Convex Interpolation by Splines of Arbitrary Degree

By Holger Mettke

Abstract. An algorithm is described for computing an interpolation spline of arbitrary but fixed degree which preserves the convexity of the given data set. Necessary and sufficient conditions for the solvability of the problem, some special cases and error estimations are given.

1. Introduction. In some problems arising from science or engineering the solution of an interpolation problem with constraints is required. For example, if a convex data set is given then the interpolant should also be convex. Using standard techniques like polynomial or cubic spline interpolation the resulting interpolant is not convex in general (see [5]).

In recent years convex interpolation by splines has been investigated in several publications (see [3]–[17]). Various possibilities were proposed to assure the convexity of an interpolation spline. They reach from additional conditions on the data set to additional knots of the interpolation spline.

In this paper we consider convex interpolation by splines of arbitrary degree $k \geq 3$ with smoothness q , where $1 \leq q \leq [(k-1)/2]$. As is known, the solvability of such an interpolation problem is equivalent to that of a special system of linear inequalities. Necessary and sufficient conditions are derived such that this system has a solution, and an algorithm is described to find all solutions of the system of inequalities. Furthermore, a sufficient condition is given which always assures the solvability of the system and which is easy to test. In this case, a solution can be found even with a reduced algorithm. The sufficient condition just mentioned is interpreted in different ways. Specifically, for a strictly convex data set it is possible to give a lower bound for the degree k such that the interpolation problem is solvable. For the developed method no additional spline knots are needed. In the last section, the important question of error estimation is investigated. Under certain assumptions, error bounds are derived for continuous and continuously differentiable underlying functions. The assumptions are related to the solvability of the convex interpolation problem, and in one case to the ratio of contiguous step sizes of the grid. In the differentiable case, the order of approximation is better than in the continuous one.

2. Definitions and Notation. Let π be an arbitrary but fixed partition of the interval $[a, b]$, i.e.,

$$\pi: a = x_0 < x_1 < \cdots < x_{n-1} < x_n = b \quad (n > 0).$$

The maximal mesh length is abbreviated as

$$h = \max_{1 \leq i \leq n} h_i \quad \text{where } h_i = x_i - x_{i-1}.$$

Further, for given integers k, q with $0 \leq q \leq k-1$ we denote by $S(k, q, \pi)$ the space of all polynomial splines of degree k associated with π with deficiency at most $(k-q)$ at the knots. That is, $s \in S(k, q, \pi)$ if and only if $s \in C^q[a, b]$ and in each subinterval $[x_{i-1}, x_i]$ s coincides with a polynomial of degree k .

Let f_i ($i = 0, 1, \dots, n$) be given real numbers. Then the data set $\{(x_i, f_i), i = 0, 1, \dots, n\}$ is said to be *convex* if and only if, with the abbreviation $\tau_i = (f_i - f_{i-1})/h_i$, the inequalities

$$\tau_1 \leq \tau_2 \leq \dots \leq \tau_{n-1} \leq \tau_n$$

are valid (see [14], [15]). The data set is called *strictly convex* if and only if the inequalities $\tau_1 < \tau_2 < \dots < \tau_{n-1} < \tau_n$ hold. Our aim is to investigate the following interpolation problem (I).

(I) For a given convex data set $\{(x_i, f_i), i = 0, 1, \dots, n\}$ find a spline $s \in S(k, q, \pi)$ satisfying the conditions

$$(2.1) \quad s(x_i) = f_i \quad (i = 0, 1, \dots, n)$$

and

$$(2.2) \quad s \text{ is convex on } [a, b].$$

In this paper we restrict our attention to the case when $k \geq 3$ and $1 \leq q \leq [(k-1)/2]$ where, as usual, $[r]$ denotes the greatest integer not greater than r .

