

## REVIEWS AND DESCRIPTIONS OF TABLES AND BOOKS

The numbers in brackets are assigned according to the indexing system printed in Volume 22, Number 101, January 1968, page 212.

- 49 [2, 3, 4].—JOSEF STOER, *Einführung in die Numerische Mathematik*. I; J. STOER & R. BULIRSCH, *Einführung in die Numerische Mathematik*. II, Springer-Verlag, New York, 1972; I: ix + 250 pp., 21 cm. Price \$4.70, II: ix + 286 pp., 21 cm. Price \$5.50.

Here is a modern introductory textbook for German-speaking people by leading German numerical analysts. Volume I covers interpolation, quadrature, linear equations, least squares, and the zeros of functions. An example of the scope of the work is the coverage of both the Cooley-Tukey algorithm and splines in the chapter on interpolation.

Volume II (written with R. Bulirsch) covers eigenvalues, ordinary differential equations, and the iterative solution of large systems of linear equations. An example treated at some length in Volume II is a realistic re-entry problem for a space vehicle.

Of all the English textbooks, one is reminded most of Isaacson and Keller's "Analysis of Numerical Methods".

There are problems at the end of each chapter and the book is in paperback.

B. P.

- 50 [2.05, 2.35].—A. MEIR & A. SHARMA, Editors, *Spline Functions and Approximation Theory*, Birkhäuser Verlag, Basel, Switzerland, 1973, 386 pp., 25 cm. Price Fr. 64.—.

This book is the proceedings of a symposium held at the University of Alberta in May, 1972. There are 15 papers and 4 abstracts and, as the title suggests, there is considerable emphasis on spline functions (seven papers). Some of the papers present original results and others survey various areas. Almost all of the papers are well done and some are excellent. The topics are so diverse that generalities do not apply; we present the author, title, length (in typewritten pages), and a very short summary for each of the 15 papers. The reviewer hopes the authors will forgive him if he has been unable to exhibit the entire content of their papers in two sentences or less.

BERENS, H., *Pointwise Saturation* (20 pages). This is a survey and reformulation of a wide variety of saturation results. The unifying theme in the presentation is the use of relationships with differential properties.

DAVIS, C., *A Combinatorial Problem in Best Uniform Approximation* (26 pages).

For a function  $f(x)$  which oscillates  $N$  times, we wish to determine the best approximation among those functions which oscillate  $m < N$  times. Various results are given including some leading to computational algorithms.

- DE BOOR, C., *Good Approximation by Splines with Variable Knots* (16 pages). This is a survey of various results and approaches to obtaining good (as opposed to best) knots for spline approximation. Emphasis is placed on obtaining knots efficiently which are valid for broad classes of functions.
- DE VORE, R. & RICHARDS, F., *Saturation and Inverse Theorems for Spline Approximation* (10 pages). A simpler proof is given of the saturation theorem for spline approximation where the knots satisfy a "mixing" condition. That this condition forces "bad" choices of knots in many situations can be seen by comparing the results with the convergence results of the preceding paper.
- DITZIAN, F. & MAY, C., *Saturation Classes for Exponential Formulae of Semi-Groups of Operators* (18 pages). The optimal rate of convergence (and corresponding saturation class) is obtained for approximation by the "exponential formulae". The context is  $C_0$  semi-groups of operators  $T(t)$ , and the analysis involves the infinitesimal generator.
- FIELDS, J. & ISMAIL, M., *On Some Conjectures of Askey Concerning Completely Monotonic Functions* (12 pages). Askey analyzed the  $L^p$  convergence of Lagrange interpolation at the zeros of  $P_n^{(\alpha, \beta)}(z)$  and made some conjectures concerning the positivity of certain Cesàro means. The authors have established five of these conjectures and give proofs for three of them here.
- GAUTHIER, P., *Une Application de la Théorie de l'Approximation à l'Etude des Fonctions Holomorphes* (6 pages). A very short proof by approximation theoretic methods is given for two recent results on meromorphic and holomorphic functions.
- JEROME, J., *Linearization in Certain Nonconvex Minimization Problems and Generalized Spline Projections* (50 pages). This long paper presents a variety of extensions of Jerome's earlier work on nonconvex minimization. Particular consideration is given to the minimization of a general bilinear form (not necessarily nonnegative) on a Sobolev space.
- LYCHE, T. & SCHUMACHER, L., *On the Convergence of Cubic Interpolating Splines* (22 pages). Conditions are established on a partition of an interval, so that natural cubic spline interpolation converges for all continuous functions. These are analogous to conditions of Marsden, Meir, Sharma and others for periodic splines.
- MOTZKIN, T., SHARMA, A. & STRAUS, E., *Averaging Interpolation* (44 pages). Polynomial interpolation with respect to certain linear functionals (averaging interpolation) is studied along with the related concept of relative unsolvence. Many results are established involving existence, uniqueness and representation.
- MUNTEANU, M., *On the Construction of Multidimensional Splines* (32 pages). A survey is given of methods to construct classes of splines which are combined interpolation and smoothing.
- OSTROWSKI, A., *On Error Estimates A Posteriori in Iterative Procedures* (10 pages). A survey is given of various approaches to obtain a posteriori error estimates for iterative computations.

