A5}]\) are satisfied. Since \( a \mapsto p_a \) is continuous and \( a \mapsto r_a \) is upper-semicontinuous, assumption \([\text{A3}]\) is satisfied. Moreover, assumption \([\text{A4}]\) is satisfied since for any \( w \in V \), \( a \mapsto f_a(w) \) is sup-compact, and since \( v + t_0x \in V \) when \( v \in V \), \( x \in \mathbb{R}^n \) and \( t_0 > 0 \) is small enough. Indeed, \( f_p(w) = p \cdot w - f^*(p) = p \cdot w - \sup_{x \in \mathbb{R}^n} (p \cdot x - f(x)) \leq p \cdot (w - x) + f(x) \), for all \( x \in \mathbb{R}^n \). Taking \( \epsilon > 0 \) and \( x = w + \epsilon \frac{p}{\|p\|} \), we get \( f_p(w) \leq -\epsilon p \cdot \frac{p}{\|p\|} + f(w + \epsilon \frac{p}{\|p\|}) = -\epsilon \|p\| + f(w + \epsilon \frac{p}{\|p\|}) \). Since \( f \) is convex and \( w \in V \), \( f \) is continuous on a neighborhood of \( w \) \([\text{Roc70}]\) Th. 10.1, and thus for \( \epsilon > 0 \) small enough \( f(w + \epsilon \frac{p}{\|p\|}) \) can be bounded independently of \( p \), which implies that the upper level sets of \( p \mapsto f_p(w) \) are bounded. Since these level sets are closed subsets of \( \mathbb{R}^n \), they are compact, so \( p \mapsto f_p(w) \) is sup-compact. Hence all the assumptions of Theorem 3.8 are satisfied. Finally, formula (3.15) becomes

\[
f_v'(x) = \max_{p \in \partial f(v)} p \cdot x,
\]

which coincides with the classical formula of Theorem 23.4 of \([\text{Roc70}]\).

**Remark 3.13.** When, in Theorem 3.8, \( X = \mathbb{R}^n \), and \( f_a : V \to \mathbb{R} \) is concave, the directional derivative

\[
(f_a)'_v(x) = \lim_{t \to 0^+} \frac{f_a(v + tx) - f_a(v)}{t}
= \sup_{t > 0} \frac{f_a(v + tx) - f_a(v)}{t}
\]

exists and is finite \([\text{Roc70}]\) Th. 23.1 and 23.4 (see also Remark 3.12), so that assumption \([\text{A2}]\) is satisfied. Then, assumption \([\text{A5}]\) is satisfied with \( \epsilon \equiv 0 \).

**Remark 3.14.** When \( A \) is finite, only assumption \([\text{A2}]\) has to be checked in the first part of Theorem 3.8, and the second part of Theorem 3.8 shows that semidifferentiable maps \( \mathbb{R}^n \to \mathbb{R} \) are stable by max, a well-known fact \([\text{RW98}]\) Exercise 10.27. More generally, the part of \([\text{RW98}]\) Theorem 10.31 which asserts that lower-\( C^1 \) maps are semidifferentiable may be recovered from Theorem 3.8 (in \([\text{RW98}]\), a map \( f : \mathbb{R}^n \to \mathbb{R} \) is said to be lower-\( C^1 \) if it can be written as (3.14) with \( A \) compact, \( x \mapsto f_a(x) \) of class \( C^1 \), and \((a, x) \mapsto (f_a(x), (f_a)'_v) \) continuous).

**Remark 3.15.** The following counterexample shows that the upper-semicontinuity assumptions are useful in Theorem 3.8. Take any function \( f : \mathbb{R} \to \mathbb{R} \) of Lipschitz constant 1, which is not semidifferentiable (for instance, \( f(x) = \frac{x}{2} \sin(\log |x|) \)), which is not semidifferentiable at 0). Then, \( f : [-1, 1] \to \mathbb{R} \) can be written as (3.14) with \( A = [-1, 1] \) and

\[
f_a(x) = f(a) - |x - a|.
\]

All the assumptions of Theorem 3.8 are satisfied, except the requirement in \([\text{A3}]\) and \([\text{A4}]\) that \( a \mapsto (f_a)'_v(x) \) and \( a \mapsto f_a(v) + t_0(f_a)'_v(x) \) be upper semicontinuous. Indeed,

\[
(f_a)'_v(x) = \begin{cases} -x & \text{if } v > a, \\ x & \text{if } v < a, \\ -|x| & \text{if } v = a, \end{cases}
\]

so that \((f_a)'_v(x) = -|x| < \limsup_{a \to x} (f_a)'_v(x) = +|x|\), unless \( x = 0 \).
4. Semidifferentials of order preserving and nonexpansive maps

In this section, we consider various classes of maps on cones, and establish auxiliary results concerning their semidifferentials.

Let \((X, \| \cdot \|)\) be a Banach space endowed with a partial ordering \(\leq\), and \(f\) be a map from a subset \(D \subset X\), to \(X\). Recall that \(f\) is order preserving if for all \(x, y \in D, x \leq y \implies f(x) \leq f(y)\). We shall say that \(f\) is convex if \(f((1-t)x+ty) \leq (1-t)f(x) + tf(y)\) for all \(0 \leq t \leq 1\) and \(x, y \in D\), such that \((1-t)x + ty \in D\). We shall say that \(f\) is subhomogeneous if \(tf(y) \leq f(ty)\) for all \(0 \leq t \leq 1\) and \(y \in D\), such that \(ty \in D\). Also, we shall say that \(f\) satisfies a property (for instance order preserving, or homogeneous,…) in a neighborhood of a point \(v\) of \(D\), if there exists a neighborhood \(V\) of \(v\) in \(D\) such that \(f\mid_V\) satisfies this property.

We shall systematically use the following well-known elementary properties (see for instance [Nus88, Tho63, Bus73, Pot77]):

**Lemma 4.1.** Let \(C\) be a proper cone, \(u \in C \setminus \{0\}\), \(\psi \in C^* \setminus \{0\}\) such that \(\psi(u) > 0\) and let \(\Sigma_u = \{x \in C_u \mid \psi(x) = \psi(u)\}\).

(i) If \(f : C_u \to C\) is order preserving and homogeneous, then \(f(C_u) \subset C_{f(u)}\) and \(f\) is nonexpansive with respect to \(d\) and \(\delta\).

(ii) If \(f : C_u \to C\) is order preserving and subhomogeneous, then \(f(C_u) \subset C_{f(u)}\) and \(f\) is nonexpansive with respect to \(d\), and the restriction \(f\mid_{\Sigma_u}\) of \(f\) to \(\Sigma_u\) is nonexpansive with respect to \(d\).

We now introduce additive analogues of (sub-) homogeneity: we shall say that a self map \(h\) of a Banach space \((X, \| \cdot \|)\) is additively homogeneous with respect to \(v \in X\) if, for all \(x \in X\) and \(t \in \mathbb{R}\), \(h(x + tv) = h(x) + tv\); similarly, we shall say that \(h\) is additively subhomogeneous with respect to \(v\) if, for all \(x \in X\) and \(t \geq 0\), \(h(x + tv) \leq h(x) + tv\). The following lemma relates the properties of \(f\) with those of \(f'\).

**Lemma 4.2.** Let \(C\) be a proper cone with nonempty interior in a Banach space \((X, \| \cdot \|)\). Let \(G\) be an open subset of \((X, \| \cdot \|)\) included in \(C\) and \(f : G \to \text{int } C\). Let \(v \in G\) be a fixed point of \(f\) : \(f(v) = v\). Let \(\psi \in C^* \setminus \{0\}\) be such that \(\psi(v) = 1\) and denote \(\Sigma = \{x \in \text{int } C \mid \psi(x) = 1\}\). Assume that \(f\) is semidifferentiable at \(v\).

The following implications hold:

(i) If \(f\) is order preserving in a neighborhood of \(v\), then \(f'_v : X \to X\) is order preserving.

(ii) If \(f\) is convex in a neighborhood of \(v\), then \(f'_v : X \to X\) is convex.

(iii) If \(f\) is homogeneous in a neighborhood of \(v\), then \(f'_v\) is additively homogeneous with respect to \(v\).

(iv) If \(f\) is subhomogeneous in a neighborhood of \(v\), then \(f'_v\) is additively subhomogeneous with respect to \(v\).

(v) Assume that there exists \(\delta > 0\) such that \(f(tv) \leq tf(v)\) for all \(1 \leq t \leq 1+\delta\). Then, \(f'_v(v) \leq v\).

(vi) Assume that there exists \(\delta > 0\) such that \(\delta \leq 1\) and \(tf(v) \leq f(tv)\) for all \(1 - \delta \leq t \leq 1\). Then, \(f'_v(-v) \geq -v\).

(vii) If \(f\) is nonexpansive with respect to \(d\) in a neighborhood of \(v\), then \(f'_v\) is nonexpansive with respect to \(\| \cdot \|\).

(viii) If \(f\mid_{G \cap \Sigma}\) is nonexpansive with respect to \(d\) in a neighborhood of \(v\), then \(f'_v\mid_{\text{int } G \cap \Sigma}\) is nonexpansive with respect to \(\omega_v\).
Proof. We shall only need the definition (3.2) of $f'_v$.

(i) If $f$ is order preserving in a neighborhood of $v$, then for all $x, y \in X$ such that $x \leq y$, we have $f(v + tx) \leq f(v + ty)$ for all $t > 0$ small enough. Hence, from (3.2), $f'_v(x) \leq f'_v(y)$, which shows that $f'_v$ is order preserving.

(ii) If $f$ is convex in a neighborhood of $v$, then for all $x, y \in X$ and $s \in [0, 1]$, we have $f(v + t((1-s)x + sy)) = f((1-s)(v + tx) + s(v + ty)) \leq (1-s)f(v + tx) + sf(v + ty)$ for all $t > 0$ small enough. Hence, from (3.2), $f'_v((1-s)x + sy) \leq (1-s)f'_v(x) + sf'_v(y)$, which shows that $f'_v$ is convex.

(iii) If $f$ is homogeneous in a neighborhood of $v$, then for all $x \in X$, $s \in \mathbb{R}$,

$$f(v + t(x + sv)) = f((1 + ts)(v + \frac{t}{1 + ts}x)) = (1 + ts)f(v + \frac{t}{1 + ts}x)$$

for all $t > 0$ small enough. Since $f(v) = v$, this leads to

$$(4.1) \quad \frac{f(v + t(x + sv)) - f(v)}{t} = \frac{1 + ts}{t} (f(v + \frac{t}{1 + ts}x) - f(v)) + sv$$

for all $t > 0$ small enough. Using (3.2) and (4.1), we get

$$f'_v(x + sv) = f'_v(x) + sv$$

which shows that $f'_v$ is additively homogeneous with respect to $v$.

(iv) If $f$ is subhomogeneous in a neighborhood of $v$, then $f(tx) \leq tf(x)$ for all $x \in X$ and $t \geq 1$ such that $x$ and $tx$ are sufficiently close to $v$. By the same arguments as for (iii) we obtain that for all $x \in X$, $s \geq 0$,

$$f(v + t(x + sv)) \leq (1 + ts)f(v + \frac{t}{1 + ts}x)$$

and

$$(4.2) \quad \frac{f(v + t(x + sv)) - f(v)}{t} \leq \frac{1 + ts}{t} (f(v + \frac{t}{1 + ts}x) - f(v)) + sv$$

for all $t > 0$ small enough. Using (3.2) and (4.2), we get

$$f'_v(x + sv) \leq f'_v(x) + sv$$

for all $s \geq 0$, which shows that $f'_v$ is additively subhomogeneous with respect to $v$.

(v) Assume that there exists $\delta > 0$ such that $f(tv) \leq tf(v)$ for all $1 \leq t \leq 1 + \delta$. Then, using $f(v) = v$, we get for all $0 < s \leq \delta$

$$\frac{f(sv) - f(v)}{s} \leq f(v) = v$$

and passing to the limit when $s$ goes to $0$, we obtain $f'_v(v) \leq v$.

(vi) Assume that there exists $\delta > 0$ such that $\delta \leq 1$ and $tf(v) \leq f(tv)$ for all $1 - \delta \leq t \leq 1$. Then, similarly to case (v), we get for all $0 < s \leq \delta$

$$\frac{f(v - sv) - f(v)}{s} \geq -f(v) = -v$$

and passing to the limit when $s$ goes to $0$, we obtain $f'_v(-v) \geq -v$.

(vii) If $f$ is nonexpansive with respect to $\tilde{d}$ in a neighborhood of $v$, then for all $x, y \in X$ such that $x \neq y$,

$$(4.3) \quad \frac{\tilde{d}(f(v + tx), f(v + ty))}{\tilde{d}(v + tx, v + ty)} \leq 1$$
for all $t > 0$ small enough. In particular $f(v + tx)$ and $f(v + ty)$ tend to $v$ in $(\text{int} C, d)$ when $t \to 0^+$. Using (2.23) and (4.3), we get
\begin{equation}
\lim_{t \to 0^+} \frac{\|f(v + tx) - f(v + ty)\|}{\|tx - ty\|} \leq 1 .
\end{equation}

Since for any proper cone $C$ and $v \in \text{int} C$ there exists a constant $\kappa$ such that $\|\cdot\|_v \leq \kappa \|\cdot\|$, the convergence in (3.2) holds not only for the topology of the norm $\|\cdot\|$ but also for the topology of $\|\cdot\|_v$. Gathering (4.4) with (3.2) for the topology of $\|\cdot\|_v$, we deduce
\begin{equation}
\frac{\|f'_v(x) - f'_v(y)\|}{\|x - y\|_v} \leq 1 ,
\end{equation}
which shows that $f'_v$ is nonexpansive with respect to $\|\cdot\|_v$.

(viii) If $f|_{G \cap \Sigma}$ is nonexpansive with respect to $d$ in a neighborhood of $v$, then, for all $x, y \in \psi^{-1}(0)$ such that $x \neq y$,
\begin{equation}
d(f(v + tx), f(v + ty)) \leq 1
\end{equation}
for all $t > 0$ small enough (since $v + tx$ and $v + ty \in G \cap \Sigma$ for all $t > 0$ small enough). Hence, using (2.24), we get
\begin{equation}
\lim_{t \to 0^+} \frac{\omega_v(f(v + tx) - f(v + ty))}{\omega_v(tx - ty)} \leq 1 .
\end{equation}
As was said before, the convergence in (3.2) holds for the topology of $\|\cdot\|_v$; hence by (2.8), we get that
\begin{equation}
\lim_{t \to 0^+} \omega_v \left( \frac{f(v + tz) - f(v)}{t} - f'_v(z) \right) = 0 ,
\end{equation}
for all $z \in \psi^{-1}(0)$. Using this convergence together with (4.5), we deduce
\begin{equation}
\frac{\omega_v(f'_v(x) - f'_v(y))}{\omega_v(x - y)} \leq 1 ,
\end{equation}
which shows that $f'_v|_{\psi^{-1}(0)}$ is nonexpansive with respect to $\omega_v$. \hfill \Box

We shall also need:

**Lemma 4.3.** Let $h$ denote a self-map of a Banach space $(X, \|\cdot\|)$ endowed with a partial ordering $\leq$, and let $v \in X$. If $h$ is convex, homogeneous, and if $h(v) \leq v$, then $h$ is additively subhomogeneous with respect to $v$.

**Proof.** If $h$ is convex and $h(v) \leq v$, then using the homogeneity of $h$, we get for all $t \geq 0$ and $x \in X$,
\begin{equation}
h(x + tv) \leq \frac{1}{2}(h(2x) + h(2tv)) = h(x) + th(v) \leq h(x) + tv ,
\end{equation}
which shows that $h$ is additively subhomogeneous with respect to $v$. \hfill \Box

Symmetrically, if $h : X \to X$ is concave, homogeneous and such that $h(-v) \geq -v$, then $h$ is additively subhomogeneous with respect to $v$. Lemma 4.3 covers only a special case: a homogeneous and additively subhomogeneous map need not be convex or concave (consider for instance $h : \mathbb{R}^2 \to \mathbb{R}^2, h(x_1, x_2) = ((x_1 \vee x_2) \wedge x_1/2, x_2)$, which is homogeneous and additively subhomogeneous with respect to $(1,1)$).
If $C,G,f$ are as in Lemma 4.2 to study the eigenvectors of $f$, we shall pick a linear form $\psi \in C^* \setminus \{0\}$, define the set $\Sigma = \{x \in \text{int} C \mid \psi(x) = 1\}$, and consider the map

\[
(4.6) \quad \tilde{f} : G \to \Sigma, \quad \tilde{f}(x) = \frac{f(x)}{\psi(f(x))}.
\]

The following lemma states some basic properties of $\tilde{f}$.

