Numerical Stability of the Halley-Iteration for the Solution of a System of Nonlinear Equations

By Annie A. M. Cuyt*

Abstract. Let $F: \mathbb{R}^q \rightarrow \mathbb{R}^q$ and x^* a simple root in $\mathbb{R}^q$ of the system of nonlinear equations $F(x) = 0$.

Abstract Padé approximants (APA) and abstract Rational approximants (ARA) for the operator F have been introduced in [2] and [3]. The adjective "abstract" refers to the use of abstract polynomials [5] for the construction of the rational operators.

The APA and ARA have been used for the solution of a system of nonlinear equations in [4]. Of particular interest was the following third order iterative procedure:

$$x_{i+1} = x_i + \frac{a_i^2}{a_i + \frac{1}{2} F_i'^{-1} F_i'' a_i^2},$$

with F_i' the 1st Fréchet-derivative of F in x_i , $a_i = -F_i'^{-1} F_i$ the Newton-correction where $F_i = F(x_i)$, F_i'' the 2nd Fréchet-derivative of F in x_i where $F_i'' a_i^2$ is the bilinear operator F_i'' evaluated in (a_i, a_i) , and componentwise multiplication and division in $\mathbb{R}^q$. For $q = 1$ this technique is known as the Halley-iteration [6, p. 91]. In this paper the numerical stability [7] of the Halley-iteration for the case $q > 1$ is investigated and illustrated by a numerical example.

1. Numerical Stability of Iterations. We consider the numerical solution of the equation

$$(1) \quad F(x) = 0$$

with $F: \mathbb{R}^q \rightarrow \mathbb{R}^q: x \rightarrow F(x)$, abstract analytic in 0 [5]. Assume that (1) has a simple root x^* .

We briefly repeat the definition of condition-number given by Woźniakowski [7]. The condition-number should measure the sensitivity of the solution (output) with respect to changes in the data (input). We assume that F depends parametrically on a vector $d \in \mathbb{R}^p$, called data vector

$$F(x) = F(x; d),$$

and instead of the exact value $F(x; d)$ we only have the computed value $\text{fl}(F(x; d))$ in t digit floating-point binary arithmetic. At best we can expect that $\text{fl}(F(x; d))$ is the exact value of a slightly perturbed operator at slightly perturbed data

$$(2) \quad \text{fl}(F(x; d)) = (I + \Delta F)F(x + \Delta x; d + \Delta d),$$

where I is the $q \times q$ unit-matrix and

$$\begin{aligned} \|\Delta x\| &\leq C_1 \rho \|x\|, & \|\Delta d\| &\leq C_2 \rho \|d\|, \\ \|\Delta F\| &\leq C_3 \rho \quad (\Delta F \text{ a } q \times q \text{ matrix}), \end{aligned}$$

for constants C_1, C_2, C_3 (only depending on the dimensions of the problem) and with $\rho = 2^{-t}$ the relative computer precision [8]. By introducing the Landau-symbol O , we could also write

$$\Delta x = O(\rho), \quad \Delta d = O(\rho), \quad \Delta F = O(\rho),$$

where the constants in the Landau-notation depend on x, d and the dimensions. We will always, for a given F , define the data vector so that (2) holds and so that the condition number (see Definition 1.1) is minimized. Let $\text{fl}(d)$ denote the t digit binary representation of the vector d in floating-point arithmetic

$$\|\text{fl}(d) - d\| \leq C\rho\|d\|, \quad \text{i.e. } \text{fl}(d) - d = O(\rho).$$

Since d is represented by $\text{fl}(d)$, we solve in fact $F(x; \text{fl}(d)) = 0$ instead of $F(x) = 0$, independent of the method used to solve (1). Let F'_x and F'_d denote the partial Fréchet-derivatives of F , respectively with respect to x and d .

Now $F(x; \text{fl}(d)) = 0$ has a root $\tilde{x}^*$ in the neighborhood of x^* and $\tilde{x}^* - x^* = O(\rho)$ if t is sufficiently large; thus,

$$\begin{aligned} \tilde{x}^* - x^* &= -F'_x(x^*; d)^{-1} F'_d(x^*; d)(\text{fl}(d) - d) \\ &\quad + \text{higher order terms in } \tilde{x}^* - x^* \text{ and } \text{fl}(d) - d \\ &= -F'_x(x^*; d)^{-1} F'_d(x^*; d)(\text{fl}(d) - d) + O(\rho^2), \end{aligned}$$

where the constant in the Landau-notation depends on x^*, d and F .

