Spline Interpolation at Knot Averages on a Two-Sided Geometric Mesh*

By M. J. Marsden

Abstract. For splines of degree $k > 1$ with knots $-t_i = t_{2m+1-i} = 1 + q + q^2 + \cdots + q^{m-i}$, $i = 1, \dots, m$, where $0 < q < 1$, it is shown that spline interpolation to continuous functions at nodes $\tau_i = \sum_1^k w_j t_{i+j}$, $i = 1, \dots, n = 2m - k - 1$, has operator norm $\|P\|$ which is bounded independently of q and m as q tends to zero if and only if $(1 - w_1)^k < \frac{1}{2}$, $(1 - w_k)^k < \frac{1}{2}$, and $w_j > 0$, $j = 1, \dots, k$. The choice of nodes $\tau_i = \sum_0^{k+1} w_j t_{i+j}$ and the growth rate of $\|P\|$ with k are also discussed.

1. Two-Sided q -Splines. To integers $n > 0$, $k \geq 0$, and a nondecreasing sequence $\mathbf{t} = (t_i)_{i=1}^{n+k+1}$ with $t_i < t_{i+k+1}$, $i = 1, \dots, n$, is associated $\mathcal{S}_{k+1, \mathbf{t}}$, the space of polynomial splines of order $k + 1$ with knot sequence $\mathbf{t}$, defined by $\mathcal{S}_{k+1, \mathbf{t}} = \text{span}\{N_1, \dots, N_n\}$, where each $N_i = N_{i, k+1}$ is an appropriate normalized B -spline. See [1] for specific details.

With $q > 0$, m a positive integer, $n = 2m - k - 1$, and

$$(1.1) \quad \begin{aligned} t_i &= -(1 + q + \cdots + q^{m-i}), & i &= 1, \dots, m, \\ &= 1 + q + \cdots + q^{i-m-1}, & i &= m+1, \dots, 2m, \end{aligned}$$

$\mathcal{S}_{k+1, \mathbf{t}}$ is the space of *two-sided q -splines*.

Each two-sided q -spline can be represented as

$$(1.2) \quad \begin{aligned} s(t) &= \sum_1^{m-1} A_j [q^{j-m}(t_{j+1} - t)_+]^k + \sum_0^k A_{m+j} t^j \\ &\quad + \sum_1^{m-1} A_{m+k+j} [q^{-j}(t - t_{m+j})_+]^k, \end{aligned}$$

where $u_+ = \max\{u, 0\}$, with the endpoint conditions

$$(1.3) \quad s^{(i)}(t_1) = s^{(i)}(t_{2m}) = 0, \quad i = 0, \dots, k-1.$$

Conversely, each function of the form (1.2) which satisfies (1.3) is a two-sided q -spline.

With the notation

$$[i] = 1 + q + \cdots + q^{i-1}, \quad i = 0, 1, \dots,$$

relations such as

$$t_{j+1} - t_i = q^{m-j} [j+1-i], \quad 0 < i \leq j < m,$$

and

$$t_{i+1} - t_j = q^{j-m} [i + 1 - j], \quad m < j \leq i < 2m,$$

can be stated in a compact form. The notation

$$[i]! = [i][i-1] \cdots [2][1] \quad \text{and} \quad \begin{bmatrix} j \\ i \end{bmatrix} = \frac{[j]!}{[i]![j-i]!}$$

will also be useful.

The clause "as q tends to zero" appears throughout this paper. It will always mean "for all q satisfying $0 < q \leq q_0$ ". The specific choice of q_0 will vary from instance to instance. However, q_0 will never depend on m .

LEMMA 1.1. *With k and m fixed, let $\{s\}$ be a set of two-sided q -splines with $\{(A_1, \dots, A_{2m+k-1})\}$ the corresponding set of coefficient vectors in (1.2). Then $\{s\}$ is uniformly bounded as q tends to zero if and only if $\{(A_j)\}$ is uniformly bounded as q tends to zero. Moreover, if the bound on $\{s\}$ is independent of m , then so is the bound on $\{(A_j)\}$.*

Proof. Let $1 > q_0 > 0$ and C be such that

$$|A_j| \leq C, \quad \text{all } j \text{ and } 0 < q \leq q_0.$$

Then, for each real t and $0 < q \leq q_0$,

$$\begin{aligned} |s(t)| &\leq C \left(\sum_1^{m-1} [q^{j-m}(t_{j+1} - t_1)]^k + \sum_0^k t_{2m}^j + \sum_1^{m-1} [q^{-j}(t_{2m} - t_{m+j})]^k \right) \\ &= C \left(\sum_1^{m-1} [j]^k + \sum_0^k [m]^j + \sum_1^{m-1} [m-j]^k \right) \leq (2m+k-1)C[m]^k \\ &< (2m+k-1)Cm^k. \end{aligned}$$

Conversely, let $1 > q_0 > 0$ and B be such that

$$|s(t)| \leq B, \quad \text{all real } t \text{ and } 0 < q \leq q_0.$$

Since

$$\sum_0^k A_{m+j}(i/k)^j = s(i/k), \quad i = 0, \dots, k,$$

is a matrix equation with nonsingular coefficient matrix $V = ((i/k)^j)$ depending only on k ,

$$|A_{m+j}| \leq (k+1)B_k B, \quad j = 0, \dots, k,$$

where B_k is a bound on the entries of V^{-1} . Set $C_0 = (k+1)B_k B$ and assume inductively that q_1 is such that $|A_{m-j}| \leq C_j$ for $j = 0, 1, \dots, i-1$ for $q \leq q_1$. From (1.2)

$$\begin{aligned} s(t_{m-i}) - s(t_{m-i+1}) &= A_{m-i} + \sum_1^{i-1} A_{m-j}([i-j+1]^k - [i-j]^k) \\ &\quad + \sum_1^k A_{m+j}(-1)^j([i+1]^j - [i]^j), \end{aligned}$$

so that

$$\begin{aligned} |A_{m-i}| &\leq 2B + \sum_1^{i-1} C_j ([i-j+1]^k - [i-j]^k) + C_0 \sum_1^k ([i+1]^j - [i]^j) \\ &\leq 2B + \sum_1^{i-1} C_j q^{i-j} k (1-q_0)^{-k} + C_0 \sum_1^k q^j (1-q_0)^{-j} \\ &\leq 2B + \sum_0^{i-1} C_j q^{i-j} R_k \quad \text{with } R_k = k^2 (1-q_0)^{-k}. \end{aligned}$$

