then, as Hurwitz showed,

$$(10) \quad \beta_{4m} = (1+i)^{4m} \{ (1+i)^{4m} - 2 \} E_m.$$

The writer [1, Theorem 9] has proved that if $p^r \mid m$, $p-1 \nmid 4m$, then

$$\beta_{4m} \equiv 0 \pmod{p^r}.$$

Thus (10) yields

$$(11) \quad \{ (1+i)^{4m} - 2 \} E_m \equiv 0 \pmod{p^r}.$$

Since $p-1 \nmid 4m$, the denominator of E_m is not divisible by p , so that (11) implies

$$(12) \quad \{ (1+i)^{4m} - 2 \} N_m \equiv 0 \pmod{p^r}.$$

In the next place, since

$$(1+i)^{4m} = (-4)^m,$$

it is evident that

$$(1+i)^{2m} - 2 \equiv 0 \pmod{p}$$

if and only if

$$(13) \quad (-1)^m 2^{2m-1} \equiv 1 \pmod{p}.$$

If, therefore, (13) is not satisfied, it is clear from (12) that

$$N_m \equiv 0 \pmod{p^r}.$$

Finally we note that if $p = m$, then (13) is not satisfied and (7) follows at once.

All Factors $q < 10^8$ in All Mersenne Numbers $2^p - 1$, p Prime $< 10^4$

By H. Riesel

During the year 1960 the author made additional investigations respecting factors of Mersenne numbers $M_p = 2^p - 1$, where p is a prime. The author has earlier examined the least factor q of M_p , for $p < 10^4$, if $q < 10 \cdot 2^{20} \approx 10^7$. This inquiry was secondary to an effort to ascertain Mersenne primes [1].

The present examination, which resulted in 255 new factors of the numbers M_p , was done in the following manner: All primes $s < 10^8$, for which $s \equiv 1 \pmod{2p}$ and $s \equiv 1 \pm 1 \pmod{8}$ were tested as factors of M_p for $1200 < p < 10000$. The range $p < 1200$ has been examined by Brillhart and Johnson [2].

Received February 10, 1961.

To save computing time the following scheme was used. If it takes long to decide whether a number s of the kind in question is a prime, but an examination of whether $2^p \equiv 1 \pmod{s}$ can be accomplished in a short time, it may be convenient to test unnecessarily some s -values which are not primes. Such values can be obtained by using such s -values as do not contain any factor $\leq t$, where t is given. If $\sqrt{s} \leq t < s$ only primes remain. Generally, if $t < \sqrt{s}$ the fraction

$$\gamma = \gamma(t) = \prod_{p=s}^t \left(1 - \frac{1}{p}\right), \quad p \text{ prime}$$

of all numbers remaining after this test. Preparing the program for use on the BESK, it was found by test runs that the computing time was minimal with the following t -values:

$t = 40$	for	$1200 < p < 2000$
$t = 70$	for	$2000 < p < 3000$
$t = 90$	for	$3000 < p < 4000$
$t = 120$	for	$4000 < p < 5000$
$t = 130$	for	$5000 < p < 6000$
$t = 170$	for	$6000 < p < 7000$
$t = 200$	for	$7000 < p < 10000$

The running time on the BESK was about 20 minutes for each p .

All Mersenne numbers M_p with $p < 10000$ have now been examined with respect to all factors $q < G = 10^8$; for some M_p this limit G has been considerably raised. A summary is given below of what in the author's opinion has so far been accomplished in this field:

$p \leq 97$	completely factored
$p = 101$	$G = 2^{35}$
$103 \leq p \leq 149$	$G = 2^{31}$
$p = 151$	completely factored
$157 \leq p \leq 257$	$G = 2^{31}$
$263 \leq p \leq 389$	$G = 2^{30}$
$p = 397$	$G = 2^{32}$
$401 \leq p \leq 1021$	$G = 2^{30}$
$1031 \leq p \leq 1193$	$G = 2^{28}$
$1201 \leq p \leq 2999$	$G = 10^8$
$3001 \leq p \leq 3593$	$G = 10^8$, if any factor is known
$3001 \leq p \leq 3593$	$G = 38400p + 1$, if no factor is known
$3607 \leq p \leq 9973$	$G = 10^8$

All hitherto known factors are to be found in [1], [2] and this paper. Furthermore, the author has calculated the two largest factors of M_{97} and M_{151} ; these are

$$13842607235828485645766393 \text{ and } 7289088383388253664437433$$

respectively.

As has earlier been pointed out [3], two typographical errors occurred in [1]; the factors belonging to M_{2689} and M_{5743} should be 7158119 and 643217, respectively.

Some of the factors referred to below have been calculated by Edgar Karst [4],

[5], namely, the 24 factors designated by an asterisk(*). Furthermore, all factors stated in [1] and [2] as well as in this paper have been checked with a special program and have been found correct, except for the typographical errors mentioned above.

Lastly, the author desires to express his gratitude to the Swedish Board for Computing Machinery, which has graciously provided machine time on the BESK for this study.

EDITOR'S NOTE: During the period in which this paper was in process of publication A. Hurwitz [6] has listed 92 Mersenne composites, corresponding to primes p in the interval $330 < p < 5000$, for which no factor is known at present. He also lists M_{8191} as such a composite number, and he announces the primality of M_{4253} and M_{4423} . S. Kravitz [7] has extended the writer's earlier table [1] to the range $10,000 < p < 15,000$.

Certain Properties of Pyramidal and Figurate Numbers

By M. Wunderlich

It is well known that despite some extensive computation [1], the only two known solutions to the Diophantine equation

$$(1) \quad a^3 + b^3 + c^3 = 3$$

are $a = b = c = 1$, and $a = b = 4, c = -5$. Professor Aubrey Kempner noted at a number theory seminar at the University of Colorado that these solutions also satisfy the equation

$$(2) \quad a^3 + b^3 + c^3 = a + b + c.$$

Therefore, it is of interest whether or not (2) has solutions other than these two and if so, how many. Since there are so few solutions known to (1), it seemed reasonable to conjecture that there would be only finitely many solutions to (2).

If we change the sign of the third variable and divide through by six, we see that (2) is equivalent to

$$\frac{a^3 - a}{6} + \frac{b^3 - b}{6} = \frac{c^3 - c}{6}$$

or

$$\frac{(a-1)(a)(a+1)}{6} + \frac{(b-1)(b)(b+1)}{6} = \frac{(c-1)(c)(c+1)}{6}.$$