- SCHOENBERG, I., *Splines and Histograms* (52 pages). Histosplines are splines which "interpolate" histograms in the sense of preserving area. A variety of theorems and constructions are given for univariate and bivariate histosplines.
- DE BOOR, C., *Appendix to "Splines and Histograms" by I. J. Schoenberg* (30 pages). This appendix presents and analyzes the tensor product nature of bivariate histosplines and develops algebraic machinery for their efficient calculation.
- STRAUS, E., *Real Analytic Functions as Ratios of Absolutely Monotonic Functions* (12 pages). A discussion is given of various results on the problem of determining under what conditions analytic functions, positive on a real segment, can be expressed as the ratio of two absolutely monotonic functions.

JOHN R. RICE

Purdue University  
Division of Mathematical Sciences  
Lafayette, Indiana 47907

- 51 [2.05, 2.35, 3.25].—F. A. LOOTSMA, Editor, *Numerical Methods for Non-Linear Optimization*, Conference sponsored by Science Research Council, University of Dundee, Scotland, 1971, Academic Press, New York, 1972, xiv + 439 pp., 24 cm. Price \$25.—.

This book is a collection of 29 papers presented at the Conference on Non-Linear Optimization held in Dundee, Scotland, in the summer of 1971. Within this general area the range of topics is rather broad. Ten papers treat general unconstrained optimization problems, with the total divided about equally between papers on theoretical results and those reporting experimental investigations; especially noteworthy in the former class is Dixon's paper on the equivalence of a large set of variable metric methods when exact line searches are performed. Three additional papers treat the special problem of non-linear least squares.

Three papers attack the difficult and important problem of finding or identifying global minima rather than merely local ones; McCormick's survey paper, in particular, can serve as a good introduction to this relatively unexplored area.

The remaining thirteen papers treat a variety of topics in constrained optimization, mainly from theoretical viewpoints; papers are included on quadratic programming, linearly-constrained programming, complementarity problems and especially on penalty-function methods. The general reader may find particularly informative the survey by Fletcher on linearly-constrained programming and that by Lootsma on solving constrained problems by means of solutions to unconstrained problems.

The majority of papers in this collection are specialized in the sense that they are probably of primary interest to the expert or practitioner in the field rather than to the general reader or novice who would like to get a general introduction to the area;

most specialists but few nonspecialists will want to own this book. A few of the papers, however, could be quite informative for the general reader; the above-mentioned papers of Lootsma, Fletcher, and McCormick are in this class, as are, to a somewhat lesser extent, the reports of computational experiments by Himmelblau and by Sargent and Sebastian.

J. W. D.

52 [4, 5].—GUNTER H. MEYER, *Initial Value Methods for Boundary Value Problems*, Academic Press, New York, 1973, x + 220 pp., 24 cm. Price \$14.50.

MELVIN R. SCOTT, *Invariant Imbedding and its Applications to Ordinary Differential Equations. An Introduction*, Addison-Wesley, Reading, Mass., 1973, 215 pp. Price \$19.50, cloth, \$11.50, paperbound.