Setting $C_i = 2B + \sum_0^{i-1} C_j q^{i-j} R_k$ allows the induction to proceed. Then $C_1 = 2B + C_0 q_1 R_k$, and $C_{i+1} = q_1 (1 + R_k) C_i + 2B(1 - q_1)$, $i = 1, \dots, m-2$. This recurrence solves as

$$C_i = \frac{2B(1 - q_1)}{1 - q_1 - q_1 R_k} [1 - (q_1 + q_1 R_k)^{i-1}] + C_1 (q_1 + q_1 R_k)^{i-1},$$

$$i = 1, \dots, m-1,$$

if $q_1 + q_1 R_k \neq 1$. Imposing the added restriction $q_1 + q_1 R_k < \frac{1}{2}$ and noting that a symmetric argument will yield $|A_{m+k+j}| \leq C_j$, $j = 1, \dots, m-1$, establishes that

$$\max_j |A_j| \leq \max_i C_i \leq 4B + C_1 + C_0.$$

This bound is independent of m if B is independent of m . $\square$

LEMMA 1.2. Let k and m be fixed. As q tends to zero, the coefficients (A_j) satisfy

$$A_i + \sum_{i+1}^{m-1} A_j q^{(j-i)(k-i)} \begin{bmatrix} j \\ i \end{bmatrix} + \sum_{k-i}^k A_{m+j} O(q^{(m-i)(k-i)}) = 0, \quad i = 1, \dots, k-1,$$

and

$$A_k + \sum_{k+1}^{m-1} A_j \begin{bmatrix} j \\ k \end{bmatrix} + \sum_0^k A_{m+j} \left(\frac{t_1^j}{[k]!} + O(q^{m-k+1}) \right) = 0.$$

Proof. This follows from (1.3). Let functionals $\Lambda_{i\nu}$, $1 \leq i \leq \nu \leq k$, be defined by

$$\Lambda_{1\nu} s = q^{(m-1)(k-\nu)} \frac{\nu!}{k!} (-1)^{k-\nu} s^{(k-\nu)}(t_1)$$

and, recursively,

$$\Lambda_{i\nu} s = q^{\nu-k} (\Lambda_{i-1,\nu} s - [i-1] \Lambda_{i-1,\nu-1} s) / [i].$$

From (1.2)

$$\begin{aligned} s^{(k-\nu)}(t_1) &= \sum_1^{m-1} A_j q^{(j-m)(k-\nu)} \frac{k!}{\nu!} (-1)^{k-\nu} [j]^\nu \\ &\quad + \sum_{k-\nu}^k A_{m+j} \frac{j!}{(j-k+\nu)!} t_1^{j-k+\nu}, \end{aligned}$$

whence

$$\Lambda_{1\nu} s = \sum_1^{m-1} A_j q^{(j-1)(k-\nu)} [j]^\nu + \sum_{k-\nu}^k A_{m+j} q^{(m-1)(k-\nu)} C_{1j\nu},$$

where

$$C_{\nu\nu} = \frac{\nu!j!}{k!(j-k+\nu)!} (-1)^{k-\nu} t_1^{j-k+\nu}.$$

The recursion formula gives

$$\Lambda_{i\nu}s = \sum_i^{m-1} A_j q^{(j-i)(k-\nu)} [j]^{\nu-i} \begin{bmatrix} j \\ i \end{bmatrix} + \sum_{k-\nu}^k A_{m+j} q^{(m-i)(k-\nu)} C_{ij\nu},$$

where

$$C_{ij\nu} = (C_{i-1,j,\nu} - [i-1] q^{m-i+1} C_{i-1,j,\nu-1}) / [i].$$

From (1.3) each $\Lambda_{i\nu}s = 0$ and, in particular, $\Lambda_{ii}s = 0$. This fact, along with the observation that $C_{kjk} = C_{1jk}/[k]! + O(q^{m-k+1})$ completes the proof. $\square$

Combining Lemmas 1.1, 1.2, and a symmetric counterpart of Lemma 1.2 yields

LEMMA 1.3. *Let k and m be fixed and let $\{s\}$ be a set of two-sided q -splines which is bounded as q tends to zero. Then the corresponding set of coefficient vectors $\{(A_j)\}$ satisfies*

$$\begin{aligned} A_i &= O(q^{k-i}), & i &= 1, \dots, k-1, \\ A_i &= O(1), & i &= k, \dots, 2m, \\ A_{2m+i} &= O(q^i), & i &= 1, \dots, k-1, \end{aligned}$$

as q tends to zero. If the bound on $\{s\}$ is independent of m , then so are the bounds on the A_j .

The independence of m in the $O(q^{k-i})$ and $O(q^i)$ bounds follows from the exponential decay of the coefficients in the first $k-1$ equations of Lemma 1.2.