For $x^* \neq 0$: $\|\tilde{x}^* - x^*\|/\|x^*\| \leq \|F'_x(x^*; d)^{-1} F'_d(x^*; d)\| C\rho\|d\|/\|x^*\| + O(\rho^2)$.

Definition 1.1. $\text{Cond}(F; d) = \|F'_x(x^*; d)^{-1} F'_d(x^*; d)\| \cdot \|d\|/\|x^*\|$ is called the *condition number of F with respect to the data vector d* .

A problem is ill-conditioned if $\text{cond}(F; d) \gg 1$.

Let us now suppose that $F(x; d) = 0$ is solved by an iterative procedure $\Phi(x_i, F)$, where Φ can use several $F_i^{(j)}$, the j th Fréchet-derivative of F at x_i (if $j = 1$ or 2, a single or double prime is used instead of the superscript j). If $\{x_i\}$ is the sequence of successive approximations of x^* , we can at best expect x_i to be the representation of a computed value for $\tilde{x}^*$,

$$\|x_i - \tilde{x}^*\| \leq K\rho\|\tilde{x}^*\|.$$

So

$$\begin{aligned} \|x_i - x^*\| &\leq \|x_i - \tilde{x}^*\| + \|\tilde{x}^* - x^*\| \leq K\rho\|\tilde{x}^*\| + C\rho \text{cond}(F; d) \cdot \|x^*\| + O(\rho^2) \\ &\leq K\rho(\|\tilde{x}^* - x^*\| + \|x^*\|) + C\rho \text{cond}(F; d) \cdot \|x^*\| + O(\rho^2) \\ &\leq [K\rho + C\rho \text{cond}(F; d)] \cdot \|x^*\| + O(\rho^2). \end{aligned}$$

Definition 1.2. An iteration Φ is called *numerically stable* if

$$\lim_{i \rightarrow \infty} \|x_i - x^*\| \leq \rho \cdot \|x^*\| \cdot (C \text{cond}(F; d) + K) + O(\rho^2),$$

where the constants C and K depend on x^*, d and F .

In practice we often want to find an approximation x_i such that $\|x_i - x^*\| \leq \varepsilon \cdot \|x^*\|$. This is possible if the problem is sufficiently well-conditioned, i.e., $\rho \text{cond}(F; d) = O(\varepsilon)$. In floating-point arithmetic we have

$$x_{i+1} = \Phi(x_i, F) + \xi_i, \quad \text{where } \xi_i = \text{fl}(\Phi(x_i, F)) - \Phi(x_i, F).$$

THEOREM 1.1. *A convergent iterative procedure $\Phi(x_i, F)$, i.e.*

$$\lim_{i \rightarrow \infty} \|\Phi(x_i, F) - x^*\| = 0,$$

is numerically stable if $\lim_{i \rightarrow \infty} \|\xi_i\| \leq \rho \|x^\| (C \operatorname{cond}(F; d) + K) + O(\rho^2)$.*

Proof. We simply verify the definition.

$$\begin{aligned} \lim_{i \rightarrow \infty} \|x_i - x^*\| &\leq \lim_{i \rightarrow \infty} [\|\Phi(x_{i-1}, F) - x^*\| + \|\xi_{i-1}\|] \\ &= \lim_{i \rightarrow \infty} \|\xi_{i-1}\| \leq \rho \|x^*\| (C \operatorname{cond}(F; d) + K) + O(\rho^2). \end{aligned}$$

2. Abstract Padé Approximants (APA) and Abstract Rational Approximants (ARA) for the Solution of a System of Nonlinear Equations. Let x_i be the i th approximant of the root x^* in the iterative process, $y_i = F(x_i)$ and the Newton-correction $a_i = -F_i'^{-1}F_i$. Using the Inversion Theorem [1, p. 381] we can see that

$$(3) \quad x^* = x_i + a_i - \frac{1}{2} F_i'^{-1} F_i'' a_i^2 + O(a_i^3),$$

where $F_i'' a_i^2$ is the bilinear operator F_i'' evaluated on (a_i, a_i) . The Newton-iteration results from approximating the series in (3) by its first two terms, i.e., the (1, 0)-APA [2].

In [7] Woźniakowski proves numerical stability of the Newton-iteration under a natural assumption on the computed evaluation of F .

