# CLASSIFICATION OF TERNARY EXTREMAL SELF-DUAL CODES OF LENGTH 28

MASAAKI HARADA, AKIHIRO MUNEMASA, AND BORIS VENKOV

ABSTRACT. All 28-dimensional unimodular lattices with minimum norm 3 are known. Using this classification, we give a classification of ternary extremal self-dual codes of length 28. Up to equivalence, there are 6,931 such codes.

#### 1. Introduction

As described in [21], self-dual codes are an important class of linear codes for both theoretical and practical reasons. It is a fundamental problem to classify self-dual codes of modest length and determine the largest minimum weight among self-dual codes of that length. By the Gleason–Pierce theorem, there are nontrivial divisible self-dual codes over  $\mathbb{F}_q$  for q=2,3 and 4 only, where  $\mathbb{F}_q$  denotes the finite field of order q; this is one of the reasons why much work has been done concerning self-dual codes over these fields.

A ternary self-dual code C of length n is a code over  $\mathbb{F}_3$  satisfying  $C = C^{\perp}$  where the dual code  $C^{\perp}$  of C is defined as  $C^{\perp} = \{x \in \mathbb{F}_3^n | x \cdot y = 0 \text{ for all } y \in C\}$  under the standard inner product  $x \cdot y$ . A ternary self-dual code of length n exists if and only if  $n \equiv 0 \pmod{4}$ . It was shown in [18] that the minimum weight d of a self-dual code of length n is bounded by  $d \leq 3[n/12] + 3$ . If d = 3[n/12] + 3, then the code is called extremal.

All ternary self-dual codes of length  $\leq 20$  have been classified [5, 17, 20]. At length 24, the complete classification has not yet been done, but by showing that every ternary extremal self-dual code is generated by the rows of some Hadamard matrix of order 24, it is shown that there are exactly two inequivalent extremal self-dual codes [16] (see [14] for known results on the classification).

The aim of this paper is to establish the following classification.

**Theorem 1.** There are exactly 6,931 inequivalent ternary extremal self-dual codes of length 28.

Generator matrices of all codes can be obtained electronically from [11]. All computer calculations in this paper were done using Magma [4].

Received by the editor January 29, 2008 and, in revised form, June 9, 2008.

<sup>2000</sup> Mathematics Subject Classification. Primary 94B05; Secondary 11H71.

Key words and phrases. Extremal self-dual code, unimodular lattice, frame.

#### 2. Self-dual codes and unimodular lattices

Let  $\mathbb{Z}_k$  be the ring of integers modulo k, where k is a positive integer. Although we shall exclusively deal with the special case k=3 (and hence  $\mathbb{Z}_k=\mathbb{F}_3$ ) in later sections, we discuss the general case here since the presentation remains the same for all k. A code C of length n over  $\mathbb{Z}_k$  (or a  $\mathbb{Z}_k$ -code of length n) is a  $\mathbb{Z}_k$ -submodule of  $\mathbb{Z}_k^n$ . A code C is self-dual if  $C=C^\perp$  where the dual code  $C^\perp$  of C is defined as  $C^\perp=\{x\in\mathbb{Z}_k^n\mid x\cdot y=0 \text{ for all }y\in C\}$  under the standard inner product  $x\cdot y$ . Two  $\mathbb{Z}_k$ -codes C and C' are equivalent if there exists a monomial  $(\pm 1,0)$ -matrix P with  $C'=C\cdot P=\{xP\mid x\in C\}$ . The automorphism group  $\mathrm{Aut}(C)$  of C is the group of all monomial  $(\pm 1,0)$ -matrices P with  $C=C\cdot P$ .

A (Euclidean) lattice L in dimension n is integral if  $L \subseteq L^*$ , where the dual lattice  $L^*$  is defined as  $L^* = \{x \in \mathbb{R}^n | (x,y) \in \mathbb{Z} \text{ for all } y \in L\}$  under the standard inner product (x,y). An integral lattice with  $L = L^*$  is called unimodular. The norm of a vector x is (x,x). The minimum norm of L is the smallest norm among all nonzero vectors of L. The theta series  $\theta_L(q)$  of L is the formal power series  $\theta_L(q) = \sum_{x \in L} q^{(x,x)} = \sum_{m=0}^{\infty} N_m q^m$ , where  $N_m$  is the number of vectors of norm m. The kissing number is the second nonzero coefficient of the theta series, that is, the number of vectors of L with minimum norm. Two lattices L and L' are isomorphic, denoted  $L \cong L'$ , if there exists an orthogonal matrix A with  $L' = L \cdot A$ . The automorphism group Aut(L) of L is the group of all orthogonal matrices A with  $L = L \cdot A$ .