2. Spline Interpolation. Let $\tau = (\tau_i)_1^n$ be a strictly increasing sequence. It is known [1] that: For each function f defined on τ there is exactly one $s \in \mathfrak{S}_{k+1,t}$ such that $s(\tau_i) = f(\tau_i)$, $i = 1, \dots, n$, if and only if $N_i(\tau_i) > 0$, $i = 1, \dots, n$, or, equivalently, if and only if

$$(2.1) \quad t_i < \tau_i < t_{i+k+1}, \quad i = 1, \dots, n.$$

When τ satisfies (2.1) a linear map P into $\mathfrak{S}_{k+1,t}$ which reproduces $\mathfrak{S}_{k+1,t}$ may be defined by: For each function f defined on τ , $Pf \in \mathfrak{S}_{k+1,t}$ and $(Pf)(\tau_i) = f(\tau_i)$, $i = 1, \dots, n$. In fact, $Pf = \sum f(\tau_j) L_j$ where $(L_j)_1^n$ is defined by $L_j(\tau_i) = \delta_{ij}$, $i, j = 1, \dots, n$. The operator norm of P is

$$\|P\| = \sup_f \frac{\|Pf\|}{\|f\|},$$

where the sup is taken over all $f \in C[t_1, t_{n+k+1}]$ and

$$\|f\| = \sup\{|f(t)|: t_1 \leq t \leq t_{n+k+1}\}.$$

It is well known that

$$\|P\| = \max_t \sum_1^n |L_j(t)| = \max_{0 \leq \mu \leq n} \left(\max_{\tau_\mu \leq t \leq \tau_{\mu+1}} s_\mu(t) \right),$$

where $\tau_0 = t_1$, $\tau_{n+1} = t_{n+k+1}$ and $(s_\mu)_0^n$ is defined by

$$(2.2) \quad \begin{aligned} s_\mu(\tau_i) &= (-1)^{i+\mu}, & i &= 1, \dots, \mu, \\ &= -(-1)^{i+\mu}, & i &= \mu + 1, \dots, n. \end{aligned}$$

For each μ , the so-called Lebesgue function $\sum |L_i(t)|$ coincides with $s_\mu(t)$ on the interval $[\tau_\mu, \tau_{\mu+1}]$.

One way of specifying τ is to require that the nodes be knot averages, i.e.,

$$(2.3) \quad \tau_i = \sum_0^{k+1} w_j t_{i+j}, \quad i = 1, \dots, n,$$

where the w_j are fixed nonnegative numbers which sum to one.

THEOREM 1. *Let $k \geq 2$, m , and $(w_i)_0^{k+1}$ be fixed. Let $\mathbf{t}$ be given by (1.1) and τ be given by (2.3). If $\|P\|$ is bounded as q tends to zero, then*

$$(2.4) \quad w_i > 0, \quad i = 1, \dots, k.$$

If the bound on $\|P\|$ is also independent of m , then either

$$(2.5)a \quad w_0 = 0 \quad \text{and} \quad (1 - w_1)^k < \frac{1}{2}$$

or

$$(2.5)b \quad w_0 > 0 \quad \text{and} \quad \frac{1}{2} < (1 - w_0)^k$$

and, either

$$(2.6)a \quad w_{k+1} = 0 \quad \text{and} \quad (1 - w_k)^k < \frac{1}{2}$$

or

$$(2.6)b \quad w_{k+1} > 0 \quad \text{and} \quad \frac{1}{2} < (1 - w_{k+1})^k.$$

Conversely, if (2.4), (2.5), (2.6) hold, then $\|P\|$ is bounded independently of m as q tends to zero.

Proof. Let w_a be the first positive weight and w_b be the last positive weight, so that $\tau_i = \sum_a^b w_j t_{i+j}$, and set

$$\theta_1 = (1 - w_a) + (1 - w_a - w_{a+1})q + \dots + w_b q^{b-a-1},$$

$$\theta_2 = (1 - w_b) + (1 - w_b - w_{b-1})q + \dots + w_a q^{b-a-1}.$$

If $a = b$, then $\theta_1 = \theta_2 = 0$. If $a < b$, then $0 < \theta_1 < 1$ and $0 < \theta_2 < 1$ as q tends to zero. Therefore,

$$(2.7) \quad \begin{aligned} t_{i+b-1} &< \tau_i = t_{i+b} - \theta_2 q^{m+1-b-i} \leq t_{i+b}, & i &= 1, \dots, m-b, \\ t_{i+a} &\leq \tau_i = t_{i+a} + \theta_1 q^{i+a-m} < t_{i+a+1}, & i &= m-a+1, \dots, n, \end{aligned}$$

for all sufficiently small $q > 0$. Since

$$(2.8) \quad \tau_i = 1 - 2 \sum_a^{m-i} w_j + O(q), \quad i = m-b+1, \dots, m-a,$$

as q tends to zero, it follows that also

$$(2.9) \quad -1 < \tau_{m-b+1} < \tau_{m-b+2} < \dots < \tau_{m-a} < +1$$

for all sufficiently small $q > 0$.

Henceforth, we require that q be such that the inequalities in (2.7) and (2.9) hold. This requirement is independent of m .

Now let $\|P\|$ be bounded independently of m as q tends to zero. We shall prove that (2.4) and (2.6) must hold. A symmetric argument, which we omit, will give (2.5).

Let $s = s_\mu$ be defined by (2.2) with $\mu < m - b + 1$ or $\mu > m - a - 1$. There is a constant C which bounds $\|P\|$ so that $\|s\| \leq C$ as q tends to zero. Since the restriction of s to $[-1, +1]$ is a polynomial of degree k , it follows from a theorem of A. A. Markov (see [7]) that

$$\max\{|s'(t)|: -1 \leq t \leq 1\} \leq Ck^2.$$

Thus, (2.8), (2.9), and the mean-value theorem imply that

$$2 = |s(\tau_i) - s(\tau_{i+1})| \leq Ck^2(\tau_{i+1} - \tau_i) \leq 2Ck^2w_{m-i} + O(q)$$

for $i = m - b + 1, \dots, m - a - 1$ as q tends to zero. Thus, $w_i \geq 1/Ck^2 > 0$, $i = a + 1, \dots, b - 1$.