THEOREM 2.1. *If*

(a) $\operatorname{fl}(F(x_i; d)) = (I + \Delta F_i)F(x_i + \Delta x_i; d + \Delta d_i) = F(x_i) + \delta F_i$, *with*

$$\delta F_i = \Delta F_i F(x_i) + F'_x(x_i) \Delta x_i + F'_d(x_i) \Delta d_i + O(\rho^2),$$

(b) $\operatorname{fl}(F'(x_i; d)) = F'(x_i) + \delta F'_i$, *with $\delta F'_i = O(\rho)$,*

(c) *the computed correction $\operatorname{fl}(a_i)$ is the exact solution of a perturbed linear system*

$$(F'(x_i) + \delta F'_i + E_i) \operatorname{fl}(a_i) = -F(x_i) - \delta F_i \quad \text{with } E_i = O(\rho),$$

then the Newton-iteration is numerically stable.

Proof. In [7].

Another way to approximate x^* is to use the (1, 1)-ARA [2] for the power series (3), i.e.

$$(4) \quad x_{i+1} = x_i + \frac{a_i^2}{a_i + \frac{1}{2} F_i'^{-1} F_i'' a_i^2},$$

where multiplication and division of the vectors in $\mathbb{R}^q$ in the numerator and denominator of (4) are componentwise. For $q = 1$ the iteration (4) is the well-known Halley-iteration. We will also use the name Halley-iteration for the case $q > 1$. We will now prove numerical stability of this iteration under assumptions similar to the assumptions for the Newton-iteration. We will also assume that the divisions in (4) are such that

$$(5) \quad \left(\frac{1}{a_i + \frac{1}{2} F_i'^{-1} F_i'' a_i^2} \right)^j O(\|a_i\|^{j-k} \rho^{k+l}) = O(\rho^l).$$

Condition (5) takes care of the fact that the denominator of the correction-term in (4) does not become too small in comparison with $O(\|a_i\|^{j-k}\rho^k)$.

The assumption of (5) is a natural generalization of the following relations:

$$(5a) \quad \begin{aligned} &\text{for } q = 1, \lim_{i \rightarrow \infty} \frac{a_i}{a_i + \frac{1}{2} F_i'^{-1} F_i'' a_i^2} = 1, \\ &\text{and so } \exists L \in \mathbb{N} \supset \forall i \geq L: \left| \frac{a_i}{a_i + \frac{1}{2} F_i'^{-1} F_i'' a_i^2} \right| < 1 + D \\ &\quad (\text{case } j = 1, k = 0, l = 0) \text{ with } D \in \mathbf{R}_0^+, \\ &\text{in a convergent process (4): } \lim_{i \rightarrow \infty} \|x^* - x_i\| = 0, \text{ and thus} \end{aligned}$$

$$(5b) \quad \begin{aligned} &\lim_{i \rightarrow \infty} a_i = 0, \text{ i.e. } \exists M \in \mathbb{N} \supset \forall i \geq M: a_i = O(\rho), \\ &\text{and so } \forall i \geq M: a_i^2 = O(\|a_i\|\rho); \text{ also} \\ &\lim_{i \rightarrow \infty} \frac{a_i^2}{a_i + \frac{1}{2} F_i'^{-1} F_i'' a_i^2} = 0, \text{ i.e.} \\ &\exists N \in \mathbb{N} \supset \forall i \geq N: \frac{a_i^2}{a_i + \frac{1}{2} F_i'^{-1} F_i'' a_i^2} = O(\rho), \\ &\text{and so } \forall i \geq \max(N, M): \frac{a_i^2}{a_i + \frac{1}{2} F_i'^{-1} F_i'' a_i^2} \\ &\quad = \frac{1}{a_i + \frac{1}{2} F_i'^{-1} F_i'' a_i^2} O(\|a_i\|\rho) \\ &\quad = O(\rho) \\ &\quad (\text{case } j = 1, k = 0, l = 1). \end{aligned}$$

THEOREM 2.2. *If*

$$(a) \text{ fl}(F(x_i; d)) = (I + \Delta F_i)F(x_i + \Delta x_i; d + \Delta d_i) = F(x_i) + \delta F_i \text{ with}$$

$$\delta F_i = \Delta F_i F(x_i) + F'_x(x_i) \Delta x_i + F'_d(x_i) \Delta d_i + O(\rho^2),$$

$$(b) \text{ fl}(F'(x_i; d)) = F'(x_i) + \delta F'_i \text{ with } \delta F'_i = O(\rho),$$

$$(c) \text{ fl}(F''(x_i; d)) = F''(x_i) + \delta F''_i \text{ with } \delta F''_i = O(\rho),$$