For a  $\mathbb{Z}_k$ -code C of length n,

$$A_k(C) = \frac{1}{\sqrt{k}} \{ (x_1, \dots, x_n) \in \mathbb{Z}^n \mid (x_1 \bmod k, \dots, x_n \bmod k) \in C \}$$

is a lattice, and  $A_k(C)^* = A_k(C^{\perp})$  holds (see e.g., [3, Lemma 3.1]). In particular, C is self-dual if and only if  $A_k(C)$  is unimodular. This construction of lattices from codes is called Construction A. Clearly, if  $\mathbb{Z}_k$ -codes C and C' are equivalent, then the lattices  $A_k(C)$  and  $A_k(C')$  are isomorphic. Indeed, if P is a monomial  $(\pm 1, 0)$ -matrix and  $C' = C \cdot P$ , then  $A_k(C) \cdot P = A_k(C')$ .

A set  $\{f_1, \ldots, f_n\}$  of n vectors  $f_1, \ldots, f_n$  in an n-dimensional lattice L with  $(f_i, f_j) = k\delta_{ij}$  is called a k-frame of L, where  $\delta_{ij}$  is the Kronecker delta. Clearly,  $A_k(C)$  has a k-frame. Conversely, self-dual codes over  $\mathbb{Z}_k$  correspond to k-frames in unimodular lattices. To state this precisely and more generally, we consider an arbitrary integral lattice L in dimension n, and let  $\mathcal{F} = \{f_1, \ldots, f_n\}$  be a k-frame of L. Consider the mapping

$$\pi_{\mathcal{F}} : \frac{1}{k} \bigoplus_{i=1}^{n} \mathbb{Z} f_{i} \to \mathbb{Z}_{k}^{n},$$
  
$$\pi_{\mathcal{F}}(x) = ((x, f_{i}) \bmod k)_{1 \le i \le n}.$$

Then  $\operatorname{Ker} \pi_{\mathcal{F}} = \bigoplus_{i=1}^n \mathbb{Z} f_i \subset L$ , so the code  $C = \pi_{\mathcal{F}}(L)$  satisfies  $\pi_{\mathcal{F}}^{-1}(C) = L$ . This implies  $A_k(C) \cong L$  and every code C with  $A_k(C) \cong L$  is obtained as  $\pi_{\mathcal{F}}(L)$  for some k-frame  $\mathcal{F}$  of L. In particular, if L is unimodular, then  $\pi_{\mathcal{F}}(L)$  is self-dual and every self-dual code C with  $A_k(C) \cong L$  is obtained in this way.

**Lemma 2.** Let L be an integral lattice in dimension n, and let  $\mathcal{F} = \{f_1, \ldots, f_n\}$ ,  $\mathcal{F}' = \{f'_1, \ldots, f'_n\}$  be k-frames of L. Then the codes  $\pi_{\mathcal{F}}(L)$  and  $\pi_{\mathcal{F}'}(L)$  are equivalent if and only if there exists an orthogonal matrix  $P \in \operatorname{Aut}(L)$  such that

$$\{\pm f_1, \dots, \pm f_n\} \cdot P = \{\pm f'_1, \dots, \pm f'_n\}.$$

Proof. Let  $C = \pi_{\mathcal{F}}(L)$ ,  $C' = \pi_{\mathcal{F}'}(L)$ . Since  $A_k(C \cdot Q) = A_k(C) \cdot Q$  for a monomial  $(\pm 1, 0)$ -matrix Q, the codes C and C' are equivalent if and only if  $A_k(C) \cdot Q = A_k(C')$  for some monomial  $(\pm 1, 0)$ -matrix Q. Let F and F' denote the  $n \times n$  matrices whose row vectors consist of the elements of  $\mathcal{F}$  and  $\mathcal{F}'$ , respectively. Then

$$A_k(C) \cdot \frac{1}{\sqrt{k}} F = A_k(C') \cdot \frac{1}{\sqrt{k}} F' = L.$$

This implies that the codes C and C' are equivalent if and only if  $\frac{1}{k}F^TQF' \in \operatorname{Aut}(L)$  for some monomial  $(\pm 1, 0)$ -matrix Q. This occurs precisely when FP = QF' for some  $P \in \operatorname{Aut}(L)$ .