Suppose that $b < k$. Then, on the one hand, (1.2) gives

$$\begin{aligned} \pm 1 = s(\tau_1) &= \sum_b^{m-1} A_j([j - b] + \theta_2 q^{j-b})^k + \sum_0^k A_{m+j}(-[m - b] - \theta_2 q^{m-b})^j \\ &= A_b \theta_2^k + \sum_{b+1}^{m-1} A_j([j - b]^k + O(q^{j-b})) \\ &\quad + \sum_0^k A_{m+j}((-[m - b])^j + O(q^{m-b})), \end{aligned}$$

whereas, on the other hand, with $\Lambda_{ii}s$ as in the proof of Lemma 1.2,

$$\begin{aligned} 0 &= \theta_2^k \Lambda_{bb}s + \sum_{b+1}^{k-1} [i - b]^k \Lambda_{ii}s + [k]! \Lambda_{kk}s \\ &= A_b \theta_2^k + \sum_{b+1}^{m-1} A_j([j - b]^k + O(q^{j-b})) \\ &\quad + \sum_0^k A_{m+j}((-[m - b])^j + O(q^{m-b})). \end{aligned}$$

Subtraction yields

$$\pm 1 = \sum_{b+1}^{m-1} A_j O(q^{j-b}) + \sum_0^k A_{m+j} O(q^{m-b}),$$

so that (A_j) cannot be bounded as q tends to zero. This contradiction to Lemma 1.3 shows that $b \geq k$.

A similar argument with $s(\tau_n)$ shows that $a \leq 1$, so that (2.4) is proved.

To prove (2.6), we first suppose that $w_{k+1} = 0$. We must show that $(1 - w_k)^k < \frac{1}{2}$ or, equivalently, that

$$(2.10) \quad r_2 = \theta_2^k / (1 - \theta_2^k) < 1 \quad \text{as } q \text{ tends to zero.}$$

Again, let $s = s_\mu$ be defined by (2.2). Then Lemma 1.2 and (1.2) give

$$(2.11) \quad -s(\tau_1) = [k]! \Lambda_{kk}s - s(\tau_1) = \sum_0^{m-k-1} M_{0j} A_{k+j} + \sum_0^k R_{0j} A_{m+j}$$

and

$$(2.12) \quad s(\tau_i) - s(\tau_{i+1}) = \sum_{j=1}^{m-k-1} M_{ij} A_{k+j} + \sum_0^k R_{ij} A_{m+j}, \quad i = 1, \dots, m-k-1,$$

where

$$\begin{aligned} M_{0j} &= [k+j]!/[j]! - ([j] + \theta_2 q^j)^k, \quad j = 0, \dots, m-k-1, \\ M_{i,i-1} &= \theta_2^k, \quad i = 1, \dots, m-k-1, \\ M_{ij} &= ([j-i+1] + \theta_2 q^{j-i+1})^k - ([j-i] + \theta_2 q^{j-i})^k, \\ &\quad i = 1, \dots, m-k-1; j = i, \dots, m-k-1, \\ R_{0j} &= [k]! C_{kjk} - \tau_1^j, \quad j = 0, \dots, k, \\ R_{ij} &= \tau_i^j - \tau_{i+1}^j, \quad i = 1, \dots, m-k-1; j = 0, \dots, k, \end{aligned}$$

with $C_{kjk} = t_1^k/[k]! + O(q^{m-k+1})$ as in the proof of Lemma 1.2.

Since the A_j are bounded and

$$\begin{aligned} M_{ii} &= 1 - \theta_2^k + O(q), \quad i = 0, \dots, m-k-1, \\ M_{0j} &< [k+j]^k - [j]^k < q^j [k] k [k+j]^{k-1} < q^j k (1-q)^{-k}, \\ M_{ij} &< [j-i+2]^k - [j-i]^k < q^{j-i} k (1-q)^{-k}, \\ &\quad j = i+1, \dots, m-k-1, \end{aligned}$$

$$|R_{0j}| < q^{m-k}(j+1)(1-q)^{-j},$$

$$|R_{ij}| \leq q^{m-k-i} j (1-q)^{-j},$$

the system (2.11) and (2.12) has the form

$$(1 - \theta_2^k) A_k = -s(\tau_1) + O(q),$$

$$\theta_2^k A_{k+i-1} + (1 - \theta_2^k) A_{k+i} = s(\tau_i) - s(\tau_{i+1}) + O(q), \quad i = 1, \dots, m-k-1,$$

which solves as

$$\begin{aligned} A_{k+i} &= \frac{2(-1)^{i+\mu}}{1 - 2\theta_2^k} \left[1 - \frac{r_2^{i+1}}{2\theta_2^k} \right] + O(q), \\ &\quad i = 0, \dots, \min(\mu-1, m-k-1), \\ (2.13) \quad A_{k+\mu+i} &= \frac{2(-1)^{i+1}}{1 - 2\theta_2^k} \left[1 - \frac{r_2^{i+1}}{\theta_2^i} + \frac{r_2^{i+\mu+1}}{2\theta_2^k} \right] + O(q), \\ &\quad i = 0, \dots, m-k-1-\mu, \end{aligned}$$

if $r_2 \neq 1$ and as

$$\begin{aligned} A_{k+1} &= (-1)^{i+1} (2 + 4i) + O(q), \quad i = 0, \dots, \min(\mu-1, m-k-1), \\ A_{k+\mu+i} &= (-1)^{i+1} (2 + 4i - 4\mu) + O(q), \quad i = 0, \dots, m-k-1-\mu, \end{aligned}$$

if $r_2 = 1$ provided that the buildup of $O(q)$ terms is bounded independently of m . This will be the case if $qr_2 < 1$ as q tends to zero, a condition that can be met independently of m . By Lemma 1.3 these A_j are bounded independently of m . Therefore, (2.10) must hold and $(1 - w_k)^k < \frac{1}{2}$.