In order to construct solutions of (I), some special fundamental polynomials are used. They are defined in the following manner (see [12] and for special cases [1], [13], [18]): Let u_i ($i = 1, 2, \dots, n$) be given integers such that $1 < u_i < k$ and $\min_{1 \leq j \leq n-1} r_j = q$, where $r_j = \min\{u_j - 1, k - u_{j+1}\}$. Then the functions

$$\begin{aligned} \varphi_{1,i}(t) &= a_{k,u_i} \cdot \int_0^t \xi^{k-u_i} (1-\xi)^{u_i-1} d\xi, \\ \varphi_{0,i}(t) &= 1 - \varphi_{1,i}(t), \\ \varphi_{2,i}(t) &= t \cdot \left[1 - a_{k-1,u_i} \cdot \int_0^t \xi^{k-u_i-1} (1-\xi)^{u_i-1} d\xi \right], \\ \varphi_{3,i}(t) &= a_{k-1,u_i-1} (1-t) \cdot \int_0^t \xi^{k-u_i} (1-\xi)^{u_i-2} d\xi \end{aligned}$$

($i = 1, 2, \dots, n$), defined on $[0, 1]$ are the *fundamental polynomials*. Here, the abbreviation $a_{\mu,\nu}$ means

$$(2.3) \quad a_{\mu,\nu} = \binom{\mu}{\nu} = \left[\int_0^1 \xi^{\mu-\nu} (1-\xi)^{\nu-1} d\xi \right]^{-1}.$$

For the reader's convenience we recall some properties of these functions:

- (i) $\varphi_{0,i}, \dots, \varphi_{3,i}$ are polynomials of degree k .
- (ii) $\varphi_{j,i}: [0, 1] \rightarrow [0, 1]$, $j = 0, 1, 2, 3$.
- (iii) $\varphi_{j,i}$ is determined by the following fundamental properties:

$$\begin{aligned} \varphi_{j,i}^{(\nu)}(0) &= \delta_{j,0} \delta_{\nu,0}, & \varphi_{j+2,i}^{(\nu)}(0) &= \delta_{j,0} \delta_{\nu,1} & (j = 0, 1; \nu = 0, \dots, k - u_i), \\ \varphi_{j,i}^{(\nu)}(1) &= \delta_{j,1} \delta_{\nu,0}, & \varphi_{j+2,i}^{(\nu)}(1) &= (-1)^j \delta_{j,1} \delta_{\nu,1} & (j = 0, 1; \nu = 0, \dots, u_i - 1). \end{aligned}$$

Thus, the above polynomials are special Hermite interpolation polynomials. We define

$$(2.4) \quad p_i(x) = f_{i-1}\varphi_{0,i}(t) + f_i\varphi_{1,i}(t) + h_i[m_{i-1}\varphi_{2,i}(t) - m_i\varphi_{3,i}(t)]$$

($x \in [x_{i-1}, x_i]$), with the abbreviation

$$t = \frac{x - x_{i-1}}{h_i},$$

which is used from here on throughout the paper. The quantities $m_i = p'_i(x_i) = p'_{i+1}(x_i)$ are free parameters. Then the function $s: [a, b] \rightarrow R$, given by

$$(2.5) \quad s(x) = p_i(x) \quad (x \in [x_{i-1}, x_i]),$$

is a spline from $S(k, q, \pi)$. Moreover, for every choice of parameters m_i the spline s solves the interpolation problem (2.1). We note that in particular $s \in C^r$ in a neighborhood of x_i . Hence the deficiency of s at the knot x_i can be controlled with the help of u_i, u_{i+1} .

3. Convex Interpolation. In general, for a convex data set an interpolating spline of the form (2.4), (2.5) is not convex. There arises the question if there exist parameters m_i such that the corresponding interpolating spline s is also a solution of (2.2). A partial answer to this question is given by the following theorem (see [12]).

THEOREM 3.1. *Let $\{(x_i, f_i), i = 0, \dots, n\}$ be a convex data set. Then an interpolating spline s of the form (2.4), (2.5) is convex on the interval $[a, b]$ if and only if the parameters $m_0, m_1, \dots, m_n$ solve the linear system of inequalities*

$$(3.1) \quad \begin{aligned} (k - u_i + 1)m_{i-1} + (u_i - 1)m_i &\leq k\tau_i \\ (k - u_i)m_{i-1} + u_i \cdot m_i &\geq k\tau_i \end{aligned} \quad (i = 1, 2, \dots, n).$$

If we can find a solution of (3.1) then, by (2.4), (2.5), a solution of (I) is given. On the other hand, there exist convex (even strictly convex) data sets for which the system (3.1) is unsolvable. This is a consequence of the following theorem, given by Passow and Roulier [15]:

THEOREM 3.2. *For any integer $k \geq 1$ there exists a set of five data points $\{(x_i, f_i), i = 0, \dots, 4\}$ with $\tau_1 < \tau_2 < \tau_3 < \tau_4$, for which no spline $s \in S(k, 1, \tilde{\pi})$, $\tilde{\pi}: x_0 < x_1 < x_2 < x_3 < x_4$ satisfies $s(x_i) = f_i$ ($i = 0, \dots, 4$) with s convex on $[x_0, x_4]$.*

4. An Algorithm. In this section we present an algorithm for solving (3.1). Moreover, necessary and sufficient conditions for the solvability of this system are derived. In [6] the author described an algorithm for solving (3.1) in the case $k = 3$. The extension of the method to the general system (3.1) was realized in an unpublished paper. Starting from this, Schmidt and Hess [17] developed a more effective variant. The algorithm given here is the symmetric variant of it. For simplification, in view of (3.1), we use the following abbreviations:

$$\alpha_i = (k - u_i + 1)/k, \quad \beta_i = (u_i - 1)/k, \quad \gamma_i = (k - u_i)/k, \quad \delta_i = u_i/k.$$

ALGORITHM

Step 1 (Backward-step):

Put $A_n = \tau_n$ and $B_n = (\tau_n - \alpha_n \tau_{n-1})/\beta_n$

For $i = n, n-1, \dots, 1$ do

 If $\tau_i > B_i$ then stop else

 put $A_{i-1} = (\tau_i - \delta_i B_i)/\gamma_i$ and $B_{i-1} = \min\{\tau_i, (\tau_i - \beta_i A_i)/\alpha_i\}$

Step 2 (Forward-step):

Choose $m_0 \in [\underline{m}_0, \bar{m}_0]$ with $\underline{m}_0 = A_0$ and $\bar{m}_0 = B_0$.

For $i = 1, 2, \dots, n$ do

 Choose $m_i \in [\underline{m}_i, \bar{m}_i]$ with

$\underline{m}_i = \max\{A_i, (\tau_i - \gamma_i m_{i-1})/\delta_i\}$ and

$\bar{m}_i = \min\{B_i, (\tau_i - \alpha_i m_{i-1})/\beta_i\}$.

Before we make some remarks on the Algorithm let us formulate the following result, which can be proved by considerations analogous to those in [17].

THEOREM 4.1. *Let the data set $\{(x_i, f_i), i = 0, 1, \dots, n\}$ be convex. Then the following statements are equivalent:*

- (i) *The system of inequalities (3.1) is solvable.*
- (ii) *The Algorithm is well-defined and yields a solution of (3.1).*
- (iii) *The inequalities $\tau_i \leq B_i$ are valid for $i = 1, 2, \dots, n$.*

Remarks. 1. The above Algorithm makes strong use of the special structure of the system (3.1).

2. The Algorithm is of a global nature in the sense that a change of data points or an extension of the data set has influence on all intervals of admissible parameters in general.

3. The fact that we have a whole interval $[\underline{m}_i, \bar{m}_i]$ of admissible parameters m_i can be used to look for “visually pleasant” convex spline interpolants (see [2]).

4. It is easy to show that with the help of the Algorithm all solutions of (3.1) can be found.

5. The statement (iii) in Theorem 4.1 can be replaced by “(iii’) The inequalities $\tau_i \leq B_i$ are valid for $i = 1, 2, \dots, n-3$.” This is possible because the remaining inequalities always hold.

5. Special Cases. The first special case is embodied in the following theorem.

THEOREM 5.1. *Let the convex data set $\{(x_i, f_i), i = 0, 1, \dots, n\}$ be given such that*

$$(5.1) \quad \frac{u_{j+1}}{k - u_{j+1}} \cdot (\tau_{j+2} - \tau_{j+1}) - (\tau_{j+1} - \tau_j) \geq 0, \quad j = 1, 2, \dots, n-2.$$

Then there exists a solution of (3.1) and, consequently, the interpolation problem (I) possesses a solution.

Proof. Because of Theorem 4.1 it is sufficient to verify that $\tau_i \leq B_i$ ($i = 1, 2, \dots, n-3$). This follows from the next lemma, which completes the proof. Q.E.D.