Although these books deal with the same topic, there is remarkably little overlap. When they are to be distinguished in this review, the author's initials will be used. The books are monographs devoted to the technique of invariant imbedding as applied mainly to two point boundary value problems for ordinary differential equations. There are several ways of viewing invariant imbedding. The original view is to consider a particular problem as imbedded in a family of problems with the length of the interval as a parameter. The invariant imbedding equations are differential equations for the unknown boundary values as a function of this parameter. These equations turn out to have specified initial values, in this respect, they are simpler than the original problem. Moreover, the approach is a natural one to some problems, e.g. when only the missing boundary values are of interest, or for parameter studies varying the interval length, or when a free boundary is to be located. Another view of invariant imbedding is as a kind of shooting method. A third view appropriate to linear problems is based on Riccati equations and is a natural approach to Sturm-Liouville problems.

When the ordinary differential equation is nonlinear, the imbedding equations are partial differential equations. They are the principal object of the theory in GHM and are thoroughly investigated using characteristic theory. Numerical aspects of the solution of the partial differential equations are treated as well. MRS is almost wholly concerned with linear problems, which lead to initial value problems for ordinary differential equations. His analysis is based on the Riccati approach and particular attention is given to the computation of the solution (as opposed to the missing boundary values). GHM is the more demanding of mathematical background, but both books place modest demands on the reader. Both books are clearly written and well structured, though both would have profited by more careful proof reading.

It is frequently the case that the invariant imbedding equations are stable and represent an effective way to solve boundary value problems. The authors do not attempt to evaluate the approach in comparison to alternatives, though MRS explicitly

responds to criticisms of the approach. There can be difficulties such as instability, stiffness, cancellation, and critical lengths. Some of these are brought out by example, though the reviewer's experience has been that stiffness is a common and serious difficulty which neither author mentions. There are some nice applications of physical interest which are detailed in examples. The Stefan problems and oil reservoir problem in GHM and the Sturm-Liouville problems in MRS particularly appeal to the reviewer.

It will dishearten those writing codes for initial value problems to learn that nearly all the examples in both books were computed using fixed-step, fourth-order Runge-Kutta codes. The techniques being studied are utterly dependent upon the reliable, efficient solution of initial value problems. Because they were obtained from long obsolete codes, the computations reported cannot be used to assess the reliability and effectiveness of the approach nor its efficiency as compared to methods not based on initial value problems. Since this situation is all too common, the reviewer points out there have been three substantial evaluations of codes for the initial value problem published in recent years. There is a high quality, portable code in the text of C. W. Gear (published 1971, reviewed *Math. Comp.*, v. 27, 1973, p. 673) and there are several other codes as good or better which can be easily obtained. With the ready availability of these codes, workers requiring the solution of an initial value problem no longer have any excuse for using codes of lesser quality.

L. F. SHAMPINE

Sandia Laboratories

53 [5, 13.20].—PATRICK J. ROACHE, *Computational Fluid Dynamics*, Hermosa Publishers, Albuquerque, New Mexico, 1973, vii + 434 pp., 27 cm. Price \$12.50.

Chapter headings: 1. Introduction. 2. Incompressible Flow Equation in Rectangular Coordinates. 3. Basic Computational Methods for Incompressible Flow. 4. Compressible Flow Equations in Rectangular Coordinates. 5. Basic Computational Tools for Compressible Flow. 6. Other Mesh Systems, Coordinate Systems, and Equation Systems. 7. Recommendations on Programming, Testing, and Information Processing.

This book is aimed at the person interested in the practical application of its subject. The methods included are described in enormous detail, with emphasis on recipes rather than principles. Practical hints abound, and some of them, in particular in Chapter 7, are quite good.

The book operates, however, within narrow limits. The methods included are simple, with one exception—low order, difference schemes. No substantive discussion is given of spectral methods, finite element or Galerkin methods, higher accuracy methods for compressible flow, or Monte Carlo methods. No proper discussion is given of the effect of boundary conditions on stability. The author suggests that the short-

comings of frozen-coefficient stability analysis can be ascribed to a defect in the definition of stability, and that there do not exist exact analyses of nonlinear problems.

He distinguishes between his field of Computational Fluid Dynamics, and a broader field, Numerical Fluid Dynamics, which is not included in the book, and which presumably contains high accuracy methods as well as the appropriate analysis.