**Lemma 4.4.** Let $C$ be a proper cone with nonempty interior in a Banach space $(X, \|\cdot\|)$. Let $G$ be an open subset of $(X, \|\cdot\|)$ included in $C$ and let $f : G \to \text{int} C$. Let $\psi \in C^* \setminus \{0\}$, $\Sigma = \{x \in \text{int} C \mid \psi(x) = 1\}$, let $\tilde{f}$ be defined by (4.6) and let $g = \tilde{f}_{|G \cap \Sigma}$. If $f_{|G \cap \Sigma}$ is nonexpansive with respect to $d$, so is $g$. Let $v \in G \cap \Sigma$ be a fixed point of $f : f(v) = v$. Assume that $f$ is semidifferentiable at $v$. Then, $\tilde{f}$ is semidifferentiable at $v$, and

\[
(4.7) \quad \tilde{f}_v(x) = f'_v(x) - \psi(f'_v(x))v \quad \forall x \in X.
\]

Moreover, if $f_{|G \cap \Sigma}$ is nonexpansive with respect to $d$ in a neighborhood of $v$, then $g'_v = f'_{|G \cap \Sigma}|_{\omega_v}$ is nonexpansive with respect to $\omega_v$.

**Proof.** By the definition of $d$, we have $d(\lambda x, \mu y) = d(x, y)$ for all $\lambda, \mu > 0$ and $x, y \in \text{int} C$. Hence, if $f_{|G \cap \Sigma}$ is nonexpansive with respect to $d$, then for all $x, y \in G \cap \Sigma$,

\[
d(g(x), g(y)) = d\left(\frac{f(x)}{\psi(f(x))}, \frac{f(y)}{\psi(f(y))}\right) = d(f(x), f(y)) \leq d(x, y),
\]

which shows that $g$ is nonexpansive with respect to $d$.

Consider the map $R : \text{int} C \to \Sigma, y \mapsto \frac{y}{\psi(y)}$. We have $\tilde{f} = R \circ f$. Since $\psi$ is linear, thus differentiable at any point $w \in X$, and $\psi(y) > 0$ for all $y \in \text{int} C$, it follows that $R$ is differentiable at any $w \in \text{int} C$, with

\[
(4.8) \quad R'_w(y) = \frac{y}{\psi(w)} - \frac{\psi(y)w}{\psi(w)^2}.
\]

In particular $R$ is differentiable at $v \in \text{int} C$, thus $R$ is semidifferentiable at $f(v) = v$ and $R'_{f(v)}$ is uniformly continuous on all bounded sets. Moreover $\tilde{f}$ is semidifferentiable at $v$. Hence applying Lemma 3.3 we get that $\tilde{f}$ is semidifferentiable at $v$ and that $\tilde{f}'_v = R'_v \circ f'_v$. From (4.8) and $\psi(v) = 1$, we get (4.7).

If $f_{|G \cap \Sigma}$ is nonexpansive with respect to $d$ in a neighborhood of $v$, then by the same arguments as above, $g = \tilde{f}_{|G \cap \Sigma}$ is nonexpansive with respect to $d$ in a neighborhood of $v$, and by Lemma 4.2 (viii) applied to $\tilde{f}$, $g'_v = f'_{|G \cap \Sigma}|_{\omega_v}$ is nonexpansive with respect to $\omega_v$. $\square$

The following result, which controls $x - h(x)$ in terms of the fixed point set of an order preserving additively subhomogeneous map $h$, will play a key role in the proof of the uniqueness theorem for eigenvectors (Theorem 7.5 below).

**Lemma 4.5.** Let $C$ be a proper cone with nonempty interior in a Banach space $(X, \|\cdot\|)$ and let $v \in \text{int} C$. Let $h : X \to X$ be order preserving and additively subhomogeneous with respect to $v$. Assume that the set $S = \{y \in X \mid h(y) = y\}$ of
fixed points of $h$ is nonempty. We have, for all $x \in X$,
\begin{align}
(4.9) & \quad m(x-h(x)/v) \leq \inf_{y \in S} m(x-y/v) \lor 0, \\
(4.10) & \quad M(x-h(x)/v) \geq \sup_{y \in S} M(x-y/v) \land 0.
\end{align}

Proof. We first show that if $h(0) = 0$, then
\begin{equation}
(4.11) \quad M(x-h(x)/v) \geq M(x/v) \land 0 \quad \forall x \in X.
\end{equation}

Let $x \in X$ and denote $\beta = M(x/v)$ and $z = x - h(x)$. Then, $x \leq \beta v \leq (\beta \lor 0)v$. Since $h(0) = 0$ and $h$ is order preserving and additively subhomogeneous with respect to $v$, we get $h(x) \leq h((\beta \lor 0)v) \leq h(0) + (\beta \lor 0)v = (\beta \lor 0)v$. Hence,
\begin{equation}
(4.12) \quad x = z + h(x) \leq M(z/v)v + (\beta \lor 0)v = (M(x/v) + \beta \lor 0)v.
\end{equation}

Since $\beta = \inf\{a \in \mathbb{R} \mid x \leq av\}$, we deduce from (4.12) that $\beta \leq M(z/v) + \beta \lor 0$; thus $\beta \land 0 = \beta - \beta \lor 0 = M(z/v)$, which shows (4.11).

Applying (4.11) to $-x$ and replacing $h$ by $h^{-}(x) = -h(-x)$, which is order preserving, additively subhomogeneous with respect to $v$ and satisfies $h^{-}(0) = 0$, we get $M(-x + h(x)/v) \geq M(-x/v) \land 0$. Since $m(x/v) = -M(-x/v)$, this shows that
\begin{equation}
(4.13) \quad m(x-h(x)/v) \leq m(x/v) \lor 0 \quad \forall x \in X.
\end{equation}

Let $y \in S$ and consider $h_y : X \to X$, $x \mapsto h_y(x) = h(y + x) - y$. Then, $h_y(0) = 0$ and $h_y$ is order preserving and additively subhomogeneous with respect to $v$: $h_y(x + tv) = h(y + x + tv) - y \leq h(y + x) + tv - y = h_y(x) + tv$ for all $t \geq 0$. Replacing $h$ by $h_y$ in (4.11), we get
\[ M(x + y - h(x+y)/v) \geq M(x/v) \land 0 \quad \forall x \in X; \]
then, replacing $x$ by $x - y$, we obtain
\[ M(x - h(x)/v) \geq M(x - y/v) \land 0 \quad \forall x \in X. \]
Taking the supremum with respect to $y \in S$ leads to (4.10). Similarly, applying (4.13) to $h_y$ and replacing $x$ by $x - y$, we obtain (4.9). 

Let $(X, \| \cdot \|)$ be an AM-space with unit, denoted by $e$, and let $f : X \to X$ be a map. We shall say that $f$ is additively homogeneous (resp. additively subhomogeneous) if $f$ is additively homogeneous (resp. subhomogeneous) with respect to $e$, that is (see above), $f(x + te) = f(x) + te$ (resp. $f(x + te) \leq f(x) + te$), for all $x \in X$ and $t \in \mathbb{R}$ (resp. $t \geq 0$). We call an additive eigenvector of $f$ a vector $x \in X$ such that $f(x) = x + \lambda e$, for some $\lambda \in \mathbb{R}$. We denote by $\omega$ the seminorm $\omega_e$ defined in (2.7).

Additive versions of some results of Lemmas 4.1 and 4.2 are easy to check and are given without proof (a variant of Lemma 4.6 can be found in [CT80]).

**Lemma 4.6** (Compare with [CT80]). Let $(X, \| \cdot \|)$ be an AM-space with unit, denoted by $e$, and $\omega$ denotes the seminorm $\omega_e$ defined in (2.7). Let $\psi \in (X^+)^* \setminus \{0\}$.

(i) If $F : X \to X$ is order preserving and additively homogeneous, then $F$ is nonexpansive with respect to $\| \cdot \|$ and $\omega$.

(ii) If $F : X \to X$ is order preserving and additively subhomogeneous, then $F$ is nonexpansive with respect to $\| \cdot \|$, and the restriction $F|_{\psi^{-1}(0)}$ of $F$ to $\psi^{-1}(0)$ is nonexpansive with respect to $\omega$.
Lemma 4.7. Let \((X, \| \cdot \|)\) be an AM-space with unit. Let \(G\) be an open subset of \(X\) and let \(F : G \to X\). Let \(v \in G\) be a fixed point of \(F\): \(F(v) = v\). Assume that \(F\) is semidifferentiable at \(v\). The following implications hold:

(i) If \(F\) is order preserving in a neighborhood of \(v\), then \(F' : X \to X\) is order preserving.

(ii) If \(F\) is convex in a neighborhood of \(v\), then \(F' : X \to X\) is convex.

(iii) If \(F\) is additively homogeneous in a neighborhood of \(v\), then \(F'\) is additively homogeneous.

(iv) If \(F\) is additively subhomogeneous in a neighborhood of \(v\), then \(F'\) is additively subhomogeneous.

(v) If \(F\) is nonexpansive with respect to \(\| \cdot \|\) in a neighborhood of \(v\), then \(F'\) is nonexpansive with respect to \(\| \cdot \|\).

5. Spectral radius notions and nonlinear Fredholm property

Some of our main results rely on some mild compactness (nonlinear Fredholm type) conditions. In order to discuss it, we first recall the definition of several notions of nonlinear spectral radius, as well as some results of [MPN02,AGN11], on generalized measures of noncompactness.

5.1. Spectral radius, measures of noncompactness, and essential spectral radius. Let \(C\) be a cone of a Banach space \((X, \| \cdot \|)\) and \(h\) be a map, homogeneous (of degree 1) and continuous, from \(C\) to \(C\). Following [MPN02], we define:

\[
\tilde{r}_C(h) = \lim_{k \to \infty} \frac{\|h^k\|_C^{1/k}}{\inf_{k \geq 1} \frac{\|h^k\|_C^{1/k}}{k}},
\]

where \(\|h^k\|_C\) is defined in (3.7).

When \(C\) is obvious and in particular when \(C = X\), \(C\) will be omitted in the previous notation. Since \(h\) is continuous at 0, we have \(0 \leq \tilde{r}_C(h) < +\infty\). The equality of the limit and the infimum in (5.1) follows from \(\|h^{k+\ell}\| \leq \|h^k\| \|h^\ell\|\). The number \(\tilde{r}_C(h)\) is called Bonsall’s cone spectral radius of \(h\). If now \(C\) has nonempty interior \(\text{int} \, C\), we define another spectral radius:

\[
cw_C(h) = \inf \{ \lambda > 0 \mid \exists x \in \text{int} \, C, \ h(x) \leq \lambda x \}.
\]

In [MPN02] and then in [AGN11] these spectral radii are compared with other notions of spectral radius like the cone spectral radius and the cone eigenvalue spectral radius. We recall below some of the results of [AGN11] that are needed in the following sections.

Lemma 5.1 ([AGN11] Lemma 7.3). Let \(C\) be a proper cone of a Banach space \((X, \| \cdot \|)\), with nonempty interior, and let \(h : C \to C\) be a continuous, homogeneous and order preserving map. Then,

\[
\tilde{r}_C(h) \leq cw_C(h).
\]

A map \(\nu\) from the set of bounded subsets of \(X\) to the set of real nonnegative numbers is called a homogeneous generalized measure of noncompactness if for all
bounded subsets $A, B$ of $X$ and for all real scalars $\lambda$,

$$
(5.3a) \quad \nu(A) = 0 \iff \text{clo } A \text{ is compact },
$$

$$
(5.3b) \quad \nu(A + B) \leq \nu(A) + \nu(B),
$$

$$
(5.3c) \quad \nu(\text{clo } \text{conv}(A)) = \nu(A),
$$

$$
(5.3d) \quad \nu(\lambda A) = |\lambda| \nu(A),
$$

$$
(5.3e) \quad A \subset B \implies \nu(A) \leq \nu(B).
$$

We use the notation $\text{clo } A$ for the closure of a set $A$ and $\text{conv } A$ for its convex hull. Note that equations 5.3 imply that $\nu(A \cup K) = \nu(A)$ whenever $A$ is a bounded subset of $X$ and $K$ is a compact subset of $X$; see e.g. Prop. 2.2 of [MPN11a]. They also imply that $\nu(A + K) = \nu(A)$, in particular

$$
(5.4) \quad \nu(A + x) = \nu(A) \quad \text{for all } x \in X.
$$

For every bounded subset $A$ of $X$, let $\alpha(A)$ denote the infimum of all $\delta > 0$ such that there exists an integer $k$ and $k$ subsets $S_1, \ldots, S_k \subset A$ of diameter at most $\delta$, such that $A = S_1 \cup \cdots \cup S_k$. The map $\alpha$, introduced by Kuratowski and further studied by Darbo (see [MPN02] for references), is a particular case of a homogeneous generalized measure of noncompactness.

If $h : D \subset X \to X$ is a map sending bounded sets to bounded sets, $\nu$ is a homogeneous generalized measure of noncompactness, and $D \subset D$, we define

$$
\nu_D(h) = \inf \{ \lambda > 0 \mid \nu(h(A)) \leq \lambda \nu(A), \text{ for all bounded sets } A \subset D \}.
$$

If in addition $h(D) \subset D$, we define

$$
\rho_D(h) = \lim_{k \to \infty} (\nu_D(h^k))^{1/k} = \inf_{k \geq 1} \nu_D(h^k)^{1/k}.
$$

If $C$ is a cone, $h : C \to C$ is homogeneous and Lipschitz continuous with constant $\kappa$, and $\alpha$ is the Kuratowski-Darbo generalized measure of noncompactness described above, then $\alpha_C(h) \leq \kappa$. A general map $h : D \subset X \to X$, such that $\nu_D(h) \leq k < 1$, is called a $k$-set contraction (with respect to $\nu$). If $C$ is a cone and $h : C \to C$ is homogeneous, $\rho_C(h)$ is called the cone essential spectral radius of $h$ associated to the homogeneous generalized measure of noncompactness $\nu$. (We note that a more refined notion of cone essential spectral radius, which avoids various pathologies which can occur with the above definition, has been recently developed in [MPN10]. See also [MPN11b].)

We saw in Lemma 4.2 that several elementary properties (including monotonicity) of a map carry over to its semidifferential. The same turns out to be true for properties involving $k$-set contractions.

**Proposition 5.2.** Let $f : G \to X$ be a map, and let $v \in G$ be a fixed point of $f : f(v) = v$. Assume that $f$ is semidifferentiable at $v$ with respect to a closed cone $C$. Then, for any relative neighborhood $U$ of $v$ in $v + C$ such that $U \subset G$ and for any generalized measure of noncompactness $\nu$ on $X$, we have

$$
(5.5a) \quad \nu_C(f'_v) \leq \nu_U(f).
$$

Moreover, if there exists a neighborhood $U$ of $v$ in $v + C$, such that $U \subset G$ and $f(U) \subset U$, then $f'_v$ sends $C$ to itself, and if in addition $f'_v$ is uniformly continuous on bounded sets of $C$, we have

$$
(5.5b) \quad \rho_C(f'_v) \leq \rho_U(f).
$$
Proof. Let us prove (5.5a). Let \( S \) be a bounded subset of \( C \). Since \( f \) is semidifferentiable at \( v \) with respect to \( C \), there exists a neighborhood \( U \) of \( v \) in \( v + C \), such that \( U \subset G \) and for any such a neighborhood \( U \), there exists \( t_0 > 0 \) such that \( v + tS \subset U \) for \( 0 \leq t \leq t_0 \), since \( S \) is bounded in \( C \). Moreover, from Lemma 3.4 it follows that

\[
\epsilon(t) := \sup_{x \in S} t^{-1} \| f(v + tx) - f(v) - tf'_v(x) \| \to 0 \text{ when } t \to 0^+ .
\]

Then for all \( t > 0 \) such that \( t \leq t_0 \), we have

\[
tf'_v(x) - f(v + tx) + f(v) \in B(0, te(t)), \text{ for all } x \in S ,
\]

which implies that

\[
tf'_v(S) \subset f(v + tS) - f(v) + B(0, te(t)) .
\]

Applying \( \nu \), and using properties (5.3d), (5.3e), (5.4), (5.3b), we get

\[
\nu(tf'_v(S)) = \nu(tf'_v(S)) \\
\leq \nu(f(v + tS) - f(v) + B(0, te(t))) \\
\leq \nu(f(v + tS)) + \nu(B(0, te(t))) \\
\leq \nu(f(v + tS)) + t\epsilon(0)(B(0, 1)) .
\]

Since \( v + tS \subset U \) for \( t \leq t_0 \), we obtain, by definition of \( \nu_U(f) \),

\[
\nu(f(v + tS)) \leq \nu_U(f)\nu(v + tS) .
\]

By (5.4) and (5.3d), \( \nu(v + tS) = \nu(tS) = t\nu(S) \). We now get from (5.6)

\[
\nu(tf'_v(S)) \leq \nu_U(f)(S) + \epsilon(t)\nu(B(0, 1))
\]

for all \( t \) small enough; hence \( \nu(tf'_v(S)) \leq \nu_U(f)\nu(S) \), which shows (5.5a).