To complete the proof of (2.6) we now suppose that $w_{k+1} > 0$. Since $\theta_2 = 1 - w_{k+1} + O(q)$, we must now show that $\theta_2^k > \frac{1}{2}$ as q tends to zero, that is

$$(2.14) \quad r_2 = \theta_2^k / (1 - \theta_2^k) > 1 \quad \text{as } q \text{ tends to zero.}$$

Since the τ_i have "moved over one interval", Eqs. (2.11) and (2.12) are replaced by

$$(2.15) \quad \begin{aligned} -s(\tau_1) = [k]!A_k + \sum_1^{m-k-1} ([k+j]!/ [j]! - ([j-1] + \theta_2 q^{j-1})^k) A_{k+j} \\ + \sum_0^k R_{0j} A_{m+j} \end{aligned}$$

and

$$(2.16) \quad \begin{aligned} s(\tau_i) - s(\tau_{i+1}) = \sum_i^{m-k-1} M_{i,j-1} A_{k+j} + \sum_0^k R_{ij} A_{m+j}, \\ i = 1, \dots, m-k-2, \end{aligned}$$

and the bounds on M_{0j} and R_{ij} are replaced by

$$\begin{aligned} |[k+j]!/ [j]! - ([j-1] + \theta_2 q^{j-1})^k| &< q^{j-1} k(1-q)^{-k}, \\ |R_{0j}| &< q^{m-k-1} (j+1)(1-q)^{-j}, \\ |R_{ij}| &\leq q^{m-k-1-j} (1-q)^{-j}. \end{aligned}$$

This incomplete system now has the form

$$\begin{aligned} A_k + (1 - \theta_2^k) A_{k+1} &= -s(\tau_1) + O(q), \\ \theta_2^k A_{k+i} + (1 - \theta_2^k) A_{k+i+1} &= s(\tau_i) - s(\tau_{i+1}) + O(q), \quad i = 1, \dots, m-k-2. \end{aligned}$$

Adding the equation

$$(2.17) \quad s(\tau_{m-k-1}) = A_{m-1} \theta_2^k + \sum_0^k A_{m+j} \tau_{m-k-1}^j = A_{m-1} \theta_2^k + s(-1) + O(q)$$

and imposing the restriction $qr_2^{-1} < 1$ permits us to solve this system backwards in terms of $s(-1)$ as

$$(2.18) \quad \begin{aligned} A_{m-i} &= \frac{(-1)^{m-1-k-\mu-i}}{2\theta_2^k - 1} [2 - (1+r_2)r_2^{-i}] + (1+r_2)(-r_2)^{-i} s(-1) \\ &\quad + O(q), \quad i = 1, \dots, m-k-1-\mu, \\ A_{k+\mu+1-i} &= \frac{(-1)^{i-1}}{2\theta_2^k - 1} [2 - (1+r_2)r_2^{-i} (2 - r_2^{-m+k+\mu+1})] \\ &\quad + (1+r_2)(-r_2)^{-m+k+\mu+1-i} s(-1) + O(q), \quad i = 1, \dots, \mu, \end{aligned}$$

if $0 \leq \mu \leq m-k-2$ and as

$$(2.19) \quad \begin{aligned} A_{m-i} &= \frac{(-1)^{\mu-m+k-i}}{2\theta_2^k - 1} [2 - (1+r_2)r_2^{-i}] \\ &\quad + (1+r_2)(-r_2)^{-i} s(-1) + O(q), \quad i = 1, \dots, m-k-1, \end{aligned}$$

if $\mu \geq m-k-1$. Since the A_j are bounded independently of m , (2.14) must hold and $(1 - w_{k+1})^k > \frac{1}{2}$.

The proof that (2.4), (2.5), (2.6) are necessary conditions for $\|P\|$ to be bounded independently of m as q tends to zero is complete.

To prove that (2.4), (2.5), (2.6) are sufficient that $\|P\|$ be bounded independently of m as q tends to zero, we will use the approach outlined in the proof of Lemma 1.1. That is, we will first show that, for each $s = s_\mu$, the block $A_m, \dots, A_{m+k}$ is bounded and then argue recursively from bounds on $s(\tau_i)$ (replacing $s(t_i)$ in the proof of Lemma 1.1) that A_{m-i} (and A_{m+k+i}), $i = 1, \dots, m-1$, are bounded independently of m . Finally, we will use (1.2) and (2.13) or (2.18) or (2.19) to bound $s_\mu(t)$ for all t and all μ .

If $a = 0$ and $b = k + 1$, the first step, bounding the block $A_m, \dots, A_{m+k}$ is easy since (2.9) implies that

$$(2.20) \quad \sum_0^k A_{m+j} \tau_{m-k+i}^j = \pm 1, \quad i = k+1-b, \dots, k-a,$$

and (2.4), (2.8) give a bounded inverse for the Vandermonde matrix (τ_{m-k+i}^j) . However, if $b = k$ then the $i = 0$ equation of (2.20) is replaced by

$$(2.21) \quad \theta_2^k A_{m-1} + \sum_0^k A_{m+j} \tau_{m-k}^j = \pm 1.$$

If $a = 1$, there is a similar replacement of

$$(2.22) \quad \sum_0^k A_{m+j} \tau_m^j + \theta_1^k A_{m+k+1} = \pm 1$$

for the $i = k$ equation of (2.20).