Even the subjects included are treated in an inadequate and slipshod manner. A few examples: the author is enthusiastic about upstream (first order!) differencing, although he quotes, without comment, another author who called it unacceptable. He quotes, approvingly, results obtained with this method at a Reynolds number  $R = 10^6$ . As his own paper at the end of the book shows, the numerical diffusion in such a scheme is of the order of the mesh size; the contradiction is never resolved.

The discussion of boundary conditions for the pressure in the incompressible  $(V, p)$  equations is misleading. The author does indicate some of the disasters which may ensue from the application of his rules, and then merely gives a recipe for keeping the pressure bounded in a specific case, although the general theory is well known. He also states flatly and erroneously that there are no implicit  $(V, p)$  formulations available.

Higher order methods for the gas dynamics equations are dismissed because the solutions are not smooth; this would, of course, be a reason for advocating such methods, as an inspection of the Fourier-space characterization of accuracy would reveal. Richardson extrapolation is also dismissed, even for viscous flow.

In summary, this long book is not only inadequate, but also pernicious. It fosters the attitude that accuracy and analysis are the realm of effete "numerical" fluid dynamicists and not useful to practical people. If taken seriously, this book may delay the maturation of its subject.

54 [8].—CHARLES E. LAND, *Tables of Standard Confidence Limits for Linear Functions of the Normal Mean and Variance*, Department of Statistics, Atomic Bomb Casualty Commission, Hiroshima, Japan 730. Ms. of 6 pp. + 65 computer sheets (reduced) deposited in the UMT file.

The tabulated values of  $C(s; \nu, \alpha)$ ,  $C_{-1}(s; \nu, \alpha)$ , and  $C_{+1}(s; \nu, \alpha)$  represent scaled level  $\alpha$  confidence limits for  $\mu + \lambda\sigma^2$ , for arbitrary nonzero  $\lambda$ , where  $\mu$  and  $\sigma^2$  are, respectively, the unknown mean and variance of a normal distribution. These limits correspond to observed values of  $(Y, S)$ , where  $Y \sim N(\mu, \sigma^2/\gamma^2)$ ,  $\gamma$  is a known positive number, and  $S^2$  is distributed independently as  $\sigma^2/\nu$  times a chi-square variate with  $\nu$  degrees of freedom. For a given observed value  $(y, s)$ , the level  $\alpha$  one-

sided upper confidence limit for  $\mu + \lambda\sigma^2$  is  $y + \delta\beta s\{\nu^{-1/2}C(\beta s; \nu, \alpha^*) + \beta s/2\}$ , where  $\delta = (\nu + 1)/(2\lambda\gamma^2)$ ,  $\beta = 2|\lambda|\gamma/(\nu + 1)^{1/2}$ , and  $\alpha^* = \alpha$  or  $1 - \alpha$  according as  $\lambda$  is positive or negative. Similarly, the corresponding lower and upper two-sided limits are  $y + \delta\beta s\{\nu^{-1/2}C_{\mp \text{sgn}(\lambda)}(\beta s; \nu, \alpha) + \beta s/2\}$ .

One-sided standard limits  $C(s; \nu, \alpha)$  are given to 3D in Table 1 for  $s = 0.1(0.1)1(0.25)2(0.5)10$ ,  $\nu = 2(1)30(5)50(10)100(20)200(50)500(100)1000$ , and  $\alpha$  (and  $1 - \alpha$ ) = 0.0025, 0.005, 0.01, 0.025, 0.05, 0.1, 0.25, 0.5. Two-sided standard limits  $C_{\mp}(s; \nu, \alpha)$  are presented (also to 3D) in pairs in Table 2 for the same range of  $s$ , and for  $\nu = 2(2)20$ ,  $\alpha = 0.5, 0.8, 0.9, 0.95, 0.98, 0.99, 0.995$ . The author recommends quadratic or cubic interpolation on  $s$  and  $\nu$  to obtain intermediate values from these tables.

The present tabular entries were calculated with the aid of extensive tables of critical values [1] by the same author. Abridged versions of the tables under review, together with a discussion of their evolution and construction, have been published by the author [2].

55 [12].—DONALD E. KNUTH, *The Art of Computer Programming*, Vol. 3: *Sorting and Searching*, Addison-Wesley Publishing Co., Reading, Mass., 1973, xi + 722 pp. Price \$19.50.