Assume now that there exists a neighborhood \( U \) of \( v \) in \( v + C \), such that \( U \subset G \) and \( f(U) \subset U \). Then, \( f(U) \subset U \subset v + C \), and since \( C \) is closed, we deduce that \( f'_v(C) \subset C \). Assume in addition that \( f'_v \) is uniformly continuous on bounded sets of \( C \) and let us prove (5.5b). Since \( f'_v \) is uniformly continuous on bounded sets of \( C \), so is \( (f'_v)^n \), since, by (3.3), \( f'_v \) sends bounded sets to bounded sets. Using the chain rule (Lemma 3.4), we obtain by induction that \( f^n \) is semidifferentiable at \( v \) with respect to \( C \), and that \( (f^n)'_v = (f'_v)^n \). Then, applying (5.5a) to \( f^n \), we get \( \nu_C((f'_v)^n) \leq \nu_U(f^n) \). Taking the \( 1/n \) power and then the infimum over all \( n > 1 \), we get \( \rho_C(f'_v) \leq \rho_U(f) \).

5.2. A nonlinear Fredholm-type property. We now introduce a nonlinear Fredholm-type property, also considered in [AGN11], which will be required to establish the uniqueness result for fixed points and eigenvectors in Sections 6.1.7. If \( (X, \| \cdot \|) \) and \( (Y, \| \cdot \|) \) are Banach spaces, \( D \) is a subset of \( X \), and \( g : D \to Y \) is a map, we shall say that \( g \) has Property (F) when

(F) any sequence \( \{x_j \in D \mid j \geq 1\} \), bounded in \( X \), and such that \( g(x_j) \to_{j \to \infty} 0 \), has a convergent subsequence in \( X \).

In the point set topology literature, Property (F) corresponds to the property that the restriction of \( g \) to any closed bounded set of \( X \) is proper at 0. If \( X \) is finite dimensional, any map \( g : X \to Y \) has Property (F). When \( g \) is linear, \( g \) has Property (F) if, and only if, \( g \) is a semi-Fredholm linear operator with index in \( \mathbb{Z} \cup \{-\infty\} \), which means that \( g \) has a finite dimensional kernel and a closed range;
Lemma 5.3 ([AGN11] Lemma 4.1). If $D$ is a subset of a Banach space $(X, \| \cdot \|)$, and if $h : D \to X$ is a map sending bounded sets to bounded sets and such that $\nu_D(h) < 1$, then $\text{Id} - h$ has Property (F).

In the particular case where the homogeneous generalized measure of noncompactness $\nu$ is equal to the Kuratowski-Darbo generalized measure of noncompactness $\alpha$, and where $h$ is continuous, Lemma 5.3 is a consequence of Corollary 2 in Section E of [Nus71], which says more generally that the restriction of $\text{Id} - h$ to any closed bounded set of $X$ is proper (at any point).

Proposition 5.4 ([AGN11] Proposition 4.2). If $C$ is a cone of a Banach space $(X, \| \cdot \|)$, if $h : C \to C$ is homogeneous and uniformly continuous on bounded sets of $C$, and if either $\rho_C(h) < 1$ or $\tilde{r}_C(h) < 1$, then $\text{Id} - h$ has Property (F) on $C$. Moreover, when $\tilde{r}_C(h) < 1$, $0$ is the unique fixed point of $h$ in $C$.

6. General uniqueness and convergence results

In this section, we establish the main results of this paper, which concern the uniqueness of the fixed point of a semidifferentiable map and the convergence of the orbits to it. The results are already useful in the finite dimensional case, hence, the reader might wish at the first reading to ignore the technical compactness assumptions regarding Property (F), which are trivially satisfied in finite dimension.

6.1. Uniqueness of the fixed point. We study the uniqueness of the fixed point $v$ of a nonexpansive map defined on a metric space $(V, d)$. We shall need the following assumptions:

(B1) There exists a Banach space $(E, \| \cdot \|)$ such that $V$ is an open subset of $E$ and that for any $U$ contained in $V$, $U$ is open in the $d$-metric topology iff it is open in the norm topology of $E$. In addition, we require that

$$d(x, y) \sim \| x - y \| \text{ when } x, y \to v \text{ in } V,$$

where by (6.1), we mean that for all $\lambda > 1$, there exists a neighborhood $U$ of $v$ in $(V, d)$ such that

$$\frac{1}{\lambda} \| x - y \| \leq d(x, y) \leq \lambda \| x - y \| \quad \forall x, y \in U.$$

(B2) The balls of $(V, d)$ are convex in $E$.

(B3) For all $w \in V$, and $s \in (0, 1)$,

$$\Gamma_s := \{ z \in V \mid d(z, v) = sd(v, w), \ d(z, w) = (1 - s)d(v, w) \} \neq \emptyset.$$ 

To interpret assumption [(B3)], let us recall that a metric space $(V, d)$ is strongly metrically convex or is a geodesic space if for all $x, y \in V$, there exists a (minimal) geodesic from $x$ to $y$, that is, a continuous path, $z : [0, 1] \to V$ such that $z(0) = x$, $z(1) = y$, and $d(z(s), z(t)) = |s - t|d(x, y)$ for all $s, t \in [0, 1]$. Assumption [(B3)] holds when $(V, d)$ is strongly metrically convex. Conversely, if $(V, d)$ is a complete metric space and if assumption [(B3)] holds for all $v \in V$, or more generally, if $V$ is metrically convex, which means that for all $x, y \in V$, there exists $w \in V$ such that $x \neq w, y \neq w$ and $d(x, y) = d(x, w) + d(w, y)$, then a theorem of K. Menger (see [Blu53] Th. 14.1, page 41]) asserts that $(V, d)$ is strongly metrically convex.
Assumptions [(B1)] [(B2)] and [(B3)] are trivially satisfied when \( V = X \) and \( d(x, y) = ||x - y|| \) for some Banach space \( (X, ||\cdot||) \).

Almost all the uniqueness results of this paper will be applications of the following general theorem.

**Theorem 6.1.** Let \((V,d)\) be a complete metric space satisfying [(B1)] [(B3)]. \(G\) be an open subset of \(V\), \(f : G \to V\) be a nonexpansive map and \(v \in G\) be a fixed point of \(f\) : \(f(v) = v\). Make the following assumptions:

(A1) \(f : G \to E\) is semidifferentiable at \(v\).

(A2) The map \(Id - f'_v : E \to E\) has Property (F).

(A3) The fixed point \(f'_v : E \to E\) is unique: \(f'_v(x) = x, x \in E \Rightarrow x = 0\).

Then, the fixed point of \(f\) in \(G\) is unique: \(f(w) = w, w \in G \Rightarrow w = v\).

Theorem 6.1 can be remembered by saying that the uniqueness of the fixed point of \(f'_v\) implies the uniqueness of the fixed point of \(f\), under assumptions which, as we will see in Sections 7 and 9, are fulfilled in many situations relative to cones.

In many applications, the map \( f'_v \) is much "simpler" than \( f \), and the uniqueness of the fixed point, [(A3)] can be proved by direct algebraic or combinatorial means.

An example of such a situation will be given in Section 11.

**Remark 6.2.** Assumption [(B1)] implies that there exists \( \varepsilon > 0 \), such that \( U = B(v, \varepsilon) \) satisfies (5.2), where in any metric space \((X, d)\), we denote by \( B(x, \rho) := \{y \in X \mid d(y, x) \leq \rho\}\) the closed ball of \( X \) with center \( x \in X \) and radius \( \rho \geq 0 \). Thus, \( B(v, \varepsilon) \) is a neighborhood of \( v \) in \((E, ||\cdot||)\), and the completeness of \( B(v, \varepsilon) \) for \( d \) is equivalent to its completeness for \(||\cdot||\). But for a normed vector space, the completeness of any closed subset with nonempty interior is equivalent to the completeness of the space. Therefore, the completeness of \( B(v, \varepsilon) \) for \( d \) is equivalent to the completeness of \((E, ||\cdot||)\), and in the assumptions of Theorem 6.1, one may either omit the completeness of \((V, d)\) or that of \((E, ||\cdot||)\).

**Remark 6.3.** In Theorem 6.1, assumption [(A2)] may be restrictive. Consider \( X = C_c([0,1]) \) the Banach space of continuous functions from \([0,1]\) to \( \mathbb{R} \), endowed with the sup-norm \(||\cdot||_\infty\), and let \( e \) denote the function identically 1 on \( X \). Then \( X \) is an AM-space with unit \( e \) and pointwise order \( \leq \) (see Section 2.3). Let \( F : X \to X \) be defined by \( F(x)(t) = x(\frac{1}{2}) \lor (x(t) - 1) \). One checks that \( F \) is additively homogenous \((F(x + \alpha e) = F(x) + \alpha e \forall \alpha \in \mathbb{R})\), and order preserving \((F(x) \leq F(y) \forall x \leq y)\). Then, from Lemma 4.6, \( F \) is nonexpansive with respect to the sup-norm.

Now let \( Y = C_c_0([0,1]) \subset X \) be the Banach subspace of maps \( x \in X \) such that \( x(0) = 0 \). The restriction \( f : Y \to Y \) of \( F \) to \( Y \) is also nonexpansive with respect to the sup-norm. Moreover, \( v \equiv 0 \) is the unique fixed point of \( f \), \( f \) is differentiable at \( v \) with semidifferential \( f'_v(x)(t) = x(\frac{1}{2}) \), and \( f'_v \) has no unique fixed point, whereas \( Id - f'_v \) does not have Property (F). Indeed, \( x_n(t) = t^n \) is such that \( x_n - f'_v(x_n) \) tends to 0 when \( n \) goes to infinity, whereas \( \langle x_n \mid n \geq 1 \rangle \) has no convergent subsequence (see [Bon58]).

As a corollary of Lemma 3.3, we obtain the following proposition, which gives in particular a sufficient condition for assumption [(A1)] of Theorem 6.1 to hold.

**Proposition 6.4.** Let \((V,d)\) be a metric space satisfying assumption [(B1)], let \( G \) be an open subset of \( V \), let \( v \in V \), and let \( f : G \to V \) be a nonexpansive map that has directional derivatives at \( v \) with respect to all \( x \in E \). Then, \( E \to E, x \mapsto f'_v(x) \) is nonexpansive, and if \( E \) is finite dimensional, \( f \) is semidifferentiable at \( v \).
Proof. We first prove that the map \( x \mapsto f'_v(x) \) (defined by (3.2)) is nonexpansive with respect to \( \| \cdot \| \). By taking \( X = C = E \) and a neighborhood \( U \) of \( v \) together with \( \lambda > 1 \) as in (3.2), so that \( f \) is Lipschitz of constant \( M = \lambda^2 \) in \( U \), we get from Lemma 3.2 that \( x \mapsto f'_v(x) \) is \( \lambda^2 \)-Lipschitz \( (E, \| \cdot \|) \rightarrow (E, \| \cdot \|) \). Since this holds for all \( \lambda > 1 \), \( x \mapsto f'_v(x) \) is nonexpansive \( (E, \| \cdot \|) \rightarrow (E, \| \cdot \|) \). The remaining part of the proposition follows from Lemma 3.2.

The proof of Theorem 6.1 relies on the following general local uniqueness result, which does not require \( f \) to be nonexpansive.

Lemma 6.5. Let \( (X, \| \cdot \|) \) be a normed vector space, \( f \) be a map from a subset \( G \subset X \) to \( X \), and \( v \) be a fixed point of \( f \) belonging to the interior of \( G \). Make the following assumptions:

(A1) \( f : G \rightarrow X \) is semidifferentiable at \( v \).
(A2) The map \( \text{Id} - f'_v : X \rightarrow X \) has Property (F).
(A3) The fixed point of \( f'_v : X \rightarrow X \) is unique: \( f'_v(x) = x \), \( x \in X \Rightarrow x = 0 \).

Then, there does not exist a sequence \( \{ v_n \} \) such that

\[
\lim_{n \to \infty} \| v_n - v \| = 0, \quad \text{and} \quad \lim_{n \to \infty} \| f(v_n) - v_n \| = 0.
\]

In particular \( v \) is isolated in the set of fixed points of \( f \).

Proof. Let \( \{ v_n \} \) be as in (6.4). Writing \( v_n := v + \epsilon_n x_n \) with \( \epsilon_n = \| v_n - v \| \), we get \( \lim_{n \to \infty} \epsilon_n = 0 \) and \( \| x_n \| = 1 \). Since the sequence \( \{ x_n \} \) is bounded, it follows from (3.3a) and (3.3b), which are satisfied thanks to (A1) that

\[
\lim_{n \to \infty} \left\| \frac{f(v_n) - f(v)}{\epsilon_n} - f'_v(x_n) \right\| = 0.
\]

Recalling that \( f(v) = v \) and using the second equation in (6.4) together with (6.5), we get

\[
\lim_{n \to \infty} \| x_n - f'_v(x_n) \| = 0.
\]

Since the sequence \( \{ x_n \} \) is bounded, assumption (A2) implies that \( x_n \) has a subsequence converging to a point \( x \in X \). Using the continuity of the semidifferential \( f'_v \), we obtain, from (6.6), \( x - f'_v(x) = 0 \). By assumption (A3), this implies that \( x = 0 \), a contradiction with \( \| x \| = 1 \). □

Remark 6.6. Let us give an example where all the assumptions of Lemma 6.5 are fulfilled except assumption (A2) and where the fixed point \( v \) is not isolated.

Consider \( X = C_b([0,1]) \) the Banach space of continuous functions \( x \) on \([0,1]\) to \( \mathbb{R} \) such that \( x(0) = 0 \), endowed with the sup-norm, and \( f : X \rightarrow X \) defined by \( f(x)(t) = x(\frac{1}{2}) + x(1)x(t) \). Note that \( f \) is not nonexpansive on \( X \). For all \( \gamma \in [0,1], \) let \( x_\gamma \in X \) be such that \( x_\gamma(t) = (1 - (\frac{1}{2})^\gamma)t^\gamma \) for all \( t \in [0,1] \). Then, \( x_\gamma \) is a fixed point of \( f \) for all \( \gamma \in [0,1] \), \( v := x_0 \equiv 0 \) and \( x_\gamma \) tends to \( v \) when \( \gamma \) tends to 0.

Hence, \( v \) is a nonisolated fixed point of \( f \). The map \( f \) is differentiable at \( v \) with semidifferential \( f'_v(x)(t) = x(\frac{1}{2}) \), and we already pointed out above that \( f'_v \) has 0 as a unique fixed point, whereas \( \text{Id} - f'_v \) does not have Property (F).

Proof of Theorem 6.1. Suppose, by way of contradiction, that there exists \( w \in G \) such that \( f(w) = w \), \( w \neq v \). Let \( R = d(v, w) > 0 \), and for all \( s \in (0,1) \), consider the set \( \Gamma_s \) defined by (6.8). Since \( G \) is open, \( v \in G \) and \( \Gamma_s \subset B(v, Rs) \), there exists
\( \bar{s} \in (0,1) \) such that \( \Gamma_s \subset G \), for all \( s \leq \bar{s} \). By assumption \([B3]\) for all \( s \in (0,1) \), there exists \( z_s \in \Gamma_s \).