(d) *the computed correction fl(a_i) is the exact solution of a perturbed linear system*

$$(F'(x_i) + \delta F'_i + E_{i,1}) \text{fl}(a_i) = -F(x_i) - \delta F_i \text{ with } E_{i,1} = O(\rho),$$

(e) *analogously,*

$$(F'(x_i) + \delta F'_i + E_{i,2}) \text{fl}(b_i) = (F''(x_i) + \delta F''_i) \text{fl}(a_i)^2$$

$$\text{with } E_{i,2} = O(\rho) \text{ and } b_i = F_i'^{-1} F_i'' a_i^2,$$

and (5) holds, then the iteration (4) is numerically stable.

Proof. Let $F'(x_i) + \delta F'_i + E_{i,1} = F'(x_i)(I + H_{i,1})$, where

$$H_{i,1} = F'(x_i)^{-1} \{\delta F'_i + E_{i,1}\} = O(\rho)$$

because of (b) and (d). So for small ρ ,

$$(I + H_{i,1})^{-1} = I - H_{i,1} + O(\rho^2).$$

Thus

$$(6) \quad \text{fl}(a_i) = (I - H_{i,1})F_i'^{-1}(-F_i - \delta F_i).$$

Analogously

$$\text{fl}(b_i) = (I - H_{i,2})F_i'^{-1}(F_i'' + \delta F_i'')\text{fl}(a_i)^2 \quad \text{with } H_{i,2} = O(\rho).$$

Now

$$\begin{aligned} (F_i'' + \delta F_i'')\text{fl}(a_i)^2 &= (F_i'' + \delta F_i'')[(I - H_{i,1})F_i'^{-1}(-F_i - \delta F_i)]^2 \\ &= (F_i'' + \delta F_i'')a_i^2 + 2(F_i'' + \delta F_i'')(F_i'^{-1}F_i, F_i'^{-1}\delta F_i - H_{i,1}F_i'^{-1}F_i) + O(\rho^2) \\ &= (F_i'' + \delta F_i'')a_i^2 - 2F_i''(a_i, F_i'^{-1}\delta F_i - H_{i,1}F_i'^{-1}F_i) + O(\rho^2). \end{aligned}$$

Thus

$$\begin{aligned} \text{fl}(b_i) &= F_i'^{-1}(F_i'' + \delta F_i'')a_i^2 - 2F_i'^{-1}F_i''(a_i, F_i'^{-1}\delta F_i - H_{i,1}F_i'^{-1}F_i) \\ &\quad - H_{i,2}F_i'^{-1}F_i''a_i^2 + O(\rho^2). \end{aligned}$$

A computed approximation x_{i+1} satisfies

$$x_{i+1} = (I + \delta I_{i,1}) \left[x_i + (I + \delta I_{i,2}) \frac{\text{fl}(a_i)^2}{\text{fl}(a_i) + \frac{1}{2}\text{fl}(b_i)} \right],$$

where $\delta I_{i,1}$ and $\delta I_{i,2}$ are diagonal matrices and $\delta I_{i,1} = O(\rho)$ and $\delta I_{i,2} = O(\rho)$. So

$$x_{i+1} = (I + \delta I_{i,1}) \left[x_i + (I + \delta I_{i,2}) \frac{a_i^2 - 2a_i \cdot (F_i'^{-1}\delta F_i + H_{i,1}a_i) + O(\rho^2)}{a_i + \frac{1}{2}b_i - \delta a_i + O(\rho^2)} \right],$$

where

$$\begin{aligned} \delta a_i &= F_i'^{-1}\delta F_i + H_{i,1}a_i - \frac{1}{2}F_i'^{-1}\delta F_i''a_i^2 \\ &\quad + \frac{1}{2}H_{i,2}F_i'^{-1}F_i''a_i^2 + F_i'^{-1}F_i''(a_i, F_i'^{-1}\delta F_i - H_{i,1}F_i'^{-1}F_i). \end{aligned}$$