One of the more important events to occur in the field of computers and information sciences has been the appearance of the first three volumes of *The Art of Computer Programming* by Donald E. Knuth. In all, a total of seven volumes are to be published, comprising twelve chapters. Volume 1 presents basic material in discrete mathematics, basic programming concepts via a hypothetical computer (MIX), and fundamental algorithms for the manipulation of data structures (see *Math. Comp.*, v. 23, 1969, pp. 447–450, RMT 18). Volume 2 is concerned with random number generation and with approximate and exact computer arithmetic and topics in computer algebra (see *Math. Comp.*, v. 24, 1970, pp. 479–482, RMT 26). Volume 3, the subject of this review, treats the fundamental algorithms for sorting and searching. Volume 4 will deal with combinatorial algorithms, Volume 5 with syntactic algorithms, Volume 6 with mathematical linguistics, and finally Volume 7 with compilers.

Prior to the appearance of the first volume, authorship of a series of books of such scope and magnitude by a single person was the object of reasonable skepticism.

The amount of material to cover is so immense and the degree of detail required for thorough treatment so great that one would expect rather a Bourbaki-like group as the author. The appearance of Volume 1 did a great deal to remove such skepticism and, with the publishing of Volume 2 and now Volume 3, there can no longer be any skeptics. The latest book, Volume 3, together with the first two volumes, represents a degree of scholarship that is unsurpassed in the field of computer science and, indeed, ranks among the very finest of scientific textbooks.

In the preface of Volume 1, Knuth set forth the theme of this set of books: nonnumerical analysis or the analysis of algorithms, which is to be interpreted as the "theory of the properties of particular computer algorithms." One thus finds for the class of algorithms treated in each volume the following essential ingredients:

- (1) algorithm descriptions in a clear semiformal step-by-step notation,
- (2) programs implementing many of the algorithms in the assembly language of the hypothetical (though representative) computer MIX,
- (3) space and computing time analyses of the algorithms and programs, occasionally supplemented by empirical simulation studies.

In addition, a standard feature of each book is a large selection of exercises, divided among the various sections which cover the above three general categories. The exercises range in degree of difficulty from the novice to the expert, some being unsolved research problems, and are ranked accordingly via the author's "logarithmic" scale. The answers, or sketches thereof, for most of the exercises are given in a separate section near the end of each volume and represents a major part of the attractiveness of the books. Also included are sections giving bibliographies and historical surveys of the subject areas, appendices listing important constants to high precision, definitions and references for notation.

Volume 3, entitled *Sorting and Searching*, fits this general description. It consists of two chapters: Chapter 5, which is devoted to sorting, and Chapter 6, which is concerned with searching. The methods of each of these topics fall into two classes depending on the size of the file involved. If the file (and the required auxiliary storage) fits in the computer's high-speed internal memory, internal sorting and internal searching methods apply; otherwise, relatively slow external memory devices (tapes, disks, drums) must be used and external sorting and external searching methods then apply. This is the basis for the main division of sorting methods in Chapter 5 into internal sorting and external sorting. However, Knuth first introduces the reader to the combinatorial properties of permutations, a topic essential to the analysis of sorting algorithms. This material requires a mathematically mature reader and may be skipped by one not intending to pursue the analysis of the algorithms. The important topics of inversions, permutations of multisets, runs, and tableaux and involutions are treated. One more major section is included in Chapter 5 on optimum sorting methods. This concerns the inherent complexity of sorting and is directed towards minimizing the comparison of

keys in sorting or merging files or selecting the  $k$ th largest item; the design of sorting networks is also included. Although most of this material may be omitted without detriment to an understanding of the algorithms, those who are mathematically inclined will find the mathematical analyses enjoyable.