Also, we have:

\[
\Gamma_s = \{ z \in V \mid d(z,v) \leq sd(v,w), \ d(z,w) \leq (1-s)d(v,w) \} \ .
\]

Indeed, if \( z \in V \) is such that \( d(z,v) \leq sd(v,w) \) and \( d(z,w) \leq (1-s)d(v,w) \), we get

\[
d(v,w) \leq d(z,v) + d(z,w) \leq sd(v,w) + (1-s)d(v,w) = d(v,w) ;
\]

hence \( d(z,v) = sd(v,w) \) and \( d(z,w) = (1-s)d(v,w) \). From \((6.7)\) and assumption \([B2]\) we deduce that \( \Gamma_s \) is convex. Because \( f \) is nonexpansive with respect to \( d \), \( f(v) = v \), \( f(w) = w \), and \( \Gamma_s \) is given by \((6.7)\), we have that \( f(\Gamma_s) \subset \Gamma_s \) (for \( s \leq \bar{s} \)). This property, together with the convexity of \( \Gamma_s \), allows us to consider, for \( t \in [0,1] \) and \( s \in [0,\bar{s}] \), the map \( f_{s,t} : \Gamma_s \to \Gamma_s \):

\[
f_{s,t}(x) = (1-t)f(x) + tz_s .
\]

By assumption \([B1]\) for all \( \lambda > 1 \), there exists \( 0 < s_{\lambda} \leq \bar{s} \) such that:

\[
\frac{1}{\lambda} \| x - y \| \leq d(x,y) \leq \lambda \| x - y \| \quad \forall x,y \in B(v,sR), \ 0 < s \leq s_{\lambda} .
\]

Since \( \Gamma_s \subset B(v,sR) \), and \( f \) is nonexpansive with respect to \( d \), we get (using \((6.9)\)) that for all \( x,y \in \Gamma_s \) and \( 0 < s \leq s_{\lambda} \),

\[
d(f_{s,t}(x), f_{s,t}(y)) \leq \lambda \| f_{s,t}(x) - f_{s,t}(y) \| \\
= \lambda (1-t) \| f(x) - f(y) \| \\
\leq \lambda^2 (1-t) d(f(x), f(y)) \\
\leq \lambda^2 (1-t) d(x,y) .
\]

Considering

\[
t_\lambda = \min(2(1 - \frac{1}{\lambda^2}), 1) \in (0,1] ,
\]

we get that

\[
c_\lambda := \lambda^2 (1 - t_\lambda) < 1 \quad \text{and} \quad \lim_{\lambda \to 1^+} t_\lambda = 0 .
\]

Hence, for all \( 0 < s \leq s_{\lambda} \) and \( t_\lambda \leq t \leq 1 \), \( f_{s,t} \) is a contraction mapping in \((\Gamma_s,d)\), with contraction factor \( c_\lambda \). Since \( \Gamma_s \) is closed in \( V \), \( (\Gamma_s,d) \) is a complete metric space, hence the contraction mapping principle implies that \( f_{s,t} \) has a unique fixed point \( v_{s,t} \in \Gamma_s \). By definition, \( v_{s,t} \) satisfies

\[
f(v_{s,t}) - v_{s,t} = t(f(v_{s,t}) - z_s) ,
\]

which leads to

\[
\| f(v_{s,t}) - v_{s,t} \| = t \| f(v_{s,t}) - z_s \| \\
\leq t \lambda d(f(v_{s,t}), z_s) \\
\leq t \lambda d(f(v_{s,t}), v) + d(v, z_s)) \\
\leq 2t \lambda Rs ,
\]

since \( f(v_{s,t}) \) and \( z_s \in \Gamma_s \).

Since \( v_{s,t} \in \Gamma_s \) and \( \Gamma_s \) is given by \((6.3)\), we get, using \((6.9)\),

\[
\frac{R_s}{\lambda} = \frac{d(v,v_{s,t})}{\lambda} \leq \| v_{s,t} - v \| \leq \lambda d(v,v_{s,t}) = \lambda Rs .
\]
The first inequality in (6.13) together with (6.12) yield
\[
\|f(v_{n,t}) - v_{n,t}\| \leq 2t\lambda^2.
\]
Let us choose a sequence \(\langle \lambda_n > 1 \mid n \geq 1 \rangle\), such that \(\lambda_n \to n \to \infty 1\), together with a sequence \(\langle s_n > 0 \mid n \geq 1 \rangle\), such that \(s_n \leq s_{\lambda_n}\) and \(s_n \to 0\). We set \(t_n := t_{\lambda_n}\) and \(v_n := v_{n,t_n}\), to simplify the notation. By (6.10), \(t_n \to 0\). Using (6.13) and (6.14), we get
\[
\lim_{n \to \infty} \|v_n - v\| = 0, \quad \lim_{n \to \infty} \|f(v_n) - v_n\| = 0.
\]
Taking \(X = E, \|\cdot\| = \|\cdot\|\), we see that assumptions (A1)(A3) of Lemma 6.5 are satisfied due to assumptions (A1)(A3) of Theorem 6.1. Thus, the conclusion of Lemma 6.5 contradicts (6.15). \(\square\)

Remark 6.7. The introduction of \(f_{s,t}\) as in (6.8) and the derivation of its properties is closely related to Lemma 2.1 on page 45 of [Nus88].

6.2. Geometric convergence to the fixed point. When \(\tilde{r}(f'_\mu) < 1\), we can prove a result more precise than Theorem 6.1: the geometric convergence of the orbits of \(f\) towards the fixed point of \(f\).

**Theorem 6.8.** Let \((V,d)\) be a complete metric space, \(G\) be a connected open subset of \(V\), \(f : G \to G\) be a nonexpansive map and \(v \in G\) be a fixed point of \(f\): \(f(v) = v\). Assume that assumptions (B1) and (A1) of Theorem 6.1 hold and that \(f'_\mu : E \to E\) satisfies \(\tilde{r}(f'_\mu) < 1\), where \(\tilde{r} = \tilde{r}_E\) is defined with respect to the \(\|\cdot\|\) norm. Then,
\[
\limsup_{k \to \infty} d(f^k(x), v)^{1/k} \leq \tilde{r}(f'_\mu) \quad \forall x \in G.
\]
In particular, the fixed point of \(f\) in \(G\) is unique.

*Remark 6.9.* Under the assumptions of Theorem 6.8, \(f'_\mu\) is nonexpansive (by Proposition 6.4), and, a fortiori, uniformly continuous on bounded sets of \(E\). Hence, using Proposition 5.3 with the assumption that \(\tilde{r}(f'_\mu) < 1\), we get that \(\text{Id} - f'_\mu\) has Property (F) and that the fixed point of \(f'_\mu\) is unique. This shows that assumptions (A2) and (A3) of Theorem 6.1 are satisfied. Therefore, Theorem 6.1 shows the uniqueness of the fixed point of \(f\) without the connectedness of \(G\), as soon as assumptions (B2) and (B3) on \((V,d)\) are satisfied.

To show Theorem 6.8 we first prove that there is a neighborhood of \(v\) in which all orbits of \(f\) converge geometrically to \(v\):

**Lemma 6.10.** Let \(V,d,G,f\) and \(v\) be as in Theorem 6.8, and let \((E,\|\cdot\|)\) be as in (B1). For all \(1 > \mu > \tilde{r}(f'_\mu)\), there exists \(\eta > 0\) and \(m > 0\) such that
\[
d(f^m(x), v) \leq \mu^m d(x,v) \quad \forall x \in B(v,\eta).
\]

*Proof.* Since \(\mu > \tilde{r}(f'_\mu)\), and \(\tilde{r}(f'_\mu)\) is defined in \((E,\|\cdot\|)\), we can choose \(m\) such that \(\|(f'_\mu)^m\| < \mu^m\). The chain rule for semidifferentiable maps (Lemma 3.4), together with \(f(v) = v\), show that \(f^m\) is semidifferentiable at \(v\), with \((f^m)'_v = (f'_\mu)^m\):
\[
f^m(x) - v = f^m(x) - f^m(v) = (f'_\mu)^m(x-v) + o(\|x-v\|).
\]
Hence,
\[
\|f^m(x) - v\| \leq \|(f'_\mu)^m\|\|x-v\| + o(\|x-v\|),
\]
and using (6.11), we get that there is a ball $B(v, \eta)$, with $\eta > 0$, in which (6.16) holds.

**Proof of Theorem 6.8** We get from (6.16):

(6.18) \[ d(f^m(v), v) \leq \mu^m d(x, v) \quad \forall k \geq 0, \ x \in B(v, \eta) . \]

Moreover, by the nonexpansiveness of $f$,

(6.19) \[ d(f^{k+1}(x), v) = d(f^{k+1}(x), f^{k+1}(v)) \leq d(f^k(x), f^k(v)) = d(f^k(x), v) . \]

Combining (6.18) and (6.19), we see that

(6.20) \[ \limsup_k d(f^k(x), v)^{1/k} \leq \mu \quad \forall x \in B(v, \eta) . \]

Let

$$\Omega = \{ x \in G \mid \lim_k f^k(x) = v \} .$$

We claim that $\Omega = G$. By (6.20), $B(v, \eta) \subset \Omega$, hence $\Omega \neq \emptyset$. We will show that $\Omega$ is both open and closed in $G$. We claim that

(6.21) \[ B(x, \eta/2) \cap G \subset \Omega \quad \forall x \in \Omega . \]

Indeed, if $x \in \Omega$, we have $d(f^n(x), v) < \eta/2$ for some $n$. Hence, for all $y \in G$ such that $d(y, x) \leq \eta/2$, $d(f^n(y), v) \leq d(f^n(y), f^n(x)) + d(f^n(x), v) < \eta$, and by (6.20), $\lim_k f^k(y) = v$, which shows (6.21), and, a fortiori, that $\Omega$ is open. Property (6.21) also implies that $\Omega$ is closed. Indeed, if $\langle x_n \in \Omega \mid n \geq 1 \rangle$ is a sequence converging to $x \in G$, we have $d(x_n, x) < \eta/2$ for some $n \geq 1$, hence, $x \in \Omega$ by (6.21). We have shown that $\Omega$ is nonempty, closed and open in $G$, and since $G$ is connected, $\Omega = G$. Finally, since $\lim_k f^k(x) = v$ for all $x \in G$, and since (6.20) holds, we have $\limsup_k d(f^k(x), v)^{1/k} \leq \mu$, for all $x \in G$. Since this inequality holds for all $\mu > \tilde{r}(f'_v)$, we have proved the convergence in Theorem 6.8 which itself implies that $v$ is the unique fixed point of $f$ in $G$. \qed

7. Fixed points and eigenvectors of semidifferentiable nonexpansive maps over normal cones

In this section, we derive from Theorem 6.1 some uniqueness results for fixed points or eigenvectors of maps acting on cones, as well as geometric convergence results for the orbits.

As a first application, we get the following uniqueness result for the fixed point of a nonexpansive map in the Thompson metric.

**Theorem 7.1** (Uniqueness of fixed points). Let $C$ be a normal cone with nonempty interior in a Banach space $(X, \| \cdot \|)$. Let $G$ be an open subset of $(X, \| \cdot \|)$ included in $C$ and $f : G \to \text{int} C$ be a nonexpansive map with respect to Thompson’s metric $d$. Let $v \in G$ be a fixed point of $f$: $f(v) = v$. Make the following assumptions:

(A1) $f$ is semidifferentiable at $v$.

(A2) The map $\text{Id} - f'_v : X \to X$ has Property (F).

(A3) The fixed point of $f'_v : X \to X$ is unique: $f'_v(x) = x, x \in X \Rightarrow x = 0$.

Then, the fixed point of $f$ in $G$ is unique: $f(w) = w, w \in G \Rightarrow w = v$. 

License or copyright restrictions may apply to redistribution; see https://www.ams.org/journal-terms-of-use
Proof. We apply Theorem 6.1. Let $V = \text{int } C$ endowed with $\tilde{d}$. Since $v \in \text{int } C$, $C_v = \text{int } C = V$, and by Proposition 2.1 $(V, \tilde{d})$ is a complete metric space. Moreover, by Proposition 2.1 $||| \cdot |||_v$ and $\tilde{d}$ define the same topology on $V$, hence the set $G$ is open in $(V, \tilde{d})$. Since the equivalence (2.23) holds, $(V, \tilde{d})$ satisfies (B1) with $E = X_v$ and $||| \cdot ||| = ||| \cdot |||_v$. From the definition of $\tilde{d}$ and the convexity of $C$, it follows that the metric space $(V, \tilde{d})$ satisfies assumption (B2). Assumption (B3) for $(V, \tilde{d})$ follows from the existence of a (minimal) geodesic for $\tilde{d}$ between any two points of $\text{int } C$, which is proved in [Nus88, Proposition 1.12, page 34]. The map $f$ is nonexpansive with respect to $\tilde{d}$ and $v$ is a fixed point of $f$. Then, assumptions (A1)–(A3) of Theorem 7.1 correspond to assumptions (A1)–(A3) of Theorem 6.1, respectively, which yields the conclusion of the theorem.

Theorem 7.2 (Geometric convergence). Let $C$ be a normal cone with nonempty interior in a Banach space $(X, ||| \cdot |||)$, and let $G$ be an open subset of $(X, ||| \cdot |||)$ included in $C$. Assume that $f : G \to G$ is nonexpansive with respect to Thompson’s metric $\tilde{d}$. If $f$ has a fixed point $v \in G$, and if $f$ is semidifferentiable at $v$, with $\tilde{r}(f'_v) < 1$, where $\tilde{r}$ is defined with respect to the $||| \cdot |||$ or the $||| \cdot |||_v$ norm, then the fixed point of $f$ in $G$ is unique. Moreover, if $G$ is connected, we have:

$$\forall x \in G, \quad \limsup_{k \to \infty} \tilde{d}(f^k(x), v)^{1/k} \leq \tilde{r}(f'_v).$$

Proof. By the proof of Theorem 7.1 $(\text{int } C, \tilde{d})$ satisfies (B1). By Proposition 6.4, $f'_v$ is nonexpansive, and, a fortiori, uniformly continuous on bounded sets of $C$. Therefore, Proposition 5.4 implies that assumptions (A2) and (A3) of Theorem 7.1 are satisfied. Since the other assumptions of Theorem 7.2 imply the other assumptions of Theorem 7.1 we get the first assertion of Theorem 7.2 (See also Remark 6.9). The last one is a direct corollary of Theorem 6.8.

Theorem 7.3 (Uniqueness of fixed points in $\Sigma$). Let $C$ be a normal cone with nonempty interior in a Banach space $(X, ||| \cdot |||)$, let $\psi \in C^* \setminus \{0\}$, and let $\Sigma = \{x \in \text{int } C \mid \psi(x) = 1\}$. Let $G$ be a relatively open subset of $\Sigma$ and $g : G \to \Sigma$ be a nonexpansive map with respect to Hilbert’s projective metric $\tilde{d}$ or Thompson’s metric $\tilde{d}$. Let $v \in G$ be a fixed point of $g$: $g(v) = v$. Make the following assumptions:

(A1) $g$ is semidifferentiable at $v$ with respect to $\psi^{-1}(0)$.

(A2) The map $\text{Id} - g'_v : \psi^{-1}(0) \to \psi^{-1}(0)$ has Property (F).

(A3) The fixed point of $g'_v : \psi^{-1}(0) \to \psi^{-1}(0)$ is unique: $g'_v(x) = x, x \in \psi^{-1}(0) \Rightarrow x = 0$.

Then, the fixed point of $g$ in $G$ is unique: $g(w) = w, w \in G \Rightarrow w = v$.

Proof. We apply Theorem 6.1. Let $V = -v + \Sigma$. We consider on $V$ the two metrics $d_v(x, y) := \tilde{d}(v + x, v + y)$ and $\bar{d}_v(x, y) := \tilde{d}(v + x, v + y)$. Let $G_v = -v + G$ and consider the map $f : G_v \to V$, $f(x) = g(v + x) - v$. If $g$ is nonexpansive with respect to $d$ (resp. $\tilde{d}$), then $f$ is nonexpansive with respect to $d_v$ (resp. $\bar{d}_v$), and satisfies $f(0) = 0$.