LEMMA 5.2. *With the assumption of Theorem 5.1 we have*

$$(5.2) \quad B_{i-1} = \tau_i, \quad i = 1, 2, \dots, n.$$

Proof. For $i = n, n - 1$ the relation (5.2) is valid. Let us suppose that (5.2) holds for $i = n, n - 1, \dots, j + 1$. Then $B_j \geq \tau_j$ and A_{j-1}, B_{j-1} are well-defined. Because of

$$A_j = \frac{\tau_{j+1} - \delta_{j+1}B_{j+1}}{\gamma_{j+1}} = \frac{\tau_{j+1} - \delta_{j+1}\tau_{j+2}}{\gamma_{j+1}},$$

we obtain, with (5.1), that

$$\begin{aligned} \frac{\tau_j - \beta_j A_j}{\alpha_j} - \tau_j &= \frac{\beta_j}{\alpha_j} (\tau_j - A_j) \\ &= \frac{\beta_j}{\alpha_j} \left\{ \frac{\delta_{j+1}}{\gamma_{j+1}} (\tau_{j+2} - \tau_{j+1}) - (\tau_{j+1} - \tau_j) \right\} \geq 0. \end{aligned}$$

Thus $B_{j-1} = \tau_j$. Q.E.D.

In the case of (5.1) the backward-step of the Algorithm can be omitted and we get a

REDUCED ALGORITHM.

For $i = 1, 2, \dots, n$ choose $m_i \in [\underline{m}_i, \bar{m}_i]$ with

$$\begin{aligned} \underline{m}_0 &= \frac{\tau_1 - \delta_1 \tau_2}{\gamma_1}, \quad \bar{m}_0 = \tau_1 \\ \underline{m}_j &= \max \left\{ \frac{\tau_{j+1} - \delta_{j+1} \tau_{j+2}}{\gamma_{j+1}}, \frac{\tau_j - \gamma_j m_{j-1}}{\delta_j} \right\} \\ \bar{m}_j &= \min \left\{ \tau_{j+1}, \frac{\tau_j - \alpha_j m_{j-1}}{\beta_j} \right\} \\ \underline{m}_{n-1} &= \frac{\tau_{n-1} - \gamma_{n-1} m_{n-1}}{\delta_{n-1}} \\ \bar{m}_{n-1} &= \min \left\{ \tau_n, \frac{\tau_{n-1} - \alpha_{n-1} m_{n-2}}{\beta_{n-1}} \right\} \\ \underline{m}_n &= \frac{\tau_n - \gamma_n m_{n-1}}{\delta_n}, \quad \bar{m}_n = \frac{\tau_n - \alpha_n m_{n-1}}{\beta_n}. \end{aligned} \quad (j = 1, 2, \dots, n-2)$$

Remark. If we put $k = 3$ and, hence, $u_i = 2$ ($i = 1, 2, \dots, n$) the above Reduced Algorithm is equivalent to Algorithm 2 presented in [6]. From Theorem 5.1 we can derive some interesting conclusions. We first assume that the degree k is fixed and the smoothness q , $q \geq 1$, is not of importance, i.e., the parameters u_i can be chosen arbitrarily between 1 and k . Then we get

COROLLARY 5.3. *Let the given data set be strictly convex. If parameters u_i , ($i = 2, 3, \dots, n-1$), can be found with*

$$(5.3) \quad \frac{k(\tau_{j+1} - \tau_j)}{\tau_{j+2} - \tau_j} \leq u_{j+1} < k \quad (j = 1, 2, \dots, n-2),$$

then the interpolation problem (I) possesses a solution.

This fact is clear because the left-hand inequality of (5.3) is equivalent to (5.1). The remaining quantities, namely u_1 and u_n , have no influence on the result of Corollary 5.3. Therefore, they can be chosen arbitrarily with $1 < u_1, u_n < k$.

If for fixed k the problem (I) has no solution then there arises the question: Does there exist a solution of (I) for splines of degree larger than k ? An answer to this question was given implicitly in [5]. We obtain a positive answer with the help of (5.3) in the form of a lower bound for k . Namely, if for given $q \in \{1, 2, \dots, [(k-1)/2]\}$

$$(5.4) \quad \frac{k(\tau_{j+1} - \tau_j)}{\tau_{j+2} - \tau_j} \leq k - q \quad (j = 1, 2, \dots, n-2),$$

then we could take $u_{j+1} = k - q$ ($j = 1, 2, \dots, n-2$) as admissible values and, hence, a q -times continuously differentiable solution of (I) is guaranteed. From (5.4) we obtain (see also [17]):

COROLLARY 5.4. *Let the given data set be strictly convex. If the degree k of used splines is chosen such that*

$$(5.5) \quad k \geq q \cdot \max_{1 \leq j \leq n-2} \frac{\tau_{j+2} - \tau_j}{\tau_{j+2} - \tau_{j+1}},$$

then there exists a solution of (I) in $S(k, q, \pi)$.