The treatment of internal and external sorting are comprehensive and well organized. Knuth's organization of internal sorting methods, although admittedly "not always clearcut," is based on the "dominant characteristic" of a method and is as follows. The subject is introduced with enumeration methods: comparison counting and distribution counting. Next follow the insertion sort methods: straight and binary insertion, diminishing increments (Shell's method), list insertion, and address calculation (multiple list insertion). Following this are the exchange sort methods, exchange selection ("bubble sort"), merge exchange (Batcher's parallel sort), partition exchange (Hoare's quicksort), and radix exchange. The fourth group is characterized by repeated selection of items in increasing (or decreasing) order of key size: straight selection and its refinements, tree selection and its evolution to William's Heapsort (with improvements by Floyd). The next group is based on merging: straight two-way merge sort and list merge sort. The final category, sorting by distribution, is concerned with radix sorting, especially linked list techniques. The treatment of internal sorting is concluded with a useful summary and an analytical and empirical comparison of these methods.

The treatment of external sorting is no less well organized, presenting the subject as an "internal sorting" phase followed by an "external merging" phase. The method of replacement selection is presented as the most desirable in constructing the initial runs in the internal sorting phase. Several methods are then presented for doing the external merging phase for tapes, with the merge patterns being obtained for somewhat idealized situations. The methods treated are polyphase merge and cascade merge, variations of these when reading tape backward is possible, and a method which oscillates between distribution and merging. The physical properties of tapes and their influence on external sort algorithms (e.g., stop-start delay, rewinding, overlapping  $I/O$ , etc.) are discussed, along with the technique of forecasting. Also presented is a revealing illustration of the effectiveness of ten representative merge strategies applied to a file of 100,000 100-character records. Estimates of the run times, obtained from analytically derived formulae, are compared with the actual run times, a history of these runs being displayed on a remarkable foldout. After treating two specialized topics, external radix sorting and two-tape sorting, Knuth concludes the topic of external sorting with a discussion of disk and drum sorting.

Chapter 6 is concerned with searching, a subject related to sorting but not as well developed; this is reflected in its relatively shorter length, being only half as long as Chapter 5. Still most of the searching techniques that are known have been covered. Sequential search methods, being the most simple, are first described and the probability of access considered, including Zipf's law, the so-called "80-20" rule, etc. Quick and quicker sequential search algorithms are then given (the reviewers were disappointed that

these were not followed by a “quickest” search algorithm) and tape searching is considered. There then follow several groups of methods based on key comparisons. Searching ordered sequential tables is treated, including binary search and its improvements, and Fibonacci search. Binary tree search next follows with some treatment of optimum trees. Balanced binary trees (AVL trees) then follow with algorithms for insertion, deletion, concatenation and splitting being described. Also included in this topic is the representation of linear lists by balanced trees and alternatives to them. A topic in external searching is next presented, namely multiway trees (a generalization of binary trees) and a special case called *B*-trees. These are useful for organizing large files on disks and drums.

Digital searching methods, particularly useful for natural language dictionary look-ups, are developed. The Trie search of Fredkin, a method used in a system called PATRICIA, and a digital tree search are compared. The reviewers would have expected to see more description of Sussenguth’s work, which encompasses Trie search. The treatment of primary key searching is concluded with a long section on hashing. The best general techniques for computing hash functions, those based on simple multiplication and division, are treated in detail, although a number of standard techniques are ignored. Of course, methods of resolving collisions such as “open addressing” and “chaining” are described, along with numerous variations. However, the interesting method of random probing is relegated to an exercise. Methods based on hashing for external searching on direct-access devices are also described. The search methods based on hashing are then compared with each other and with other search methods.

The last section of the book treats retrieval on secondary keys, which arise in queries based on possibly several attributes or keys of the records. Several important techniques for secondary key retrieval are considered: inverted files, compound attributes, binary attributes, superimposed coding, combinatorial hashing, and balanced filing schemes. Owing to the recent development of many of these methods, not as much is known about secondary key retrieval. Consequently, the treatment of this challenging subject is rather brief and is not afforded the same thoroughness which characterizes the preceding sections. Still, the reviewers were delighted to see its inclusion.

Computer science has been looked upon by many as a collection of ad hoc tricks for its practitioners, where indeed the term “science” does not even belong. The work of Knuth and others is establishing the mathematical foundations associated with the many techniques, and is removing the “ad hockery” which has characterized the field. Based on this, one can quantitatively determine which techniques are superior in general or under certain conditions. Volume 3 is a good example of the success of Professor Knuth’s viewpoint on the importance of algorithm analysis in computer science.