We know, by Proposition 2.2 that $(\Sigma, d)$ and $(\Sigma, \bar{d})$; hence $(V, d_v)$ and $(V, \bar{d}_v)$ are complete metric spaces. Since $v \in \text{int } C$, Proposition 2.1 together with (2.4), (2.8), and (2.9), show that $||| \cdot |||$, $\omega_v$, $||| \cdot |||_v$, $d$ and $\tilde{d}$ define the same topology on $\Sigma$. Hence, $||| \cdot |||$, $\omega_v$, $||| \cdot |||_v$, $d_v$ and $\bar{d}_v$ define the same topology on $V$. Since the equivalence (2.24) (resp. (2.23)) holds, $(V, d_v)$ (resp. $(V, \bar{d}_v)$) satisfies (B1) with $E = \psi^{-1}(0)$ and $||| \cdot ||| = \omega_v$ (resp. $||| \cdot ||| = ||| \cdot |||_v$). Moreover, the set $G_v$ is open in $(V, d_v)$.
and \((V, \bar{d}_v)\). From the definition of \(d, \bar{d}\) and the convexity of \(C\), it follows that the metric spaces \((V, d_v)\) and \((V, \bar{d}_v)\) both satisfy assumption \([B2]\) Assumption \([B3]\) for \((V, d_v)\) (resp. \((V, \bar{d}_v)\)) follows from the existence of a (minimal) geodesic for \(d\) (resp. \(\bar{d}\)) between any two points of \(\Sigma_v\), which is proved in \[\text{Proposition 1.9, page 25}] (resp. \[\text{Proposition 1.12, page 34}]\). Then, assumptions \([A1]\)–\([A3]\) of Theorem 7.3 correspond to assumptions \([A1]\)–\([A3]\) of Theorem 6.1 which yields the conclusion of Theorem 7.3. 

\[\square\]

Remark 7.4. The proof of Theorem 7.5 remains valid if one replaces \(\text{int } C\) by the cone \(C_u\) for some \(u \in C \setminus \{0\}\) where \(C\) is still a normal cone, while assuming that \(G\) is an open subset of \((C_u, \bar{d})\), and replacing \(\| \cdot \|\) by \(\| \cdot \|_u\). Similarly, the statements of Theorem 7.3, and also of Theorem 7.5 and Corollaries 7.7, 9.1, and 9.3 below, have obvious extensions applying to \(C_u\) or \(\Sigma_u\).

In order to obtain a uniqueness result for an eigenvector of \(f\), we shall apply Theorem 7.5 to the map \(g\) introduced in Lemma 4.3. Natural assumptions on \(f\) which ensure the nonexpansiveness of \(g\) together with assumptions \([A1]\)–\([A3]\) in Theorem 7.3 are captured in the following result.

**Theorem 7.5** (Uniqueness of eigenvectors in \(\Sigma\)). Let \(C\) be a normal cone with nonempty interior in a Banach space \((X, \| \cdot \|)\), let \(\psi \in C^* \setminus \{0\}\), and denote \(\Sigma = \{x \in \text{int } C \mid \psi(x) = 1\}\). Let \(G\) be an open subset of \((X, \| \cdot \|)\) included in \(C\) and \(f : G \to \text{int } C\) be a map such that \(f|_{G\cap \Sigma}\) is nonexpansive with respect to Hilbert’s projective metric \(d\). Assume that \(v \in G \cap \Sigma\) is a fixed point of \(f\): \(f(v) = v\). Make the following assumptions:

\begin{enumerate}
\item [(A1)] \(f\) is semidifferentiable at \(v\).
\item [(A2)] The map \((\text{Id} - f'_v)|_{\psi^{-1}(0)} : \psi^{-1}(0) \to X\) has Property (F).
\item [(A3)] The fixed point of \(f'_v\) in \(\psi^{-1}(0)\) is unique: \(f'_v(x) = x, x \in \psi^{-1}(0) \implies x = 0\).
\item [(A4)] \(f'_v\) is order preserving.
\item [(A5)] \(f'_v\) is additively subhomogeneous with respect to \(v\).
\end{enumerate}

Then, the eigenvector of \(f\) in \(G \cap \Sigma\) is unique: \(\exists \lambda > 0, f(w) = \lambda w, w \in G \cap \Sigma \implies w = v\).

**Proof.** Let \(\tilde{f} : G \to \Sigma\) be defined by \((4.3)\), \(\tilde{f}(x) = \frac{f(x)}{\psi(f(x))}\), and \(g = \tilde{f}|_{G\cap \Sigma} : G \cap \Sigma \to \Sigma\). We shall prove that \(g\) satisfies the assumptions of Theorem 7.3 with \(G\) replaced by \(G \cap \Sigma\). First, since \(f|_{G\cap \Sigma}\) is nonexpansive with respect to \(d\), so is \(g\) (by Lemma 4.4). Since \(f(v) = v\) and \(v \in G \cap \Sigma, g(v) = v\). From assumption \([A1]\) of Theorem 7.3 and Lemma 4.4, we get assumption \([A1]\) of Theorem 7.3. It remains to check assumptions \([A2]\) and \([A3]\) of Theorem 7.3.

Let us first show that

\[\|x - f'_v(x)\|_v \leq 2\|x - g'_v(x)\|_v \quad \forall x \in \psi^{-1}(0).\]  

Since \(f'_v(0) = 0\) and, by \([A4]\) and \([A5]\), \(f'_v\) is order preserving and additively subhomogeneous with respect to \(v\), \(h = f'_v\) satisfies the assumptions of Lemma 4.5 with \(S \supseteq 0\). Hence, from \((4.9)\) and \((4.10)\), we obtain, for all \(x \in X\),

\[m(x - f'_v(x) / v) \leq m(x / v) \lor 0,\]

\[M(x - f'_v(x) / v) \geq M(x / v) \land 0.\]

Since \(\psi \in C^*, v \in \Sigma\) and \(m(x / v)v \leq x \leq M(x / v)v\), we get \(m(x / v) \leq \psi(x) \leq M(x / v)\). Hence, for all \(x \in \psi^{-1}(0)\), \(m(x / v) \leq 0 \leq M(x / v)\), which with \((7.2)\)
and \((\ref{7.3})\) leads to
\begin{equation}
    m(x - f'_v(x) / v) \leq 0 \leq M(x - f'_v(x) / v).
\end{equation}
Denote \(y = x - g'_v(x)\). By \((\ref{4.7})\) and \(g'_v = \tilde{f}'_v|_{\psi^{-1}(0)}\), we get
\begin{equation}
    x - f'_v(x) = y - \psi(f'_v(x))v;
\end{equation}
thus \(m(x - f'_v(x) / v) = m(y / v - \psi(f'_v(x)))\) and \(M(x - f'_v(x) / v) = M(y / v - \psi(f'_v(x)))\). Using \((\ref{7.4})\), we get \(m(y / v) \leq \psi(f'_v(x)) \leq M(y / v)\), and hence
\begin{equation}
    |\psi(f'_v(x))| \leq \|y\|_v.
\end{equation}
Gathering \((\ref{7.3})\) and \((\ref{7.6})\), we get
\[\|x - f'_v(x)\|_v \leq \|y\|_v + |\psi(f'_v(x))| \leq 2\|y\|_v,\]
which shows \((\ref{7.1})\).

Using \((\ref{7.1})\), we get that if \(g'_v(x) = x\) and \(x \in \psi^{-1}(0)\), then \(f'_v(x) = x\), whence by assumption \((A3)\) in Theorem \((\ref{7.5})\) \(x = 0\). This shows assumption \((A3)\) in Theorem \((\ref{7.3})\).

Now let \(\langle x_j \mid j \geq 1 \rangle\) be a bounded sequence in \(\psi^{-1}(0)\) such that \(x_j - g'_v(x_j) \to j \to \infty 0\). By \((\ref{7.1})\), this implies that \(x_j - f'_v(x_j) \to j \to \infty 0\), whence, by assumption \((A2)\) of Corollary \((\ref{7.7})\) \(\langle x_j \mid j \geq 1 \rangle\) admits a convergent subsequence. This shows assumption \((A2)\) of Theorem \((\ref{7.3})\) and completes the verification of the assumptions of this theorem.

If \(w \in G \cap \Sigma\) satisfies \(f(w) = \lambda w\) for some \(\lambda > 0\), then \(g(w) = w\); hence, by Theorem \((\ref{7.3})\) \(w = v\).

**Remark 7.6.** As a consequence of Lemma \((\ref{4.2})\) assumption \((A4)\) of Theorem \((\ref{7.3})\) is fulfilled as soon as \(f\) is order preserving in a neighborhood of \(v\), and assumption \((A5)\) is fulfilled as soon as \(f\) is subhomogeneous in a neighborhood of \(v\). These properties also imply, by Lemma \((\ref{4.1})\), that \(f|_{G \cap \Sigma}\) is nonexpansive with respect to Hilbert’s projective metric \(d\). They will be used in particular in Corollary \((\ref{7.7})\). Another way to ensure \((A5)\) is given by Lemma \((\ref{4.3})\). In particular, \((A5)\) is fulfilled when \(f'_v\) is linear (that is, \(f\) is differentiable at \(v\)) and \(f'_v(v) \leq 0\). Moreover, by Lemma \((\ref{4.2})\) \((i)\) assumption \((A5)\) is fulfilled when \(f\) is convex and \(f'_v(v) \leq 0\).

**Corollary 7.7.** (Uniqueness of eigenvectors). Let \(C\) be a normal cone with nonempty interior in a Banach space \((X, \|\cdot\|)\). Let \(f : \text{int} C \to \text{int} C\) be homogeneous and order preserving. Let \(S = \{x \in \text{int} C \mid f(x) = x\}\), and assume that \(v \in S\). Make the following assumptions:

- \((A1)\) \(f\) is semidifferentiable at \(v\).
- \((A2)\) The map \(\text{Id} - f'_v : X \to X\) has Property \((F)\).
- \((A3)\) If \(f'_v(x) = x\) for some \(x \in X\), then \(x \in \{\lambda v \mid \lambda \in \mathbb{R}\}\).

Then, \(S = \{\lambda v \mid \lambda > 0\}\).

**Proof.** Let us first check that \(f\) satisfies the assumptions of Theorem \((\ref{7.5})\). Consider \(G = \text{int} C\), which is clearly open. Since \(v \in C \setminus \{0\}\), one can choose \(\psi \in C^* \setminus \{0\}\) such that \(\psi(v) = 1\). In that case, \(v, \psi \in \Sigma = G \cap \Sigma\) and \(f(v) = v\). Since \(f\) is order preserving and homogeneous, \(f|_{\Sigma}\) is nonexpansive with respect to \(d\), by Lemma \((\ref{4.1})\) \((i)\). Assumption \((A1)\) of Corollary \((\ref{7.7})\) corresponds to assumption \((A1)\) of Theorem \((\ref{7.5})\). Assumption \((A2)\) of Corollary \((\ref{7.7})\) implies assumption \((A2)\) of Theorem \((\ref{7.5})\). In order to show assumption \((A3)\) of Theorem \((\ref{7.5})\) let us consider \(x \in X\) such that \(f'_v(x) = x\) and \(\psi(x) = 0\). By assumption \((A3)\) of Corollary \((\ref{7.7})\) \(x = \lambda v\) for some \(\lambda \in \mathbb{R}\), and since \(\psi(x) = 0\), we get \(\lambda = 0\), thus \(x = 0\), which shows
assumption [A3] of Theorem 7.5. Assumptions [A4] and [A5] of Theorem 7.5 are deduced from Lemma 1.2 [ii] and (iii) respectively, using the fact that $f$ is order preserving and homogeneous. This completes the proof of the assumptions of Theorem 7.5.

Let $x \in S$; then $\lambda = \psi(x) > 0$, and, since $f$ is homogeneous, $y = \frac{x}{\lambda}$ satisfies $f(y) = y$ and $y \in \Sigma$. From Theorem 7.5 this implies $y = v$; hence $x = \lambda v$. Conversely, if $x = \lambda v$ for some $\lambda > 0$, then $x \in S$, since $f$ is homogeneous. □

If $f$ is homogeneous, $f(v) = v$ and $f$ satisfies assumption [A1] of Corollary 7.7 we have trivially $f'_v(\lambda v) = \lambda v$, for all $\lambda \in \mathbb{R}$. Therefore, assumption [A3] of Corollary 7.7 can be thought of as a uniqueness assumption for the eigenvector of $f'_v$, and Corollary 7.7 states in essence that the uniqueness of the eigenvector of $f'_v$ implies the uniqueness of the eigenvector of $f$.

Let us state a corollary of Theorem 6.8 in the framework of Corollary 7.7. If $X$ is a vector space endowed with a seminorm $\omega$ and $h$ is a homogeneous self-map of a cone $C$ of $X$, we generalize (3.7) and (5.1) by setting

$$\omega_C(h) = \sup_{x \in C, \omega(x) \neq 0} \frac{\omega(h(x))}{\omega(x)} = \sup_{x \in C, \omega(x) = 1} \omega(h(x)) \in [0, +\infty]$$

and

$$\tilde{r}_C(h) = \lim_{k \to \infty} \omega_C(h^k)^{1/k}.$$ 

Again, when $C = X$, we omit $C$ in these notation.

**Theorem 7.8.** Let $C$ be a normal cone with nonempty interior in a Banach space $(X, \| \cdot \|)$. Let $f : \text{int} C \to \text{int} C$ be homogeneous and order preserving. Let $S = \{ x \in \text{int} C \mid f(x) = x \}$, and assume that $v \in S$. Assume that $f$ is semidifferentiable at $v$ with $\tilde{r}(f'_v) < 1$, where $\tilde{r}$ is defined as in (7.7), (7.8) with respect to the seminorm $\omega_v$. Then, for all $x \in \text{int} C$,

$$\limsup_{k \to \infty} d(f^k(x), v)^{1/k} \leq \tilde{r}(f'_v),$$

where $d$ is Hilbert’s projective metric, and there is a scalar $\lambda > 0$ (depending on $x$) such that

$$\limsup_{k \to \infty} \tilde{d}(f^k(x), \lambda v)^{1/k} \leq \tilde{r}(f'_v),$$

where $\tilde{d}$ is Thompson’s metric.

**Proof.** Consider as in the proof of Corollary 7.7 $G = \text{int} C$ and $\psi \in C^* \setminus \{0\}$ such that $\psi(v) = 1$. Denote again $\Sigma = \{ x \in \text{int} C \mid \psi(x) = 1 \}$. Since $f$ is homogeneous, the functions $\tilde{f}$ of (4.6) and $g = \tilde{f}|_{\Sigma}$ satisfy

$$f^k(x) = \psi(f^k(x))\tilde{f}^k(x)$$

and

$$\tilde{f}^k(x) = g^k \left( \frac{x}{\psi(x)} \right).$$

Hence

$$d(f^k(x), v) = d \left( g^k \left( \frac{x}{\psi(x)} \right), v \right).$$
Moreover, by Lemma 14.2 (iii) \( f'_v \) is additively homogeneous with respect to \( v \), and using (4.7), we get by induction on \( k \):

\[
(7.12) \quad \tilde{f}'_v(x) = (f'_v(x) - \psi((f'_v)k(x)))v = (g'_v)k(x - \psi(x)v).
\]

Indeed, for any \( y \in G \), \( \tilde{f}'_v(y) \) is the unique vector in \( \psi^{-1}(0) \) of the form \( f'_v(y) - \lambda v \) with \( \lambda \in \mathbb{R} \). In particular \( (f'_v)^{k+1}(x) \) is the unique element of \( \psi^{-1}(0) \) of the form \( f'_v((f'_v)^k(x)) - \lambda v \). If \( (7.12) \) holds for \( k \), then using the property that \( f'_v \) is additively homogeneous with respect to \( v \), we get that \( (f'_v)^{k+1}(x) = (f'_v)^{k+1}(x) - \lambda' v \) for some \( \lambda' \in \mathbb{R} \), and since it belongs to \( \Sigma \) we deduce \( (7.12) \) for \( k + 1 \). Hence

\[
\omega_v((f'_v)^k(x)) = \omega_v((\tilde{f}'_v)^k(x)) = \omega_v((g'_v)^k(x - \psi(x)v)).
\]

Therefore,

\[
\omega((f'_v)^k) = \sup_{x \in X} \frac{\omega_v((g'_v)^k(x - \psi(x)v))}{\omega_v(x - \psi(x)v)} = \sup_{x \in \psi^{-1}(0)} \frac{\omega_v((g'_v)^k(x))}{\omega_v(x)} = \omega((g'_v)^k),
\]

which shows that

\[
(7.13) \quad \tilde{r}(f'_v) = \tilde{r}(g'_v).
\]

From (7.14) and (7.13), (7.3) is equivalent to

\[
(7.15) \quad \forall x \in \Sigma, \limsup_{k \to \infty} d(g^k(x), v)^{1/k} \leq \tilde{r}(g'_v).
\]

Since \( \omega_v \) is a norm on \( \psi^{-1}(0) \) and \( g : \Sigma \to \Sigma \) is nonexpansive with respect to \( d \) (by Lemma 4.4), (7.11) is obtained by applying Theorem 6.8 using the same transformations as in the first paragraph of the proof of Theorem 7.3.