Therefore, if $b = k$ (and/or $a = 1$), a preliminary step to eliminate $\theta_2^k A_{m-1}$ from (2.21), at the expense of adding a bounded quantity to the right member, is necessary. While eliminating $\theta_2^k A_{m-1}$ through a sequence of upper triangulation steps on (2.11), (2.12), (2.21) is straightforward, there must be an argument that $\theta_2^k A_{m-1}$ is bounded independently of m as q tends to zero independently of m . The following lines supply this argument.

Let $b = k$ and let s be any of the s_μ given by (2.2). Using the bounds on $M = (M_{ij})$, we see that this matrix is diagonally dominant if q is such that $1 - \theta_2^k > \theta_2^k + kq(1 - q)^{-k-1}$. But (2.5) a is equivalent to $1 - \theta_2^k > \theta_2^k$ for sufficiently small q , so that this condition can be met by imposing a further restriction on q .

Let $q_0 > 0$ and $\delta > 0$ be such that $\delta = 1 - 2\theta_2^k - kq_0(1 - q_0)^{-k-1}$. Then the solutions of a system

$$M\mathbf{x} = \mathbf{b}$$

satisfy $\max_i |x_i| \leq \delta^{-1} \max_i |b_i|$ by the usual diagonal dominance argument. Applying this fact with

$$\begin{aligned} b_0 &= [k]! \Lambda_{kk} s - s(\tau_1) = -s(\tau_1), \\ b_i &= s(\tau_i) - s(\tau_{i+1}), \quad i = 1, \dots, m-k-1, \end{aligned}$$

as well as with

$$b_i = -R_{ij}, \quad i = 0, \dots, m-k-1,$$

for each $j = 0, \dots, k$, yields

$$A_{m-1} = C + \sum_0^k C_j A_{m+j}$$

with

$$\begin{aligned} |C| &\leq \delta^{-1} \max\{|s(\tau_1)|, |s(\tau_i) - s(\tau_{i+1})|: i = 1, \dots, m-k-1\} = 2/\delta, \\ |C_0| &\leq \delta^{-1} \max_i |R_{i0}| = |R_{00}|/\delta = O(q^{m-k}), \\ |C_j| &\leq \delta^{-1} \max_i |R_{ij}| = |\tau_{m-k-1}^j - \tau_{m-k}^j|/\delta \\ &= |(1+q+\theta_2 q^2)^j - (1+\theta_2 q)^j|/\delta < q[2]^j[3]^{j-1}/\delta \\ &< qj[3]^j/\delta = O(q), \quad j = 1, \dots, k. \end{aligned}$$

Combining these deductions with (2.21) gives the equation

$$(2.23) \quad \sum_0^k A_{m+j}(\tau_{m-k}^j + C_j \theta_2^k) = s(\tau_{m-k}) - C \theta_2^k,$$

which can be adjoined to (2.20). Since $C_j = O(q)$ and $\tau_{m-k+1} - \tau_{m-k} = 2w_k + O(q)$, the resulting system has a bounded solution as q tends to zero. We have assumed that $a = 0$. If $a = 1$, a similar argument at τ_m is needed.

We have completed the first step in the proof of sufficiency, i.e., we have shown that the set $A_m, \dots, A_{m+k}$ is bounded. But now (2.12) or (2.16) and their symmetric counterparts imply immediately that the set $A_k, \dots, A_{2m}$ is bounded. An argument similar to the proof of Lemma 1.2 gives $O(q^i)$ bounds on A_{k-i} and A_{2m+i} , $i = 1, \dots, k-1$. The second step in the proof is completed.

Now we must bound $s_\mu(t)$ for all t and all μ . For $-1 \leq t \leq +1$, the boundedness of $A_m, \dots, A_{m+k}$ and (2.4) give a uniform bound on $s_\mu(t)$. If $t_1 \leq t \leq t_m$, there is a θ_i in $[0, 1]$ and an $i > 0$ such that $t_{m-i} \leq t = t_{m-i+1} - \theta_i q^i = -[i] - \theta_i q^i < t_{m-i+1}$. Then

$$s(t) = \sum_{m-i}^{m-1} A_j([i+j-m] + \theta_i q^{i+j-m})^k + \sum_0^k A_{m+j} t^j.$$

If $i \leq m-b$, then $\tau_{m+1-b-i} = -[i] - \theta_2 q^i$ and

$$|s(t)| \leq |s(\tau_{m+1-b-i})| + |A_{m-i}| + O(q) = 1 + |A_{m-i}| + O(q)$$

can be easily shown. If $i > m-b$, a modified argument gives

$$|s(t)| \leq |s(\tau_1)| + \sum_1^k |A_j| + O(q) = 1 + |A_k| + O(q).$$

Thus, the $s_\mu(t)$ are uniformly bounded for all μ and all t so that $\|P\|$ is bounded independently of m as q tends to zero. $\square$

3. Two Special Cases. Theorem 1 provides counterexamples when (2.4), (2.5), (2.6) are not satisfied, e.g., interpolation at the knots with $k \geq 2$ or interpolation at weighted two-knot averages with $k \geq 3$. The condition that q tend to zero compares (contrasts?) with the often-used condition that the local mesh ratios $(t_{j+1} - t_j)/(t_{i+1} - t_i)$, $|i-j| = 1$ be bounded.

For $k \geq 3$ and $q = 1$, it is easy to select weights w_j satisfying (2.4), (2.5), (2.6) which still produce unbounded spline interpolation. Thus, even for two-sided q -splines, these conditions are not sufficient to guarantee bounded interpolation. Indeed, the method of their derivation suggests that they are linked quite closely to the tendency of q to zero.