To be sure, this book is not completely free of flaws, although in this case the flaws appear only in applying the measure of excellence which the author is helping to establish for this field. Regarding errata, the author maintains a complete list of

errors and intended changes (a one or two dollar prize for each new error found by a reader is offered) and makes this available to his readers (see Donald E. Knuth, *Sorting and Searching—Errata and Addenda*, Stanford University Computer Science Department Technical Report #STAN-CS-73-392 (Oct. 1973)). Although the number of corrections is quite large, they are mostly minor, consisting of notational changes, amended references to previous or current work, new, corrected, or reranked exercises and answers, and expansions and corrections to the text. These changes will be incorporated into later editions. Outright misprints are few. Knuth views *The Art of Computer Programming* as an ongoing project and consequently many of the corrections are intended merely to make a good thing better. Regarding the book as a whole, the weaknesses, if there are any, lie in the latter part of Chapter 6, as noted previously. The reviewers would not be surprised to see this portion expanded and subdivided in future editions as the subject develops.

The book is capable of being read at several levels of sophistication, can serve several purposes, and is pertinent to a variety of interests. It may be used for self-study, as a reference source, and as a textbook for a second course in data structures, for the analysis of algorithms, and for concrete complexity studies. The style of writing is interesting and engaging, and the treatment is often so engrossing that it is difficult to stop reading. Those who are interested in the historical aspects of the techniques will find many historical insights into events dating back to the days before the development of computers. The book is mostly self-sufficient, except for some references to material from Volume 1 in discrete mathematics, basic data structures (a little), and, of course, MIX programming. This illustrates a nice coordination of the separate volumes. Volume 3 shares with the preceding volumes the role of a stimulus for research and further development of the area (especially searching) and as somewhat of a forum for the establishment of historical fact, for the standardization of terminology, for the collection of results and problems (new and used). Incidentally, Volume 3, which is 722 pages long, dedicates 102 pages to exercises (73 on sorting and 29 on searching) and contains a 130-page section of answers to the exercises.

The major strength of this book lies not with the amassing of a large number of algorithms, although the organization and coverage is superb, but with the analyses which accompany the algorithms. Many readers with some programming expertise could, if presented with a sketch of a method, devise good algorithms for its implementation. However, it is not the case that they would be able to specify quantitatively why one algorithm should be used in a particular situation in place of another. This is so even for those who are mathematicians. The reviewers know of no book on searching and/or sorting which approaches this book in scope and depth.

There is little doubt that here is a major work that every person working in or teaching programming or computer science must consult and, better yet, seriously read. It is a very worthwhile investment. Moreover, it is highly recommended that every under-

graduate computer science curriculum offer a course based on Volume 3. It is through scholarship such as evidenced by Professor Knuth's work that the science belongs in computer science.

MICHAEL T. McCLELLAN  
JACK MINKER

Department of Computer Science  
University of Maryland  
College Park, Maryland 20742

56 [12].—R. P. VAN DE RIET, *ABC Algol, A Portable Language for Formula Manipulation Systems*. Part I: *The Language*, Part II: *The Compiler*, Mathematisch Centrum, Amsterdam, 1973, Part I: iv + 173 pp. Price Dfl 18.—; Part II: 116 pp. Price Dfl 12.—.

The ABC Algol system is an extension of Algol 60 designed for algebraic manipulation, with some thought given to more general symbol manipulation. It is a small-scale system, not designed to compete with larger systems such as FORMAC or MATHLAB. It bears some resemblance to Perlis' old Formula Algol System [1], but is somewhat less general in the manipulations that it allows.

ABC Algol provides a datatype *formula*; values of this type can be symbolic expressions. Through an extension to the procedure-defining mechanism of Algol, operators can be defined on operands of type *formula*. The formula manipulation system consists of a set of such definitions, including facilities for manipulating rational numbers and performing a standardized kind of expression simplification.

The system is written in Algol and includes the necessary dynamic storage allocation features and a garbage collector as runtime procedure in Algol. The tract describing the system consists of two volumes, specifying the system and giving the full text of the algebraic manipulation system as well as the compiler.

This system does not seem to contribute anything new; it may be of some interest to specialists in algebraic manipulation because of its self-contained description and its portability. A summary of this publication can also be found in [2].

PAUL ABRAHAMS