We now prove (7.10). By homogeneity of \( f \), it is enough to consider the case when \( x \in \Sigma \). Then, since \( \tilde{d} \) and \( \bar{d} \) are equivalent on \( \Sigma \), we get by (7.14) and (7.3),

\[
(7.15) \quad \limsup_{k \to \infty} \tilde{d}(g^k(x), v)^{1/k} \leq \tilde{r}(g'_v) = \tilde{r}(f'_v) < 1.
\]

To derive (7.10) from (7.15), we write \( f^k(x) \) as a function of the orbit of \( x \) under \( g \),

\[
(7.16) \quad f^k(x) = \psi(f \circ g^{k-1}(x)) \cdots \psi(f \circ g^0(x))g^k(x)
\]

(this formula is readily checked by induction on \( k \geq 1 \), using the homogeneity of \( f \) and the definition of \( g \); this is an instance of the well known “1-cocycle” representation of iterates of homogeneous maps; see e.g. [Fur63]). We still denote by \( \tilde{d} \) Thompson’s metric on the open cone of strictly positive real numbers:

\[
\tilde{d}(\nu, \mu) = |\log \nu - \log \mu|, \quad \forall \nu, \mu > 0.
\]

Since \( f \) is order preserving and homogeneous, and since \( x \leq y \Rightarrow \psi(x) \leq \psi(y) \) and \( \psi \) is linear, we have:

\[
(7.17) \quad \forall x, y \in \text{int } C, \tilde{d}(\psi \circ f(x), \psi \circ f(y)) \leq \tilde{d}(x, y).
\]

(This follows from the standard argument of the proof of Lemma 4.1. we have \( \exp(-\tilde{d}(x, y))y \leq x \leq \exp(\tilde{d}(x, y))y \), by definition of Thompson’s metric, and applying \( \psi \circ f \), we get (7.17).) Let \( \mu_k = \psi(f \circ g^k(x)) \). Since \( f(v) = v \) and \( \psi(v) = 1 \), it follows from (7.17) that

\[
|\log \mu_k| = \tilde{d}(\mu_k, 1) = \tilde{d}(\psi \circ f(g^k(x)), \psi \circ f(v)) \leq \tilde{d}(g^k(x), v).
\]
Using (7.15), we deduce:
\[
\limsup_{k \to \infty} |\log \mu_k|^{1/k} \leq \tilde{r}(g_v') < 1.
\]
Hence, the series $\sum_{k=0}^{\infty} \log \mu_k$ is absolutely convergent, which implies that the infinite product $\lambda = \prod_{k=0}^{\infty} \mu_k$ is convergent (with $\infty > \lambda > 0$). We get from (7.16):
\[
d(f^k(x), \lambda v) = d\left(\prod_{0 \leq m \leq k-1} \mu_m g^k(x), \lambda v\right)
\leq d\left(\prod_{0 \leq m \leq k-1} \mu_m g^k(x), \lambda g^k(x)\right) + d(\lambda g^k(x), \lambda v)
\leq (\sum_{m \geq k} |\log \mu_m|) + d(g^k(x), v),
\]
and combining (7.18) with (7.15), we get (7.10). \hfill \Box

8. Fixed points and eigenvectors of semidifferentiable nonexpansive maps over proper cones

As pointed out in Remark 6.3, the map $f : \mathcal{C}_0([0,1]) \to \mathcal{C}_0([0,1])$ defined by $f(x)(t) = x(\frac{1}{2}) \lor (x(t) - 1)$ and which has $v \equiv 0$ as a unique fixed point, is such that $\text{Id} - f'_v$ has Property (F) on the Banach space $C^\gamma_0 ([0,1])$ of Hölder continuous functions $x : [0,1] \to \mathbb{R}$ with exponent $\gamma$, such that $x(0) = 0$. Indeed, since $f'_v$ is linear in this case, it suffices to prove, as noted in Section 7.2, that $f'_v$ such that $f'_v(x)(t) = x(\frac{1}{2})$ is Fredholm of index 0. However, this is a special case of results which are proved for a much more general class of linear maps in [Nus01, Section 5]. Alternately, in this simple case, the reader can try a direct proof. Since the positive cone of $C^\gamma_0 ([0,1])$ is not a normal cone, but only a proper cone, the results of Section 7 cannot be used. In order to treat this case, we thus need to prove a result similar to that of Section 7 but under the less restrictive condition that $C$ is proper. The results of Section 6 cannot be applied. We are instead using condition (A2) below, which will allow degree theory arguments (see [MPN02]).

**Theorem 8.1.** Let $C$ be a proper cone with nonempty interior in a Banach space $(X, \| \cdot \|)$. Let $\psi \in C^* \setminus \{0\}$, and denote $\Sigma = \{ x \in \text{int} C \mid \psi(x) = 1 \}$. Let $G$ be a relatively open subset of $\Sigma$ and let $g : G \to \Sigma$ be continuous and nonexpansive with respect to Hilbert’s projective metric $d$. Assume that $v \in G$ is a fixed point of $g$. Make the following assumptions:

(A1) $g$ is semidifferentiable at $v$.

(A2) There exists a relatively open neighborhood $U$ of $v$ in $\Sigma$, $U \subset G$, and a homogeneous generalized measure of noncompactness $\nu$ on $X$, such that $g_U$ is a $k$-set contraction with $k < 1$ with respect to $\nu$.

(A3) The fixed point of $g_v' : \psi^{-1}(0) \to \psi^{-1}(0)$ is unique: $x = g_v'(x), x \in \psi^{-1}(0) \Rightarrow x = 0$.

Then, $v$ is the only fixed point of $g$ in $G$: $g(w) = w, w \in G \implies w = v$.

The following lemma is the key result needed to prove Theorem 8.1.

**Lemma 8.2.** Let the assumptions and notation be as in Theorem 8.1. If $w \in \Sigma$, define, for $0 \leq t \leq 1$, $g_t : G \to \Sigma$ by $g_t(y) = (1-t)g(y) + tw$. Given $\epsilon > 0$, there
exists $\delta > 0$ such that for $0 \leq t \leq \delta$, there exists $y_t \in G$ with $\|y_t - v\| \leq \epsilon$ and $g_t(y_t) = y_t$.

Proof. Define $h_t := g_t(v + x) - v$ for $x \in G_0 := -v + G \subset \psi^{-1}(0)$ and $t \in [0, 1]$. By assumption \((A2)\) of Theorem 8.1, \(g_U\) is a k-set contraction with respect to \(\nu\), and so is \((g_t)_U\) for $0 \leq t \leq 1$ (indeed from \((5.4)\), any translation of a k-set contraction is a k-set contraction, and from \((5.3d)\) any homothetic transformation with factor $\leq 1$ of a k-set contraction is a k-set contraction). Then, $h_t$ is a k-set contraction when restricted to the open neighborhood $-u + U$ of 0 in $\psi^{-1}(0)$. So $(h_t)_0 = (g_t)_0 = (1 - t)g'_v$, the semidifferential of $h_t$ at 0, is a k-set contraction on $(\psi^{-1}(0), \|\cdot\|)$ (this follows from \((5.3a)\)).

Since $g_0(v) = v$, we need to show that for $t > 0, t$ small, $h_t(x) = x$ has a solution in $B_\epsilon(0) := \{z \in \psi^{-1}(0) \mid \|z\| \leq \epsilon\}$ (one may assume that $\epsilon$ is such that $B_\epsilon(0) \subset G_0$). For any fixed $t > 0$, we consider the homotopy:

$$Id - f_{t,\lambda}, \quad 0 \leq \lambda \leq 1,$$

with

$$f_{t,\lambda}(x) = (1 - \lambda)h_t(x) + \lambda(h_t)_0(x), \quad x \in B_\epsilon(0), \quad 0 \leq t \leq 1, \quad 0 \leq \lambda \leq 1.$$

Recall that, since $g$ is semidifferentiable at $v$, with semidifferential $g'_v$,

$$g(v + x) = v + g'_v(x) + R(x),$$

where $\|R(x)\| \leq \eta(\|x\|)\|x\|$ and $\lim_{s \to 0^+} \eta(s) = 0$. It follows that

$$x - f_{t,\lambda}(x) = x - (1 - \lambda)(g'_v(x) + R(x) + tw - tg(v + x)) - \lambda(1 - t)g'_v(x)$$

$$= x - g'_v(x) - (1 - \lambda)R(x) - (1 - \lambda)t(w - g(v + x)) + \lambda tg'_v(x).$$

For $\|x\| = 1, x \in \psi^{-1}(0)$, $x - g'_v(x) \neq 0$ by assumption \((A3)\). Because $g'_v = h'_0$ is a k-set contraction on $(\psi^{-1}(0), \|\cdot\|)$, it follows that there exists $c > 0$ such that

$$\|x - g'_v(x)\| \geq c \text{ for } \|x\| = 1, \quad x \in \psi^{-1}(0).$$

Indeed, by Lemma 5.3 $Id - g'_v$ has Property (F). Hence if, by way of contradiction, there exists a sequence $\langle x_n \mid n \geq 1 \rangle$ of $\psi^{-1}(0)$ such that $\|x_n\| = 1$ and $\lim_{n \to \infty} x_n - g'_v(x_n) = 0$, there exists a convergent subsequence. Thus, the limit satisfies $x - g'_v(x) = 0$ and $\|x\| = 1$, which contradicts assumption \((A3)\).

By the homogeneity of $g'_v$, it follows that

$$\|x - g'_v(x)\| \geq c\|x\|, \text{ for } x \in \psi^{-1}(0).$$

Select $\epsilon_1 \leq \epsilon, \epsilon_1 > 0$, so that $\eta(s) \leq c/2$ for $0 \leq s \leq \epsilon_1$. It follows that

$$\|x - g'_v(x) - (1 - \lambda)R(x)\| \geq \frac{c}{2}\|x\|, \text{ for } 0 \leq \|x\| \leq \epsilon_1, \quad x \in \psi^{-1}(0).$$

Since $g(v + x)$ and $g'_v(x)$ are bounded in norm on $B_{\epsilon_1}(0)$, it follows that there exists $\delta > 0$ so that

$$t\|w - g(v + x)\| + t\|g'_v(x)\| < \frac{\epsilon_1}{2}, \text{ for } \|x\| = \epsilon_1, \quad 0 \leq t \leq \delta.$$ 

Using this estimate, we see that, for $0 \leq t \leq \delta$, $\|x\| = \epsilon_1$ and $0 \leq \lambda \leq 1$,

$$x - f_{t,\lambda}(x) \neq 0.$$
Since $h_t$ and $(h_t)'_0$ are both continuous and $k$-set contractions, so is $f_{t,\lambda}$ for $0 \leq \lambda \leq 1$ (indeed, using (5.3b) and (5.3d), one shows easily that the convex combination of $k$-set contractions is a $k$-set contraction). Hence, by the homotopy property for degree theory for $k$-set contractions (see [Nus71, Nus72] for the case where $\nu = \alpha$ is the Kuratowski-Darbo generalized measure of noncompactness, and [Nus85, MPN02, MPN10, MPN11b] for any $\nu$), we have
\[
\deg(Id - h_t, H, 0) = \deg(Id - (h_t)'_0, H, 0),
\]
for all $0 \leq t \leq \delta$, where $H = \{z \in \psi^{-1}(0) \mid \|z\| < \epsilon_1\}$.

Because $g$ is nonexpansive with respect to $d$, by Lemma 4.2(viii) we know that $g'_\sigma$ is nonexpansive on $\psi^{-1}(0)$, with respect to the seminorm $\sigma_\psi$ defined by (2.7) (which is a norm on $\psi^{-1}(0)$). It follows that $x - \sigma(h_t)'_0(x) = x - \sigma(1-t)g'_\sigma(x) \neq 0$ for $0 < t \leq \delta$, $0 \leq \sigma \leq 1$, and $\|x\| = \epsilon_1$, $x \in \psi^{-1}(0)$.

By the homotopy property of degree theory again,
\[
\deg(Id - (h_t)'_0, H, 0) = \deg(Id - \sigma(h_t)'_0, H, 0) \quad \text{for } 0 \leq \sigma \leq 1
\]
\[
= \deg(Id, H, 0) = 1.
\]
It follows that, for $0 < t \leq \delta$, $\deg(Id - h_t, H, 0) = 1$ so there exists $x_t \in H$ with $x_t = h_t(x_t)$. \qed

Proof of Theorem 8.1 Suppose, by way of contradiction, that there exists $w \in G$ with $w \neq v$ and $g(w) = w$. Select $r > 0$ so that $\|w - v\| > r$. Define $g_t : G \to \Sigma$ by $g_t(y) = (1-t)g(y) + tw$. Take $\delta > 0$ (by Lemma 8.2) so that, for $0 \leq t \leq \delta$, there exists $y_t \in G$ such that $\|y_t - v\| \leq r$ and $g_t(y_t) = y_t$. Note that $g_t(w) = w$ too, and we know (see [Nus88], Lemma 2.1, p. 45) that
\[
d(g_t(z_1), g_t(z_2)) < d(z_1, z_2)
\]
if $0 < t \leq 1$ and $z_1, z_2 \in G$, $z_1 \neq z_2$. Taking $z_1 = y_t$, $z_2 = w$, $0 < t \leq \delta$, we obtain a contradiction. \qed

Remark 8.3. In our definition of a $k$-set contraction $f : D \to X$, $k < 1$, with respect to a homogeneous generalized measure of noncompactness $\nu$, we do not assume that $f$ is continuous in the norm topology of $X$. However in Theorem 8.1 we have added the hypothesis that $g$ is continuous in the norm topology. The reason for this restriction is that we use the theory of the fixed point index for $k$-set contractions, $k < 1$, and the standard development of that theory requires maps to be continuous in the norm topology. If the map $g$ in Theorem 8.1 was only assumed to be nonexpansive with respect to Hilbert’s projective metric $d$, then the continuity of $g$ in the norm topology of $X$ would have followed easily for a normal cone $C$ (from Proposition 2.4) but not for a general proper cone $C$. In fact, the assumption that $g$ in Theorem 8.1 is continuous in the norm topology is not necessary. We sketch the argument below, but for reasons of length, the details are omitted.

In the following we shall always assume that $C$, $(X, \| \cdot \|)$, $\psi$, and $\Sigma$ are as in the first two sentences of Theorem 8.1 and as usual $d$ will denote Hilbert’s projective metric on $\Sigma$. If $(y_n \mid n \geq 1)$ is a sequence of points in $\Sigma$ and $\lim_{n \to \infty} \|y_n - y\| = 0$, where $y \in \Sigma$, it is not hard to prove that $\lim_{n \to \infty} d(y_n, y) = 0$. Conversely, if $T = \{y_n \mid n \geq 1\} \subset \Sigma$ has a compact closure in the norm topology and there exists $y \in \Sigma$ such that $\lim_{n \to \infty} d(y_n, y) = 0$, one deduces that $\lim_{n \to \infty} \|y_n - y\| = 0$. Working in the norm topology, let $U$ be a relatively open subset of $\Sigma$ such that
clo $U \subset \Sigma$. Let $g : \text{clo} U \to \Sigma$ be a map which is continuous with respect to Hilbert’s projective metric $d$ on $\Sigma$, and is also a $k$-set contraction, $k < 1$, with respect to a homogeneous generalized measure of noncompactness $\nu$. Under these assumptions, we claim that $g$ is continuous in the norm topology, so the assumption of norm continuity in Theorem 8.1 is superfluous. Indeed, suppose $(x_n \mid n \geq 1)$ is a sequence in $\text{clo} U$ and that $\lim_{n \to \infty} \|x_n - x\| = 0$. By the remarks above, $\lim_{n \to \infty} d(x_n, x) = 0$. Since $g$ is continuous with respect to Hilbert’s projective metric $d$, $\lim_{n \to \infty} d(g(x_n), g(x)) = 0$. In particular, there exists $n_0 \geq 1$ such that, for all $n \geq n_0$, $g(x_n) \in \{y \in \Sigma \mid \frac{1}{2}g(x) \leq y \leq 2g(x)\}$, which is a norm closed subset of $\Sigma$. Let $S = \{x_n \mid n \geq 1\} \cup \{x\}$; then $S$ is compact in the norm topology, and thus $\nu(S) = 0$, so $\nu(g(S)) = 0$. Consider $T := \text{clo}(g(S))$; we get that $T$ is compact in the norm topology and $T \subset \Sigma$. Assume by contradiction that $\lim_{n \to \infty} \|g(x_n) - g(x)\| \neq 0$. Then, there exists $\epsilon > 0$ and a subsequence $n_i \to \infty$ such that $\|g(x_{n_i}) - g(x)\| \geq \epsilon$ for all $i \geq 1$. By the norm compactness of $T$, we can also assume that there exists $y \in \Sigma$ with $\|y - g(x)\| \geq \epsilon$ such that $\lim_{n \to \infty} \|g(x_{n_i}) - y\| = 0$. But our earlier remarks now imply that $\lim_{n \to \infty} d(g(x_{n_i}), y) = 0$, a contradiction. Hence $\lim_{n \to \infty} \|g(x_n) - g(x)\| = 0$, which shows that $g$ is continuous in the norm topology.