Obviously, under the assumptions of Corollary 5.3 resp. 5.4, corresponding solutions can be found with the help of the Reduced Algorithm. Corollary 5.4 is an alternative to the negative result of Theorem 3.2 of Passow and Roulier [15], given there for fixed k . Finally, we point out the fact that under assumption (5.1) a solution of (3.1) can be obtained by solving a first-order linear difference equation.

COROLLARY 5.5. *For a given convex data set let (5.1) be valid. Then the solution of*

$$(5.6) \quad \gamma_i m_{i-1} + \delta_i m_i = \tau_i \quad (i = 1, 2, \dots, n)$$

with $m_0 = (\tau_1 - \delta_1 \tau_2)/\gamma_2$ is also a solution of (3.1).

Proof. In view of (3.1) we have only to verify that the solution of (5.6) fulfills the inequalities

$$\alpha_i m_{i-1} + \beta_i m_i \leq \tau_i \quad (i = 1, 2, \dots, n).$$

From (5.6) we obtain after easy calculations

$$\alpha_i m_{i-1} + \beta_i m_i = \tau_i + \frac{1}{k\gamma_i} (\tau_i - m_i).$$

Thus we have to show that $\tau_i - m_i \leq 0$ ($i = 1, 2, \dots, n$). We prove this by induction. For $i = 1, 2$ the relation is obviously fulfilled. For $j \geq 3$ we get

$$\begin{aligned} \tau_j - m_j &= \tau_j - \frac{\tau_j - \gamma_j m_{j-1}}{\delta_j} = \frac{\gamma_j}{\delta_j \delta_{j-1}} \{ \tau_{j-1} - \delta_{j-1} \tau_j - \gamma_{j-2} m_{j-2} \} \\ &\leq \frac{\gamma_j}{\delta_j \delta_{j-1}} \{ \tau_{j-1} - \delta_{j-1} \tau_j - \gamma_{j-1} \tau_{j-2} \} \leq 0, \end{aligned}$$

because of (5.1). Q.E.D.

The second special case deals with monotone increasing and convex spline interpolation. Given a monotone increasing and convex data set, i.e., $0 \leq \tau_1 \leq \tau_2 \leq \dots \leq \tau_n$, then we obtain with the Algorithm nonnegative solutions of (3.1) if the conditions (iii) of Theorem 4.1 and $B_0 \geq 0$ hold and if in Step 2 of the Algorithm,

$\underline{m}_0$ is substituted by

$$\underline{m}_0 = \max\{A_0, 0\}.$$

If even (5.1) is valid, then the Reduced Algorithm always produces a nonnegative solution by substituting $\underline{m}_0$ by

$$\underline{m}_0 = \max\left\{\frac{\tau_1 - \delta_1 \tau_2}{\gamma_1}, 0\right\}.$$

Thus we obtain a monotone increasing and convex solution of (I).

6. Error Estimation. Let $f \in C[a, b]$ be a given function and let $f_i = f(x_i)$ ($i = 0, 1, \dots, n$). We denote by $\|f\|$ the maximum norm and by $\omega(f, \delta)$ the modulus of continuity of f on the interval $[a, b]$. Further, let

$$\tilde{q} = \min\{k - u_1, q, u_n - 1\}.$$

THEOREM 6.1. *Let $f \in C^1[a, b]$ be given such that for the considered data set the system (3.1) is solvable. Then the error between f and an interpolation spline s of the form (2.4), (2.5) can be estimated by*

$$(6.1) \quad \|f^{(\nu)} - s^{(\nu)}\| \leq D_\nu \omega(f', h) \cdot h^{1-\nu} \quad \text{for } \nu = 0, 1,$$

where

$$2 \cdot D_0 = D_1 = \frac{4k - \tilde{q}}{\tilde{q}} + \frac{4k(k - 2)}{\tilde{q}(\tilde{q} + 1)}.$$