For the two special cases which follow it is not clear that we need q to tend to zero. Computational evidence with small k suggests, in fact, that q tending to zero gives "worst-case" results. Thus, Theorems 2 and 3 are imperfect in that the condition that q tend to zero may be superfluous.

THEOREM 2. *Let $\mathbf{t}$ be given by (1.1) and, for each $k \geq 1$ and $m > k$, let τ be given by*

$$(3.1) \quad \tau_i = (t_{i+1} + t_{i+2} + \cdots + t_{i+k})/k, \quad i = 1, \dots, n.$$

Then, $\|P\|$ is bounded as q tends to zero. Moreover, there exist absolute constants $1 < C_1 < C_2$ such that, for each $k \geq 2$,

$$C_1^k < \|P\| < C_2^k \quad \text{as } q \text{ tends to zero.}$$

THEOREM 3. *Let $\mathbf{t}$ be given by (1.1) and, for each $k \geq 1$ and $m > k$, let τ be given by (2.3) with*

$$(3.2) \quad \begin{aligned} w_0 &= w_{k+1} = \sin^2(\alpha_k/2), \\ w_j &= \sin(\alpha_k)\sin(2j\alpha_k), \quad j = 1, \dots, k, \end{aligned}$$

where $\alpha_k = \pi/(2k+2)$. Then, $\|P\|$ is bounded as q tends to zero. Moreover, there exist absolute constants $0 < C_3 < C_4$ such that, for each $k \geq 2$,

$$C_3 \log k < \|P\| < C_4 \log k \quad \text{as } q \text{ tends to zero.}$$

Proof of Theorems 2 and 3. The assertions that $\|P\|$ is bounded as q tends to zero are proved by showing that (2.4), (2.5), (2.6) hold. These follow readily, since, in Theorem 2,

$$(1 - w_k)^k = (1 - w_1)^k = (k-1)^k/k^k < 1/e < 3/8$$

while, in Theorem 3,

$$\begin{aligned} (1 - w_{k+1})^k &= (1 - w_0)^k = \cos^{2k}(\alpha_k/2) > (1 - \alpha_k^2/8)^{2k} \\ &> 1 - \pi\alpha_k/8 > (8k+3)/(8k+8) > 3/4. \end{aligned}$$

In Theorem 2, the lower bound on $\|P\|$ follows from the fact that, as q tends to zero, the nodes

$$\tau_{m-k+1}, \tau_{m-k+2}, \dots, \tau_{m-k+j}, \dots, \tau_{m-1}$$

tend to

$$(2-k)/k, (4-k)/k, \dots, (2j-k)/k, \dots, (k-2)/k,$$

and that, for $s = s_\mu$ with $m-k \leq \mu \leq m-1$,

$$|s(\pm 1)| = (1 - r_2^{m-k})/(1 - 2\theta_2^k) + O(q) \geq 1/(1 - \theta_2^k) + O(q) > 1,$$

so that $\|P\|$ is bounded below by any lower bound for polynomial interpolation on $[-1, +1]$ at the equally-spaced nodes

$$-1, (2-k)/k, (4-k)/k, \dots, (2j-k)/k, \dots, (k-2)/k, +1.$$

See Rivlin [7, pp. 96–99] for a proof that such polynomial interpolation grows exponentially.

Similarly, in Theorem 3, the lower bound on $\|P\|$ follows from the fact that $\tau_{m-k}, \dots, \tau_m$ approach the Chebyshev nodes $-\cos(2j\alpha_k - \alpha_k)$, $j = 1, \dots, k+1$, as q tends to zero and the fact that polynomial interpolation on these nodes has logarithmic growth. See [7, pp. 93–96].

To complete the proof that $\|P\|$ grows exponentially or logarithmically in Theorem 2 or Theorem 3, respectively, it is necessary only to show that, for each μ , $s_\mu(t)$ is “controlled” outside $(-1, +1)$. This fact follows from the closing lines of the proof of Theorem 1, where it was noted that, for $t_1 \leq t \leq t_m$, there is a $j < m$ such that $|s(t)| \leq 1 + |A_j| + O(q)$. For Theorem 2, (3.1) and (2.13) imply that

$$\max_{j < m} |A_j| < \frac{2}{1 - 2\theta_2^k} + O(q) < \frac{2e}{e - 2} + O(q) < 8,$$

so that $|s(t)| < 10$ for $t \leq -1$ as q tends to zero. For Theorem 3, (3.2) and (2.18), (2.19) imply that

$$\begin{aligned} \max_{j < m} |A_j| &< \frac{2}{2\theta_2^k - 1} + 2|s(-1)| + O(q) \\ &< \frac{2}{2 \cos^{2k}(\alpha_k/2) - 1} + 2|s(-1)| + O(q) \\ &< 4 + 2|s(-1)| + O(q), \end{aligned}$$

so that $|s(t)| < 6 + 2|s(-1)|$ for $t \leq -1$ as q tends to zero. Symmetry considerations give like bounds for $|s(t)|$ on $+1 = t_{m+1} \leq t \leq t_{2m}$.

The proof of Theorem 2 and Theorem 3 is complete. $\square$

If $q = 1$ (not covered by these theorems), two-sided q -spline interpolation is essentially the same as cardinal spline interpolation, for which logarithmic growth of $\|P\|$ with k has been demonstrated; see [6]. This fact supports the conjecture that q tending to zero gives “worst-case” results for the nodes (3.1).

For cubic spline interpolation with arbitrary knot spacing and the nodes (3.1), de Boor [2] has shown that $\|P\| < 27$. He conjectures that $\|P\| < 3$ or 4 may be true. The following supplies a lower bound on $\limsup \|P\|$, where the $\limsup$ is taken over all ordered knot spacings.