**Theorem 8.4.** Let $C$ be a proper cone with nonempty interior in a Banach space $(X, \|\cdot\|)$. Let $\psi \in C^* \setminus \{0\}$, and denote $\Sigma = \{x \in \text{int} C \mid \psi(x) = 1\}$. Let $G$ be a relatively open subset of $\Sigma$, and $g : G \to \Sigma$ be continuous and nonexpansive with respect to Hilbert’s projective metric $d$. Assume that $v \in G$ is a fixed point of $g$. Make the following assumptions:

(A1) $g$ is semidifferentiable at $v$.

(A2) There exists a relatively open neighborhood $U$ of $v$ in $\Sigma$, $U \subset G$, and an integer $n \geq 1$ such that $g^n|_U$ is a $k$-set contraction with $k < 1$. If $n > 1$, assume also that $g'_n$ is uniformly continuous on bounded sets of $\psi^{-1}(0)$.

(A3) The fixed point of $(g'_n)^n : \psi^{-1}(0) \to \psi^{-1}(0)$ is unique: $x = (g'_n)^n(x), x \in \psi^{-1}(0) \implies x = 0$.

Then, $v$ is the only fixed point of $g^n$ in $G$ (and hence the only fixed point of $g$ in $G$): $g^n(w) = w, w \in G \implies w = v$.

**Proof.** Let $n \geq 1$ be as in the theorem. When $n > 1$, the map $g^n$ is defined on some relatively open subset $G_n$ of $\Sigma$ (take $G_n = G \cap g^{-1}(G) \cap \cdots \cap g^{-(n-1)}(G)$), and since $g$ is semidifferentiable at $v$, $g(v) = v$ and $g'_n$ is uniformly continuous on bounded sets of $\psi^{-1}(0)$, applying the chain rule (Lemma 3.3) to $C_1 = C_2 = \psi^{-1}(0)$, we get that $g^n$ is semidifferentiable at $v$, with $(g^n)'_v = (g'_n)^n$. Applying Theorem 8.1 to $g^n$, we get the conclusion of Theorem 8.4.

9. Eigenvectors of differentiable nonexpansive maps on cones

In this section, we specialize the previous results to the case where $f$ is differentiable at the fixed point, and compare the results obtained in this way with the ones of [Nus88].

**Corollary 9.1.** (Uniqueness of eigenvectors in $\Sigma$, the differentiable case). Let $C$ be a normal cone with nonempty interior in a Banach space $(X, \|\cdot\|)$, let $\psi \in C^* \setminus \{0\}$, and denote $\Sigma = \{x \in \text{int} C \mid \psi(x) = 1\}$. Let $G$ be an open subset of $C$ and $f : G \to \text{int} C$ be a map such that $f|_{G \cap \Sigma}$ is nonexpansive with respect to Hilbert’s
projective metric $d$. Assume that $v \in G \cap \Sigma$ is a fixed point of $f$: $f(v) = v$. Make the following assumptions:

(A1) $f$ is differentiable at $v$.

(A2) The linear operator $(\text{Id} - f'_v)|_{\psi^{-1}(0)} : \psi^{-1}(0) \to X$ is semi-Fredholm with index in $\mathbb{Z} \cup \{-\infty\}$.

(A3) The fixed point of $f'_v$ in $\psi^{-1}(0)$ is unique: $f'_v(x) = x, x \in \psi^{-1}(0) \Rightarrow x = 0$.

(A4) $f'_v(C) \subset C$.

(A5) $f'_v(v) \leq v$.

Then, the eigenvector of $f$ in $G \cap \Sigma$ is unique: $\exists \lambda > 0, f(w) = \lambda w, w \in G \cap \Sigma \Rightarrow w = v$.

Proof. We only need to verify that $f$ satisfies assumptions (A1)–(A5) of Theorem 7.5. Clearly, assumption (A1) of Corollary 9.1 implies assumption (A1) of Theorem 7.5. Under this condition, $f'_v$ is linear, and hence, assumption (A2) of Theorem 7.5 is equivalent to assumption (A2) of Corollary 9.1 (see [Hör94 Proposition 19.1.3] or [Kat95 Chapter IV, Theorems 5.10 and 5.11]). Assumption (A3) of Theorem 7.5 is identical to assumption (A3) of Corollary 9.1. Since $f'_v$ is linear, $f'_v$ is order preserving if, and only if, $f'_v(x) \geq 0$ when $x \geq 0$, that is, $f'_v(C) \subset C$, which shows that assumption (A4) of Theorem 7.5 is equivalent to assumption (A4) of Corollary 9.1 when $f'_v$ is linear. Also, since $f'_v$ is linear, assumption (A5) of Corollary 9.1 easily implies assumption (A5) of Theorem 7.5 (one can also use Lemma 4.3). \hfill \square

Remark 9.2. The assumptions of Corollary 9.1 arise when specializing the ones of Theorem 7.5 to the case in which $f'_v$ is linear. However assumption (A2) can be replaced by the apparently more restrictive assumption that $\text{Id} - f'_v$ is Fredholm of index 0, or that $(\text{Id} - f'_v)|_{\psi^{-1}(0)}$ is Fredholm of index $-1$, without loss of generality.

Indeed, under the other assumptions, in particular when (A1)–(A4) and (A5) hold, and when $v$ is in the interior of $C$, we get that $f'_v$ is linear continuous, order preserving and satisfies $\text{cw}_C(f'_v) \leq 1$, where $\text{cw}_C(f'_v)$ is defined in (5.2) $(\text{cw}_C(f'_v) := \inf \{\lambda > 0 | \exists x \in \text{int} C, f'_v(x) = \lambda x\})$. From Lemma 5.1 it follows that $r_C(f'_v) \leq 1$, and since $f'_v$ is linear, we get that $r(f'_v) \leq 1$. Then for all $0 < t < 1$, $\text{Id} - tf'_v$ is one-one, and thus Fredholm of index 0.

Moreover, since $\ker \psi$ is closed and of codimension one, it follows from standard properties of Fredholm operators (see [Hör94 §19.1]) that $\text{Id} - f'_v : X \to X$ is semi-Fredholm if and only if $(\text{Id} - f'_v)|_{\psi^{-1}(0)} : \psi^{-1}(0) \to X$ is semi-Fredholm, and the index of $\text{Id} - f'_v$ is equal to the one of $(\text{Id} - f'_v)|_{\psi^{-1}(0)}$ plus 1. This implies that, under assumption (A2) $\text{Id} - f'_v$ is semi-Fredholm.

From the latter property, the fact that all operators $\text{Id} - tf'_v$ with $t < 1$ are Fredholm of index 0, and the continuity of the Fredholm index on the set of semi-Fredholm operators, we deduce that $\text{Id} - f'_v$ is Fredholm of index 0, or equivalently that $(\text{Id} - f'_v)|_{\psi^{-1}(0)}$ is Fredholm of index $-1$. Conversely, if $(\text{Id} - f'_v)|_{\psi^{-1}(0)}$ is Fredholm of index $-1$, then (A2) holds trivially.

We shall give now a corollary of Corollary 9.1 which partially extends [Nus88 Theorem 2.5]. For a bounded linear operator $L : X \to X$ on a Banach space $(X, \| \cdot \|)$, we denote by $r(L)$ the spectral radius of $L$, which coincides with the Bonsall spectral radius $\tilde{r}_X(L)$ in (5.1). We denote by $N(L)$ the null space of $L$. Let $C$ be a proper cone of $X$. We say that $L$ satisfies the weak Krein-Rutman (WKR) condition with respect to $C$ if $L(C) \subset C$, and either $r(L) = 0$ or $r := r(L) > 0$,
and (i) there exists \( u \in C \setminus \{0\} \) such that \( N(r \text{Id} - L) = \{ \lambda u \mid \lambda \in \mathbb{R} \} \), and (ii) \( r \text{Id} - L \) is a semi-Fredholm operator. The operator (WKR) is easier to check than the Krein-Rutman (KR) condition used in [Nus88, Definition 2.1], where condition (ii) is replaced by the condition that \( r \text{Id} - L \) is a Fredholm operator with index 0, and where it is also assumed that, when \( r > 0 \), \( L^* \) has an eigenvector \( u^* \in C^* \setminus \{0\} \) with eigenvalue \( r \) such that \( u^*(u) > 0 \). However, if (WKR) holds, then, by the same arguments as in Remark 9.2, if \( r := r(L) > 0 \), then, for all \( 0 < t < 1 \), \( r \text{Id} - tL \), and so \( r \text{Id} - L \), are necessarily Fredholm of index 0, as requested by the (KR) condition. Furthermore, a refinement of a theorem of Krein and Rutman (see [SW99]) implies that \( L^* \) has an eigenvector \( u^* \) in \( C^* \) with eigenvalue \( r \). Thus, the only difference in generality between condition (WKR) and condition (KR) is the requirement that \( u^*(u) > 0 \). Even if a variety of conditions imply that \( u^*(u) > 0 \), it may happen that \( u^*(u) = 0 \).

**Corollary 9.3 (Uniqueness of eigenvectors, the differentiable case).** Let \( C \) be a normal cone with nonempty interior in a Banach space \( (X, \| \cdot \|) \), let \( \psi \in C^* \setminus \{0\} \), and denote \( \Sigma = \{ x \in \text{int} C \mid \psi(x) = 1 \} \). Let \( G \) be an open subset of \( (X, \| \cdot \|) \) included in \( C \) and \( f : G \to \text{int} C \) be a map such that \( f |_{C \cap \Sigma} \) is nonexpansive with respect to Hilbert’s projective metric \( d \). Assume that \( v \in G \cap \Sigma \) is a fixed point of \( f \): \( f(v) = v \). Make the following assumptions:

(A1) \( f \) is differentiable at \( v \).

(A2) The linear operator \( f'_v \) satisfies the WKR condition with respect to \( C \).

(A3) If \( u \in C \setminus \{0\} \) is an eigenvector of \( f'_v \) with eigenvalue \( r(f'_v) > 0 \), then \( \psi(u) > 0 \).

(A4) There exist \( \delta > 0 \) such that \( \delta \leq 1 \) and \( t f(v) \leq f(tv) \) for all \( 1 - \delta \leq t \leq 1 \). Then, the eigenvector of \( f \) in \( G \cap \Sigma \) is unique: \( \exists \lambda > 0, f(w) = \lambda w, w \in G \cap \Sigma \Rightarrow w = v \).

**Proof.** We only need to verify that \( f \) satisfies assumptions (A1)-(A5) of Corollary 9.1. Assumption (A1) of Corollary 9.3 corresponds to (A1) of Corollary 9.1. Assumption (A2) of Corollary 9.3 implies that \( f'_v(C) \subset C \), by definition of the WKR condition, that is, assumption (A4) of Corollary 9.1. By Lemma 4.2 (vi), we get that assumption (A4) of Corollary 9.3 implies assumption (A5) of Corollary 9.1, since \( f'_v \) is linear. It remains to show assumptions (A2) and (A3) of Corollary 9.1. From assumptions (A4) and (A5) of Corollary 9.1, \( f'_v \) is homogeneous, order preserving and satisfies \( cw_C(f'_v) \leq 1 \), with \( cw_C(f'_v) \) as in (5.2). From Lemma 5.1 it follows that \( \tilde{r}_C(f'_v) \leq 1 \), and since \( f'_v \) is linear, we get that \( r(f'_v) \leq 1 \). Consider first the case where \( r(f'_v) < 1 \). Then, by Proposition 5.1, \( \text{Id} - f'_v \) has Property (F), or is a semi-Fredholm operator with index in \( \mathbb{Z} \cup \{-\infty\} \), which shows assumption (A2) of Corollary 9.1 and \( N(\text{Id} - f'_v) = \{0\} \), which implies assumption (A3) of Corollary 9.1. Consider now the case where \( r(f'_v) = 1 \). Then, by assumption (A2) of Corollary 9.3, \( \text{Id} - f'_v \) is a semi-Fredholm operator, and since the dimension of \( N(\text{Id} - f'_v) \) is finite (equal to 1), the index of \( \text{Id} - f'_v \) is in \( \mathbb{Z} \cup \{-\infty\} \), hence assumption (A2) of Corollary 9.1 holds. Let \( x \) be a fixed point of \( f'_v \) in \( \psi^{-1}(0) \), that is, \( x \in N(\text{Id} - f'_v) \cap \psi^{-1}(0) \). By assumption (A3) of Corollary 9.3 we deduce that \( x = 0 \). This shows that assumption (A3) of Corollary 9.1 holds. \( \square \)

Corollary 9.3 partially extends [Nus88, Theorem 2.5]. We obtain the same conclusion with different assumptions: the condition WKR is replaced by the stronger KR condition; the map \( f \) is assumed to be \( C_1 \), whereas we only assume \( f \) to be
differentiable at \( v \); condition (A4) is assumed for all \( v \in \Sigma \cap G \), whereas we only require it for the fixed point \( v \); but we require the cone \( C \) to be normal, whereas the result of Nus88 is valid for a general proper cone \( C \).

10. Application to nonexpansive self-maps of AM-spaces with unit

In this section, we give additive versions of the results of Section 7 motivated by the case of Shapley operators of zero-sum games with a compact state space \( K \). The latter operators are order preserving and sup-norm nonexpansive maps acting on a Banach space \( \mathcal{E}(K) \).

Since for any Banach space \( (X, \| \cdot \|) \), the corresponding metric space \( (V, d) \) (with \( V = X \) and \( d(x, y) = \| x - y \| \)) satisfies assumptions (B1), (B2) and (B3), the following additive versions of Theorems 7.1 and 7.2 are obtained directly from Theorems 6.1 and 6.8 together with Remark 6.9.

**Corollary 10.1.** Let \( (X, \| \cdot \|) \) be an AM-space with unit, let \( G \) be an open subset of \( X \) and let \( F : G \to X \) be a nonexpansive map with respect to \( \| \cdot \| \). Let \( v \in G \) be a fixed point of \( F \): \( F(v) = v \). Make the following assumptions:

(A1) \( F \) is semidifferentiable at \( v \).
(A2) The map \( \text{Id} - F'_v : X \to X \) has Property (F).
(A3) The fixed point of \( F'_v : X \to X \) is unique: \( F'_v(x) = x, x \in X \Rightarrow x = 0 \).

Then, the fixed point of \( F \) in \( G \) is unique: \( F(w) = w, w \in G \Rightarrow w = v \).

**Corollary 10.2.** Let \( (X, \| \cdot \|) \) be an AM-space with unit, let \( G \) be an open subset of \( X \) and let \( F : G \to G \) be a nonexpansive map with respect to \( \| \cdot \| \). If \( F \) has a fixed point \( v \in G \) and if \( F \) is semidifferentiable at \( v \), with \( \tilde{r}(F'_v) < 1 \), the fixed point of \( F \) in \( G \) is unique. Moreover, if \( G \) is connected, we have:

\[
(10.1) \quad \forall x \in G, \limsup_{k \to \infty} \| F^k(x) - v \|^{1/k} \leq \tilde{r}(F'_v).
\]

Recall that when \( (X, \| \cdot \|) \) is an AM-space with unit, denoted by \( e \), we denote by \( \omega \) the seminorm \( \omega_e \) defined in (2.7). Applying Theorem 6.1 to the metric spaces \( (V, d) \) corresponding to the Banach spaces \( (\psi^{-1}(0), \| \cdot \|) \) and \( (\psi^{-1}(0), \omega) \) with \( \psi \in (X^+) \setminus \{0\} \), or replacing \( X \) by \( \psi^{-1}(0) \) and perhaps \( \| \cdot \| \) by \( \omega \) in Corollary 10.1, one would have obtained an additive version of Theorem 7.3. The following additive version of Theorem 7.5 will be derived from Corollary 10.1.