Proof. With the defining equations of $\varphi_{j,i}$ we first obtain

$$s'(x) = m_{i-1} + a_{k,u_i} \cdot \int_0^t \xi^{k-u_i-1} (1-\xi)^{u_i-2} \{\lambda_i \xi + \rho_i\} d\xi, \quad x \in [x_{i-1}, x_i],$$

where

$$(6.2) \quad \lambda_i = (k - u_i)m_{i-1} + (u_i - 1)m_i - (k - 1)\tau_i,$$

$$(6.3) \quad \rho_i = \frac{k - u_i}{k} \{k\tau_i - (k - u_i + 1)m_{i-1} - (u_i - 1)m_i\}.$$

From the inequalities

$$\frac{k\tau_i - (k - u_i)m_{i-1}}{u_i} \leq m_i \leq \frac{k\tau_i - (k - u_i + 1)m_{i-1}}{u_i - 1}$$

it is easy to verify that

$$(6.4) \quad \frac{k - u_i}{u_i} (m_{i-1} - \tau_i) \leq \lambda_i \leq \tau_i - m_{i-1},$$

$$(6.5) \quad 0 \leq \rho_i \leq \frac{k - u_i}{u_i} (\tau_i - m_{i-1}).$$

Therefore, in view of $m_{i-1} \leq \tau_i \leq m_i$, we get after some calculations

$$|s'(x) - f'(x)| \leq |m_{i-1} - f'(x)| + \frac{k}{u_i - 1} \cdot |\lambda_i| + \frac{k(k - 1)}{(u_i - 1)(k - u_i)} \rho_i.$$

An analysis of $|\lambda_i|$ leads to

$$|s'(x) - f'(x)| \leq |m_{i-1} - f'(x)| + \frac{2k(k - u_i)}{u_i(u_i - 1)} \cdot (\tau_i - m_{i-1}) + (m_i - m_{i-1}).$$

Now, because of

$$(6.6) \quad \frac{k\tau_1 - u_1\tau_2}{k - u_1} \leq m_0 \leq \tau_1, \quad \tau_n \leq m_n \leq \frac{k\tau_n - (k - u_n + 1)\tau_{n-1}}{u_n - 1},$$

and $m_{i-1} \leq \tau_i \leq m_i$ ($i = 1, 2, \dots, n$), the following estimates are valid:

$$|m_{i-1} - f'(x)| \leq \begin{cases} \frac{u_1}{k - u_1}(\tau_2 - \tau_1) + |\tau_1 - f'(x)| \leq \frac{k + u_1}{k - u_1} \cdot \omega(f', h) & \text{if } i = 1, \\ |\tau_{i-1} - f'(x)| \leq 2 \cdot \omega(f', h) & \text{if } i \in \{2, 3, \dots, n\}, \end{cases}$$

$$\tau_i - m_{i-1} \leq \begin{cases} \frac{u_1}{k - u_1}(\tau_2 - \tau_1) \leq 2 \cdot \frac{u_1}{k - u_1} \cdot \omega(f', h) & \text{if } i = 1, \\ (\tau_i - \tau_{i-1}) \leq 2 \cdot \omega(f', h) & \text{if } i \in \{2, 3, \dots, n\}, \end{cases}$$

$$m_i - m_{i-1} \leq \begin{cases} \tau_2 - \frac{k\tau_1 - u_1\tau_2}{k - u_1} \leq \frac{2k}{k - u_1} \omega(f', h) & \text{if } i = 1, \\ \tau_{i+1} - \tau_{i-1} \leq 3 \cdot \omega(f', h) & \text{if } i \in \{2, 3, \dots, n-1\}, \\ \frac{k\tau_n - (k - u_n + 1)\tau_{n-1}}{u_n - 1} - \tau_{n-1} \leq \frac{2k}{u_n - 1} \cdot \omega(f', h) & \text{if } i = n. \end{cases}$$

Finally, the bounds

$$\max\left\{\frac{k + u_1}{k - u_1}, 2\right\} \leq \frac{2k - \tilde{q}}{\tilde{q}}, \quad \max\left\{\frac{2k}{k - u_1}, 3, \frac{2k}{u_n - 1}\right\} \leq \frac{2k}{\tilde{q}},$$

$$\max\left\{\frac{4k}{u_1 - 1}, \frac{4k(k - u_i)}{u_i(u_i - 1)}, (i = 2, 3, \dots, n)\right\} \leq \frac{4k(k - 2)}{\tilde{q}(\tilde{q} + 1)}$$

give (6.1) for $\nu = 1$. The estimate (6.1) for $\nu = 0$ can be obtained from this by standard techniques. Q.E.D.