Using (6), we find

$$\text{fl}(a_i) - a_i + H_{i,1}a_i - H_{i,1}F_i'^{-1}\delta F_i = -F_i'^{-1}\delta F_i,$$

and thus, for positive constants D_1 and D_2 ,

$$\|F_i'^{-1}\delta F_i\| \leq D_2\rho\|a_i\| \quad \text{since } \|\text{fl}(a_i) - a_i\| \leq D_1\rho\|a_i\|$$

and

$$\|F_i'^{-1}\| \cdot \|F_i\| \leq \|F_i'^{-1}\| \cdot \|F_i'\| \cdot \|a_i\|.$$

Thus

$$x_{i+1} = (I + \delta I_{i,1}) \left[x_i + \frac{a_i^2 - 2a_i(F_i'^{-1}\delta F_i + H_{i,1}a_i) + \delta I_{i,2}a_i^2 + O(\rho^2\|a_i\|^2)}{a_i + \frac{1}{2}b_i - \delta a_i + O(\rho^2)} \right],$$

where $\delta I_{i,2}a_i^2$ is the linear operator $\delta I_{i,2}$ evaluated in a_i^2 (componentwise square of the vector a_i). So

$$x_{i+1} = (I + \delta I_{i,1}) \left[x_i + \frac{a_i^2 - 2a_i(F_i'^{-1}\delta F_i + H_{i,1}a_i) + \delta I_{i,2}a_i^2 + O(\rho^2\|a_i\|^2)}{a_i + \frac{1}{2}b_i} \cdot c_i \right],$$

with

$$c_i = 1 + \frac{1}{a_i + \frac{1}{2}b_i}(\delta a_i + O(\rho^2)) + \left(\frac{1}{a_i + \frac{1}{2}b_i} \right)^2 O(\|a_i\|^{2-k} \rho^{k+2}, k = 0, 1, 2)$$

since $\delta a_i = O(\rho\|a_i\|)$; in c_i we have used the notation $\mathbf{1}$ for the unit vector $(1, \dots, 1)$.

Using (5), we conclude

$$\left(\frac{1}{a_i + \frac{1}{2}b_i} \right)^2 O(\|a_i\|^{2-k} \rho^{k+2}, k = 0, 1, 2) = O(\rho^2).$$

For $\xi_i = x_{i+1} - \Phi(x_i, F)$, we have

$$\begin{aligned} \xi_i &= \delta I_{i,1} x_i + \frac{a_i^2}{a_i + \frac{1}{2}b_i} (c_i - 1) \\ &\quad + \frac{-2a_i(F_i'^{-1}\delta F_i + H_{i,1}a_i) + \delta I_{i,2}a_i^2 + O(\rho^2\|a_i\|^2)}{a_i + \frac{1}{2}b_i} \cdot c_i \\ &\quad + \delta I_{i,1} \frac{a_i^2}{a_i + \frac{1}{2}b_i} \cdot c_i + O(\rho^2). \end{aligned}$$

So

$$\begin{aligned} \xi_i &= \delta I_{i,1} x_i + \left(\frac{1}{a_i + \frac{1}{2}b_i} \right)^2 O(\rho\|a_i\|^3, \rho^2\|a_i\|^2) + \frac{1}{a_i + \frac{1}{2}b_i} O(\rho^2\|a_i\|^2) \\ &\quad + \frac{1}{a_i + \frac{1}{2}b_i} (-2a_i F_i'^{-1}\delta F_i + O(\rho\|a_i\|^2, \rho^2\|a_i\|^2)) \cdot (1 + O(\rho)) \\ &\quad + O(\rho^2). \end{aligned}$$

Thus

$$\|\xi_i\| \leq k_1 \rho \|x_i\| + k_2 \rho \|a_i\| + \left\| \frac{-2a_i}{a_i + \frac{1}{2}b_i} F_i'^{-1}\delta F_i \right\| + O(\rho^2),$$

and since

$$\begin{aligned} \frac{-2a_i}{a_i + \frac{1}{2}b_i} F_i'^{-1}\delta F_i &= \frac{-2a_i}{a_i + \frac{1}{2}b_i} F_i'^{-1}(\Delta F_i F(x_i) + F_i' \Delta x_i + F_d' \Delta d_i + O(\rho^2)) \\ &= \frac{1}{a_i + \frac{1}{2}b_i} O(\rho\|a_i\|) F(x_i) - \frac{2a_i}{a_i + \frac{1}{2}b_i} \Delta x_i \\ &\quad - \frac{2a_i}{a_i + \frac{1}{2}b_i} F_i'^{-1} F_d' \Delta d_i + \frac{1}{a_i + \frac{1}{2}b_i} O(\rho^2\|a_i\|), \end{aligned}$$

we find that

$$\lim_{i \rightarrow \infty} \|\xi_i\| \leq \rho \|x^*\| (K + C \operatorname{cond}(F; d)) + O(\rho^2)$$

for $\lim_{i \rightarrow \infty} a_i = 0 = \lim_{i \rightarrow \infty} F(x_i)$ in a convergent process and $a_i \Delta x_i = O(\rho\|a_i\|)$ and $a_i F_i'^{-1} F_d' \Delta d_i = O(\rho\|a_i\|)$.