**Corollary 10.3.** Let \( (X, \| \cdot \|) \) be an AM-space with unit, denoted by \( e \), and let \( \psi \in (X^+) \setminus \{0\} \), and denote by \( \omega \) the seminorm \( \omega_e \) defined in (2.7). Let \( G \) be an open subset of \( X \) and let \( F : G \to X \) be a map such that \( F|_{G \cap \psi^{-1}(0)} \) is nonexpansive with respect to \( \omega \). Let \( v \in G \cap \psi^{-1}(0) \) be a fixed point of \( F \): \( F(v) = v \). Make the following assumptions:

(A1) \( F \) is semidifferentiable at \( v \).
(A2) The map \( (\text{Id} - F'_v)|_{\psi^{-1}(0)} : \psi^{-1}(0) \to X \) has Property (F).
(A3) The fixed point of \( F'_v \) in \( \psi^{-1}(0) \) is unique: \( F'_v(x) = x, x \in \psi^{-1}(0) \Rightarrow x = 0 \).
(A4) \( F'_v \) is order preserving.
(A5) \( F'_v \) is additively subhomogeneous.

Then, the additive eigenvector of \( F \) in \( G \cap \psi^{-1}(0) \) is unique: \( \exists \lambda \in \mathbb{R}, F(w) = \lambda e + w, w \in G \cap \psi^{-1}(0) \Rightarrow w = v \).
Proof. Since the assumptions and conclusions of the corollary depend only on \( \psi^{-1}(0) \), we may assume that \( \psi(e) = 1 \). Let \( \tilde{F} : G \to \psi^{-1}(0), x \mapsto F(x) - \psi(F(x))e \) and denote \( H = \tilde{F}|_{G \cap \psi^{-1}(0)} \). We shall prove that \( H \) satisfies the assumptions of Corollary 10.1 for the Banach space \((\psi^{-1}(0), \omega)\). Since \( F|_{G \cap \psi^{-1}(0)} \) is nonexpansive with respect to \( \omega \), and \( \omega(x + ae) = \omega(x) \) for all \( x \in G \), \( H \) is nonexpansive with respect to \( \omega \). Since \( F(v) = v \) and \( v \in G \cap \psi^{-1}(0) \), \( H(v) = v \). Since \( F \) is semidifferentiable at \( v \) and the map \( R : X \to \psi^{-1}(0), x \mapsto x - \psi(x)e \) is linear, thus differentiable at any point, \( \tilde{F} = R \circ F \) is semidifferentiable at \( v \), by Lemma 3.3 and \( \tilde{F}' = R \circ F' \). This implies that \( H \) is semidifferentiable at \( v \) with \( H'_v = \tilde{F}'|_{\psi^{-1}(0)} : \psi^{-1}(0) \to \psi^{-1}(0) \). We thus get assumption (A1) of Corollary 10.1. Taking \( C = X^+ \), and using assumptions (A4) and (A5) of Corollary 10.3, we obtain by the same arguments as in the proof of Theorem 7.5, the following inequality:

\[(10.2) \quad \|x - F'_v(x)\| \leq 2\|x - H'_v(x)\| \quad \forall x \in \psi^{-1}(0).\]

Then, using \( H'_v(x) = F'_v(x) - \psi(F'_v(x))e \) and (10.2), we obtain, by the same arguments as in the proof of Theorem 7.5, assumptions (A2) and (A3) of Corollary 10.1 with \( X \) replaced by \( \psi^{-1}(0) \). If \( w \in G \cap \psi^{-1}(0) \) satisfies \( F(w) = \lambda e + w \) for some \( \lambda \in \mathbb{R} \), we get \( H(w) = w \), and by Corollary 10.1 we obtain \( w = v \). \( \square \)

Remark 10.4. As for Theorem 7.5, Corollary 10.3 can be applied in the following situations. From Lemma 4.7, assumption (A4) of Corollary 10.3 is fulfilled as soon as \( F \) is order preserving in a neighborhood of \( v \), and assumption (A5) is fulfilled as soon as \( F \) is additively subhomogeneous in a neighborhood of \( v \). Moreover, these properties imply, by Lemma 4.6, that \( F|_{G \cap \psi^{-1}(0)} \) is nonexpansive with respect to \( \omega \).

The following additive version of Corollary 7.4 will be derived from Corollary 10.3.

Corollary 10.5. Let \((X, \| \cdot \|)\) be an AM-space with unit, denoted by \( e \), and let \( F : X \to X \) be an additively homogeneous and order preserving map. Let \( S = \{ x \in X \mid F(x) = x \} \), and assume that \( v \in S \). Make the following assumptions:

(A1) \( F \) is semidifferentiable at \( v \).

(A2) The map \( \text{Id} - F'_v : X \to X \) has Property (F).

(A3) If \( F'_v(x) = x \) for some \( x \in X \), then \( x \in \{ \lambda e \mid \lambda \in \mathbb{R} \} \).

Then, \( S = \{ v + \lambda e \mid \lambda \in \mathbb{R} \} \).

Proof. Let us check that \( F \) satisfies the assumptions of Corollary 10.3. Consider \( G = X, \psi \in (X^+)^* \setminus \{0\} \) such that \( \psi(e) = 1 \). Since \( F \) is additively homogeneous and \( v + \lambda e \in S \) for all \( \lambda \in \mathbb{R} \). Moreover, since \( F \) is semidifferentiable at \( v \), \( F \) is semidifferentiable at \( v + \lambda e \) for all \( \lambda \in \mathbb{R} \), with \( F'_{v+\lambda e} = F'_v \). Taking \( \lambda = -\psi(v) \), we get \( \psi(v + \lambda e) = 0 \), and \( v + \lambda e \) satisfies all the assumptions of the corollary. Hence, replacing \( v \) by \( v + \lambda e \), we may assume that \( \psi(v) = 0 \).

We have \( v \in G \cap \psi^{-1}(0) \) and \( F(v) = v \). Since \( F \) is order preserving and additively homogeneous, \( F|_{\psi^{-1}(0)} \) is nonexpansive with respect to \( \omega \) (see Lemma 4.6). Assumptions (A1) and (A2) of Corollary 10.3 are implied by assumptions (A1) and (A2) of Corollary 10.5. Assumptions (A4) and (A5) of Corollary 10.3 are deduced from Lemma 4.7(ii) and (iii) using the fact that \( F \) is order preserving and additively homogeneous. This completes the proof of the assumptions of Corollary 10.3.
Let $x \in S$, and denote $\lambda = \psi(x)$. Since $F$ is additively homogeneous, $y = x - \lambda e$ satisfies $F(y) = y$ and $y \in \psi^{-1}(0)$. From Corollary 10.3, this implies $y = v$, and hence $x = \lambda e + v$. Since we already proved above the converse implication, this yields the conclusion of the corollary. 

The following is the additive version of Theorem 7.8.

**Corollary 10.6.** Let $(X, \| \cdot \|)$ be an AM-space with unit, denoted by $e$, and denote by $\omega$ the seminorm $\omega_e$ defined in (2.7). Let $F : X \to X$ be an additively homogeneous and order preserving map, denote $S = \{ x \in X \mid F(x) = x \}$, and assume that $v \in S$. Make the following assumptions:

(A1) $F$ is semidifferentiable at $v$;

(A2) $\tilde{r}(F'_v) < 1$, where $\tilde{r}$ is defined with respect to the seminorm $\omega$, as in (7.7), (7.8) (with $C = X$).

Then, for all $x \in X$,

$$\limsup_{k \to \infty} \omega(F^k(x) - v)^{1/k} \leq \tilde{r}(F'_v),$$

and there is a scalar $\lambda$ (depending on $x$), such that

$$\limsup_{k \to \infty} \| F^k(x) - \lambda e - v \|^{1/k} \leq \tilde{r}(F'_v).$$

**Proof.** We define $H$ and $\psi$ as in the proof of Corollary 10.3 so that $H$ leaves invariant the Banach space $\psi^{-1}(0)$ equipped with the norm $\omega$. Moreover, since $F$ is additively homogeneous, we get that $H^k(x) = F^k(x) - \psi(F^k(x))e$ for all $x \in X$ and $k \geq 1$. Then, Corollary 10.2 implies that

$$\limsup_{k \to \infty} \omega(F^k(x) - v)^{1/k} = \limsup_{k \to \infty} \omega(H^k(x) - v)^{1/k} \leq \tilde{r}(H'_v) = \tilde{r}(F'_v),$$

(recall that $\omega(x + ae) = \omega(x)$ for all $x \in X$ and $a \in \mathbb{R}$), which shows (10.3). Now, we use the additive analogue of the 1-cocycle formula (7.16), namely

$$F^k(x) = \left( \psi(F \circ H^{k-1}(x)) + \cdots + \psi(F \circ H^0(x)) \right) e + H^k(x),$$

and by a straightforward adaptation of the argument of the second part of the proof of Theorem 7.8 we conclude that (10.4) holds for some scalar $\lambda \in \mathbb{R}$. 

**Remark 10.7.** One may have derived Corollary 10.5 from Corollary 7.7 by using the Kakutani-Krein theorem and exp-log transformations as follows (see Section 2.3). Let $\iota : X \to \mathcal{C}(K)$ (where $K$ is a compact set), $C = \mathcal{C}^+(K)$, int $C$ and log : int $C \to \mathcal{C}(K)$ be defined as in Section 2.3. Denote $j = \iota^{-1} \circ \log : \text{int } C \to X$. Then, $j^{-1} = \exp \iota$, where $\exp = \log^{-1}$. To a map $F : X \to X$, one associates the map $f : \text{int } C \to \text{int } C$, $f = j^{-1} \circ F \circ j$. Any additive property (homogeneity, subhomogeneity, order preserving property) of $F$ is transformed into its multiplicative version for $f$. Moreover, since $\iota$ is an isometry, $F$ is Lipschitz continuous for the norm of $X$ if, and only if, $f$ is Lipschitz continuous for the Thompson metric of $C$, and this implies that $f$ is locally Lipschitz continuous for the sup-norm of $\mathcal{C}(K)$. Hence, the differentiability of the exp, log, $\iota$ and $\iota^{-1}$ transformations implies, from Lemma 3.3, that, when $F$ is Lipschitz continuous, the semidifferentiability of $f$ is equivalent to that of $F$. This allows us to derive Corollary 10.5 from Corollary 7.7, since in this case $F$ is nonexpansive (by Lemma 4.6), hence Lipschitz continuous with respect to $\| \cdot \|$. However, in order to derive Corollary 10.3 from Theorem 7.5 and Corollary 10.6 from Theorem 7.8, one should have first generalized Theorem 7.5.
and Theorem 7.8 to the case where $\psi$ is a nonlinear order preserving homogeneous map from int $C$ to $\mathbb{R}^+$ (the linearity of $\psi$ is not preserved by taking “log-glasses”).

11. AN EXAMPLE OF THE STOCHASTIC GAME

As a simple illustration of the present results, consider the following zero-sum two player game, which may be thought of as a variant (with additive rewards) of the Richman games \cite{LLP99} or of the stochastic tug-of-war games \cite{PSSW09} arising in the discretization of the infinity Laplacian \cite{Obe05}.

Let $G = (V, E)$ denote a (finite) directed graph with a set of nodes $V$ and a set of arcs $E \subseteq V \times V$. Loops, i.e., arcs of the form $(i, i)$, are allowed. We assume that every node has at least one successor (for every $i \in V$, there is at least one $j \in V$ such that $(i, j) \in E$). We associate to every arc $(i, j) \in E$ a payment $A_{ij} \in \mathbb{R}$. Two players, called “Max” and “Min”, will move a token on this digraph, tossing an unbiased coin at each turn, to decide who plays the turn. The player (Max or Min) who just won the right to play the turn must choose a successor node $j$ (so that $(i, j) \in E$) and move the token to this node. Then, Player Max receives the payment $A_{ij}$ from Player Min. We denote by $v_i(k)$ the value of this game in $k$ turns, provided the initial state is $i \in V$. We refer the reader to \cite{MS96,FV97,NS03} for background on zero-sum games, including the definition and properties of the value. In particular, standard dynamic programming arguments show that the value of the game in $k$ turns does exist, and that the value vector $v(k) := (v_i(k)) \in \mathbb{R}^V$ satisfies

$$v(k) = F(v(k-1)), \quad v(0) = 0,$$

where $F$ (the Shapley operator) is the map $\mathbb{R}^V \to \mathbb{R}^V$ given by

$$F_i(x) = \frac{1}{2} \left( \max_{j \in V} (A_{ij} + x_j) + \min_{j \in V} (A_{ij} + x_j) \right), \quad \forall i \in V.$$ 

The map $F$ is additively homogeneous and order preserving. We are interested in the mean payoff vector

$$\chi_i(F) := \lim_{k \to \infty} v_i(k)/k = \lim_{k \to \infty} F^k(0)/k;$$

hence, $\chi_i(F)$ represents the mean payoff per time unit starting from the initial state $i$, when the number of turns $k$ tends to infinity. We shall consider, for simplicity, the case in which $F$ has an additive eigenvector $u \in \mathbb{R}^n$ with associated eigenvalue $\mu \in \mathbb{R}$, meaning that $F(u) = u + \mu e$ where $e$ denotes the unit vector of $\mathbb{R}^n$. Then,

$$\chi_i(F) = \mu e.$$

Actually, the generalized Perron-Frobenius theorem in \cite{GC04} implies that the additive eigenpair $(u, \mu)$ does exist if the graph of the game $G$ is strongly connected.

The vector $u$, which is sometimes called bias, or potential in the dynamic programming literature, can be interpreted as an invariant terminal payoff. Indeed, consider the auxiliary game in which all the rewards $A_{ij}$ are replaced by $A_{ij} - \mu$, and a terminal payment $u_i$ is paid by Min to Max if the terminal state is $i$. Then, the equation $F(u) = \mu e + u$, or $-\mu e + F(u) = u$ means that the value of this modified game is independent of the number of turns (the operator $x \mapsto -\mu e + F(x)$ being interpreted as the dynamic programming operator of this modified game). An interesting feature of a bias vector is that it determines stationary optimal strategies for both players, by selecting the actions attaining the maximum and minimum in the expression of $F(u)$.

The map $F$ is semidifferentiable. To see this, let $E^+_i(x)$ and $E^-_i(x)$ denote the set of nodes $j$ attaining the maximum and the minimum in (11.1). An application of Theorem 3.8 with Remark 3.14 shows that the semidifferential of $F$ at point $u$ does exist and is given by

$$(F'_u(x))_i := \frac{1}{2} \left( \max_{j \in E^+_i(u)} x_j + \min_{j \in E^-_i(u)} x_j \right).$$

Consider now as an example the digraph of Figure 1. The corresponding Shapley operator is given by

$$F(x) = \begin{pmatrix}
\frac{1}{2} \left( \max(x_1, 3 + x_2, -7 + x_3) + \min(x_1, 3 + x_2, -7 + x_3) \right) \\
\frac{1}{2} \left( \max(x_1, 3 + x_2, x_3) + \min(x_1, 3 + x_2, x_3) \right) \\
\frac{1}{2} \left( \max(x_1, 2 + x_2 + \min(3 + x_1, 2 + x_2) \right)
\end{pmatrix}.$$

The vector $u = (5, 0, 4)$ can be checked to be an additive eigenvector of $F$, with additive eigenvalue $\mu = 1$, i.e., $F(u) = \mu e + u$, so that the mean payoff per time unit is equal to 1 for all initial states (Max is winning 1 per time unit). We get

$$F'_u(x) = \begin{pmatrix}
\frac{1}{2} (x_1 + \min(x_2, x_3)) \\
\frac{1}{2} (x_1 + x_3) \\
\frac{1}{2} (x_1 + x_2)
\end{pmatrix}.$$

Let $t(x) := \max_{1 \leq i \leq n} x_i$, $b(x) := \min_{1 \leq i \leq n} x_i$, and $\omega(x) := \omega_e(x) = t(x) - b(x)$. One readily checks that

$$\omega(F'_u(x)) = \frac{1}{2} (x_1 + \max(x_2, x_3)) - \frac{1}{2} (x_1 + \min(x_2, x_3)) \leq \frac{1}{2} \omega(x).$$

Hence, $F'_u$ is a contraction of rate $1/2$ in the seminorm $\omega$, which implies that $r(F'_u) \leq 1/2$. In particular, every fixed point $x$ of $F'_u$ satisfies $x_1 = x_2 = x_3$. Hence, Corollary 10.5 shows that the set of additive eigenvectors of $F$ is precisely $S = \{u + \lambda e \mid \lambda \in \mathbb{R}\}$ (in other words, the bias vector is unique up to an additive constant). Moreover, Corollary 10.6 implies that for all $x \in \mathbb{R}^3$,

$$\limsup_{k \to \infty} \omega(F^k(x) - u)^{1/k} \leq 1/2,$$

and that there is a constant $\lambda \in \mathbb{R}$, depending on $x$, such that

$$\limsup_{k \to \infty} \|F^k(x) - \lambda e - u\|^{1/k} \leq 1/2.$$