THEOREM 6.2. *Let $f \in C[a, b]$ be given such that for the considered data set the system (3.1) is solvable. With the abbreviation*

$$\Omega(\pi) = \max\{h_i/h_j, |i - j| = 1\}$$

we obtain for a convex interpolation spline of the form (2.4), (2.5) the estimate

$$(6.7) \quad \|f - s\| \leq C_0 \cdot \omega(f, h)$$

with $C_0 = 2\{k + (k - \tilde{q})\Omega(\pi)/\tilde{q}\} + 1$.

Proof. By virtue of (2.4), (2.5) we get

$$|s(x) - f(x)| \leq |f_{i-1} - f(x)| + |m_{i-1}|h_i + |m_i|h_i, \quad x \in [x_{i-1}, x_i].$$

Further, from (6.6) there follows

$$|m_{i-1}|h_i \leq \begin{cases} \max\left\{|\tau_1|, \frac{|k\tau_1 - u_1\tau_2|}{k - u_1}\right\}h_1 \leq \left(k + \frac{u_1}{k - u_1} \cdot \frac{h_1}{h_2}\right) \cdot \omega(f, h) & \text{if } i = 1, \\ \max\{|\tau_{i-1}|, |\tau_i|\}h_i \leq \max\left\{1, \frac{h_i}{h_{i-1}}\right\} \cdot \omega(f, h) & \text{if } i \in \{2, \dots, n\}, \end{cases}$$

$$|m_i|h_i \leq \begin{cases} \max\{|\tau_i|, |\tau_{i+1}|\}h_i \leq \max\left\{1, \frac{h_i}{h_{i+1}}\right\} \cdot \omega(f, h) & \text{if } i \in \{1, \dots, n-1\}, \\ \max\left\{|\tau_n|, \frac{|k\tau_n - (k - u_n + 1)\tau_{n-1}|}{u_n - 1}\right\}h_n \\ \leq \left(k + \frac{k - u_n + 1}{u_n - 1} \cdot \frac{h_n}{h_{n-1}}\right) \omega(f, h), & \text{if } i = n. \end{cases}$$

This leads to (6.7). Q.E.D.

In the case of monotone increasing and convex spline interpolation the dependence of C_0 on $\Omega(\pi)$ can be removed.

THEOREM 6.3. *Let $f \in C[a, b]$ be given such that for the corresponding data set a monotone increasing and convex interpolation spline of the form (2.4), (2.5) can be found. Then the error between f and such a spline s is bounded by*

$$\|f - s\| \leq C_1 \cdot \omega(f, h)$$

with $C_1 = \max\{7/2, 1 + 2(k - 1)/\tilde{q}\}$.

Proof. Starting from the representation

$$s(x) = f_{i-1} + m_{i-1}h_it + a_{k,u_i} \cdot \int_0^t \int_0^\eta \xi^{k-u_i-1}(1-\xi)^{u_i-2}(\lambda_i\xi + \rho_i) d\xi d\eta$$

for $x \in [x_{i-1}, x_i]$, with λ_i, ρ_i from (6.2), (6.3), and using the identity

$$\int_0^1 \int_0^\eta \xi^\mu (1-\xi)^\nu d\xi d\eta = \frac{\mu + 1}{\mu + \nu + 2} \int_0^1 \xi^\nu (1-\xi)^\mu d\xi$$

for arbitrary integers μ, ν (see [15]), we obtain after straightforward calculation

$$|s(x) - f(x)| \leq |f_{i-1} - f(x)| + m_{i-1}h_i + |\lambda_i|h_i + \frac{k}{k - u_i} \cdot \rho_i h_i.$$

Finally, (6.4), (6.5) and $m_{i-1} \geq 0$ yield

$$|s(x) - f(x)| \leq \omega(f, h) + |\lambda_i|h_i + \frac{k}{u_i} \cdot \omega(f, h)$$

$$\leq \left[1 + \frac{k}{u_i} + \max\left\{\frac{k - u_i}{u_i}, 1\right\}\right] \cdot \omega(f, h) \leq C_1 \cdot \omega(f, h). \quad \text{Q.E.D.}$$

Remark. With Theorem 6.1 we have obtained a better error estimate than that given by Neuman in [12], [13] for special cases.