THEOREM 4. *Let $k = 3$ and let $\mathbf{t}$ and $\boldsymbol{\tau}$ be given by (1.1) and (3.1), respectively. Then*

$$\lim \|P\| = (222\sqrt{111} + 999)/1331 = 2.507825 \dots,$$

where $\lim \|P\|$ denotes the limiting value of $\|P\|$ as q tends to zero and m tends to infinity.

Proof. Let $s = s_\mu$ with $\mu = m - 1$. From (2.21) and (2.13)

$$(3.3) \quad s(-1) = \frac{(-1)^{\mu-m+k}}{1 - 2\theta_2^k} (1 - r_2^{m-k}) + O(q)$$

for each $k \geq 2$ and $\mu \geq m - k$. Similarly,

$$(3.4) \quad s(+1) = \frac{(-1)^{m-1-\mu}}{1-2\theta_1^k} (1 - r_1^{m-k}) + O(q)$$

for $k \geq 2$ and $\mu \leq m - 1$. Thus, for the case presently under consideration, $s(t)$ tends, on $[-1, +1]$, to the cubic $p(t)$ satisfying $p(\pm 1) = 27/11$ and $p(\pm 1/3) = \pm 1$. This cubic is

$$p(t) = (-297t^3 + 243t^2 + 297t - 27)/88.$$

It has a maximum on $[-1, +1]$ of $(222\sqrt{111} + 999)/1331$ at $t = (9 + 2\sqrt{111})/33$. Showing that $\lim \|P\|$ exists and is equal to this maximum requires a discussion (which we omit) similar to the last paragraph in the proof of Theorem 1 above. $\square$

For arbitrary k it is easy to find $p(t)$, the polynomial which $s_{m-1}(t)$ approaches as q tends to zero and m tends to infinity. From (3.1) and (3.4)

$$\lim s(+1) = z_k = \frac{1}{1 - 2((k-1)/k)^k}.$$

From (3.3), $\lim s(-1) = (-1)^{k-1} z_k$. Then standard combinatorial formulas give (see Gould [4, p. 59])

$$p(t) = -(-1)^l \sum_0^l \frac{(-4)^j T}{T+j} \binom{T+j}{2j} + \frac{2T + kz_k}{T+l} \binom{T+l}{2l},$$

if k is even with $l = k/2$ and $T = lt$, and

$$p(t) = -(-1)^l \sum_0^l \frac{(-4)^j 2T}{2j+1} \binom{T+j-1/2}{2j} + \frac{2T + kz_k}{k} \binom{T+l-1/2}{2l},$$

if k is odd with $l = (k-1)/2$ and $T = kt/2$. The maximum of $p(t)$ on $(k-2)/k \leq t \leq +1$ is a good lower bound on $\|P\|$ as q tends to zero and m tends to infinity.

The following table was computed via double-precision arithmetic in FORTRAN on an Amdahl 470/V7 computer. All entries are rounded down.

Lower bounds on $\lim \sup \|P\|$

k	$\max p(t)$	k	$\max p(t)$	k	$\max p(t)$	k	$\max p(t)$
2	2.0000	7	7.7939	12	9.02×10	27	9.45×10^5
3	2.5078	8	11.8194	15	5.13×10^2	30	6.60×10^6
4	3.0814	9	18.7344	18	3.17×10^3	33	4.67×10^7
5	3.9686	10	30.7986	21	2.05×10^4	36	3.34×10^8
6	5.4087	11	52.1254	24	1.37×10^5	39	2.42×10^9

This table, in which the exponential growth is clear, is associated with Theorem 2 above. A corresponding table of lower bounds on $\lim \sup \|P\|$ for the node assignment of Theorem 3 can be computed from the fact that the Lebesgue function for polynomial interpolation on the Chebyshev nodes attains its maximum

at $t = 1$; see [7, Eq. (4.2.19)]. The first few entries of such a table are:

$$(1, 1.414) \quad (2, 1.666) \quad (3, 1.847) \quad (4, 1.988) \quad (5, 2.104) \quad (6, 2.202).$$

A later entry is (35, 3.243). The logarithmic growth is clear. For $k = 1$ with arbitrary knots it can be shown that $\|P\| \leq \sqrt{2}$ when nodes are specified by (3.2) above. Whether the other bounds are "good" bounds for the arbitrary knot case is problematical.

4. Remarks. For one-sided q -splines with spline knots $t_i = (1 - q^i)/(1 - q)$, $i = \dots, -1, 0, 1, 2, \dots$, and interpolation nodes $\tau_i = t_i + \theta q^i$, where θ is fixed, $0 < \theta < 1$, S. L. Lee [5] has considered eigensplines, i.e., nontrivial splines $s(t)$ satisfying $s(t) = \lambda s(1 + qt)$ for some fixed eigenvalue λ . Setting $\lambda = -1$ yields, for each $k \geq 2$, a certain equation $F_k(q, \theta) = 0$. If q and either θ_1 or θ_2 defined above satisfy this equation, then two-sided q -spline interpolation is unbounded. Lee [5] has shown that $F_k(0 + , \theta) = C[2\theta^k - 1][2(1 - \theta)^k - 1]$.

For quadratic splines with arbitrary knots t_i , Demko [3] has shown that interpolation is bounded independently of t_i and τ_i if the nodes τ_i satisfy $\tau_i = t_{i+2} - \lambda_i(t_{i+2} - t_{i+1})$ with $\lambda_i^2 \leq \gamma < \frac{1}{2}$ and $(1 - \lambda_i)^2 \leq \gamma < \frac{1}{2}$. Consequently, for $k = 2$, the results of Theorem 1 above with (2.5)a and (2.6)a are valid for all q and not just as q tends to zero.

Acknowledgement. I would like to thank S. D. Riemenschneider and A. Sharma for much useful advice while I was working on this problem.