3. Numerical Example. Consider the following operator:

$$F: \mathbf{R}^2 \rightarrow \mathbf{R}^2: (x, y) \rightarrow \begin{pmatrix} e^{-x+y} - d_1 \\ e^{-x-y} - d_2 \end{pmatrix} \quad \text{with } d_1 > 0 \text{ and } d_2 > 0.$$

The operator F has a simple root $x^* = (-\frac{1}{2} \ln(d_1 d_2), \frac{1}{2} \ln(d_1/d_2))$. Clearly

$$d = (d_1, d_2)$$

is the data vector. Now

$$\text{fl}(F(x, y; d)) = \begin{pmatrix} [(1 + \varepsilon_1)e^{(-x - \Delta'x + y + \Delta'y)(1 + \theta_1)} - (d_1 + \Delta'_1 d)](1 + \kappa_1) \\ [(1 + \varepsilon_2)e^{(-x - \Delta'x - y - \Delta'y)(1 + \theta_2)} - (d_2 + \Delta'_2 d)](1 + \kappa_2) \end{pmatrix},$$

where $\text{fl}(x) = x + \Delta'x$, $\text{fl}(y) = y + \Delta'y$, $\text{fl}(d_1) = d_1 + \Delta'_1 d$, $\text{fl}(d_2) = d_2 + \Delta'_2 d$, θ_1 is caused by $-\text{fl}(x) + \text{fl}(y)$, θ_2 is caused by $-\text{fl}(x) - \text{fl}(y)$, ε_i are caused by the exponential evaluations ($i = 1, 2$), κ_i are caused by the subtraction of $\text{fl}(d_i)$ ($i = 1, 2$).

One can rewrite $\text{fl}(F(x, y; d)) = (I + \Delta F)F(x + \Delta x, y + \Delta y; d + \Delta d)$ with

$$\Delta x = x\theta_1 + \Delta'x(1 + \theta_1), \quad \Delta y = y\theta_1 + \Delta'y(1 + \theta_1), \quad \Delta d = (\Delta_1 d, \Delta_2 d),$$

$$\Delta_1 d = \frac{\Delta'_1 d - \varepsilon_1 d_1}{1 + \varepsilon_1},$$

$$\Delta_2 d = \frac{\Delta'_2 d - \varepsilon_2 d_2}{1 + \varepsilon_2} + \frac{d_2 + \Delta'_2 d}{1 + \varepsilon_2} (e^{(x + \Delta'x + y + \Delta'y)(\theta_2 - \theta_1)} - 1),$$

$$\Delta F = \begin{pmatrix} (1 + \varepsilon_1)(1 + \kappa_1) - 1 & 0 \\ 0 & (1 + \varepsilon_2)(1 + \kappa_2)e^{(x + \Delta'x + y + \Delta'y)(\theta_1 - \theta_2)} - 1 \end{pmatrix}.$$

The inverse of the Jacobian matrix in the root x^* is

$$\frac{1}{2(d_1 \cdot d_2)} \begin{pmatrix} -d_2 & -d_1 \\ d_2 & -d_1 \end{pmatrix} \quad \text{and} \quad F'_d = \begin{pmatrix} -1 & 0 \\ 0 & -1 \end{pmatrix}.$$

The condition number of F with respect to the data vector d is

$$\|F'_x(x^*; d)^{-1}\| \cdot \frac{\|(d_1, d_2)\|}{\|x^*\|}.$$

Using the Schur-norm $\|A\| = \sqrt{\sum_{i,j} a_{ij}^2}$ of a matrix $A = (a_{ij})$ and the l_2 -norm $\|a\| = \sqrt{\sum_i a_i^2}$ of a vector $a = (a_i)$, the condition number is

$$\frac{d_1^2 + d_2^2}{\sqrt{2} d_1 \cdot d_2 \cdot \|x^*\|}.$$

Putting $d_1 = d = d_2$, the root $x^* = (-\ln d, 0)$ and the condition number is $\sqrt{2}/|\ln d|$. The problem is extremely well-conditioned if $\text{cond}(F; d) \leq 1$, i.e.,

$$d \in]-\infty, e^{-\sqrt{2}}] \cup [e^{\sqrt{2}}, +\infty[.$$

The problem is very ill-conditioned if $d = e^\varepsilon$ with ε very small. We will now check some of the conditions of Theorem 2.2. We already know $\text{fl}(F(x, y; d)) = (I + \Delta F)F(x + \Delta x, y + \Delta y; d + \Delta d)$.

Now

$$\text{fl}(F'(x, y; d)) = \text{fl} \begin{pmatrix} -e^{-x+y} & e^{-x+y} \\ -e^{-x-y} & -e^{-x-y} \end{pmatrix},$$

where

$$\begin{aligned} \text{fl}(e^{-x+y}) &= (1 + \varepsilon_1)e^{(-x-\Delta'x+y+\Delta'y)(1+\theta_1)} = (1 + \varepsilon_1)e^{-x+y}e^{-\Delta x+\Delta y} \\ &= e^{-x+y} [1 + \varepsilon_1 + (1 + \varepsilon_1)(e^{-\Delta x+\Delta y} - 1)], \\ \text{fl}(e^{-x-y}) &= (1 + \varepsilon_2)e^{(-x-\Delta'x-y-\Delta'y)(1+\theta_2)} \\ &= (1 + \varepsilon_2)e^{-x-y}e^{-\Delta x-\Delta y}e^{(x+\Delta'x+y+\Delta'y)(\theta_1-\theta_2)} \\ &= e^{-x-y} [1 + \varepsilon_2 + (1 + \varepsilon_2)(e^{-\Delta x-\Delta y}e^{(x+\Delta'x+y+\Delta'y)(\theta_1-\theta_2)} - 1)]. \end{aligned}$$

So $\text{fl}(F'(x, y; d)) = F'(x, y; d) + \delta F'(x, y; d)$ with

$$\begin{aligned} \delta F'(x, y; d) &= \begin{pmatrix} \varepsilon_1 + (1 + \varepsilon_1)(e^{-\Delta x+\Delta y} - 1) & 0 \\ 0 & \varepsilon_2 + (1 + \varepsilon_2)(e^{-\Delta x-\Delta y}e^{(x+\Delta'x+y+\Delta'y)(\theta_1-\theta_2)} - 1) \end{pmatrix} \\ &\cdot F'(x, y; d) = O(\rho). \end{aligned}$$

We can write down an analogous formula for $F''(x, y; d)$.

We remark that the algorithm even behaves considerably well for a condition number of the order of 10^3 or 10^4 .

The two linear systems of equations are well-conditioned since the condition number of the linear systems in $x^* = \lim_{i \rightarrow \infty} x_i$ is

$$\|F'_x(x^*; d)^{-1}\| \cdot \|F'_x(x^*; d)\| = 2.$$

One can prove that the use of Gaussian elimination with row pivoting for this example satisfies the conditions (d) and (e) of Theorem 2.2. So we can expect to get a reasonable approximation of the solution of $F(x, y; d) = 0$ using the numerically stable iterative method (4); the numerical results illustrate this. Let us at the same time follow the loss of significant digits in the root x^* as the problem becomes worse-conditioned. The calculations are performed in double precision ($t = 56$) on the PDP 11/45 of the University of Antwerp. We will solve the nonlinear system

$F(x, y; d) = 0$ for $d = e^{10^{-k}}$, $k = 0, \dots, 16$. The root $x^* = (-10^{-k}, 0)$. For each d we give the 6th iteration-step (x_6, y_6) in the procedure (4) starting from $(x_0, y_0) = (2, 2)$, the number l of significant digits in x_6 , and the condition number $\text{cond}(F; e^{10^{-k}})$. It is also important to know that the iterative procedure stops at the 6th iteration-step, except for $k = 7, 13$, and 14 where, respectively, $l = 11, 5$, and 3 in the last iteration-step (x_7, y_7) . We have used the stop-criterion

$$\max(|x_{i+1} - x_i|, |y_{i+1} - y_i|) \leq 10^{-15} \max(|x_{i+1}|, |y_{i+1}|).$$