#### 3. Methods of classification

In this section, we describe our approach for classifying ternary extremal self-dual codes of length 28.

The minimum norm of a unimodular lattice in dimension 28 is at most 3 (see [6, Chapter 19]). We say that such a unimodular lattice with minimum norm 3 is optimal. There are 38 non-isomorphic optimal unimodular lattices in dimension 28 [2]. In [2], the 38 optimal unimodular lattices are denoted by  $\mathbf{R}_{28,1}(\emptyset)$ ,  $\mathbf{R}_{28,2}(\emptyset)$ , ...,  $\mathbf{R}_{28,36}(\emptyset)$ ,  $\mathbf{R}_{28,37e}(\emptyset)$ ,  $\mathbf{R}_{28,38e}(\emptyset)$ . These lattices have the following theta series:

(1) 
$$\theta_{\mathbf{R}_{28,i}(\emptyset)}(q) = 1 + 2240q^3 + 98280q^4 + \cdots \quad (i = 1, 2, \dots, 36),$$

(2) 
$$\theta_{\mathbf{R}_{28,i}(\emptyset)}(q) = 1 + 1728q^3 + 106472q^4 + \cdots \ (i = 37e, 38e).$$

In order to distinguish lattices, some polynomial  $m_v(x)$  is defined in [2, p. 239]. We remark that the polynomial  $m_v(x)$  has a misprint, namely, " $\langle v, \alpha \rangle = 1$ " should be " $\langle v, \alpha \rangle = -1$ ".

If C is a self-dual code with minimum weight d, then  $A_3(C)$  is a unimodular lattice with minimum norm min $\{3, d/3\}$ . Thus, if C is an extremal self-dual code of length 28, then  $A_3(C)$  is an optimal unimodular lattice. An extremal self-dual code C of length 28 has the following weight enumerator:

$$1 + 2184y^9 + 78624y^{12} + 768096y^{15} + 2159976y^{18} + \cdots$$

Since a codeword of weight 9 gives a vector of norm 3 in the lattice  $A_3(C)$ ,  $A_3(C)$  has exactly  $2184 + 2 \cdot 28$  vectors of norm 3. Hence we have the following:

**Lemma 3.** Let C be a ternary extremal self-dual code of length 28. Then the lattice  $A_3(C)$  has theta series (1).

**Lemma 4.** Let L be an optimal unimodular lattice in dimension 28 having a 3-frame  $\{u_1, \ldots, u_{28}\}$ . Let  $L_0$  be the even sublattice of the lattice L. If  $u \in L_0^* \setminus L$ , then

(3) 
$$u = \frac{1}{6} \sum_{i=1}^{28} \lambda_i u_i$$

for some odd integers  $\lambda_1, \ldots, \lambda_{28}$ .

*Proof.* Follows from [10, Lemma 2].

**Lemma 5.** Let C be a ternary extremal self-dual code of length 28. Let  $\{u_1, \ldots, u_{28}\}$  be a 3-frame of  $L = A_3(C)$  coming from C. Let  $L_0$  be the even sublattice of the lattice L. Then  $L_0^*$  has minimum norm 3. Moreover, for any vector  $u \in L_0^* \setminus L$  of norm 3, there exists a unique  $i_0 \in \{1, \ldots, 28\}$  such that

$$|(u, u_i)| = \begin{cases} \frac{3}{2} & \text{if } i = i_0, \\ \frac{1}{2} & \text{otherwise.} \end{cases}$$

*Proof.* Since C has minimum weight 9, L has minimum norm 3. Hence  $L_0$  has minimum norm 4 (see also [10, Lemma 1]). Let  $u \in L_0^* \setminus L$  and write u as in (3). Then by Lemma 4, we have

$$28 \le \sum_{i=1}^{28} \lambda_i^2$$

$$= \frac{1}{3} \sum_{i=1}^{28} (\lambda_i u_i, \lambda_i u_i)$$

$$= \frac{1}{3} (6u, 6u)$$

$$= 12(u, u).$$

Since  $(u, u) \in \mathbb{Z}$  we have  $(u, u) \geq 3$ , and equality holds if and only if there exists a unique  $i_0 \in \{1, \ldots, 28\}$  such that

$$|\lambda_i| = \begin{cases} 3 & \text{if } i = i_0, \\ 1 & \text{otherwise,} \end{cases}$$

and the assertion follows.

Remark 6. By Lemma 3, L has theta series (1). From [6, p. xlv], the shadow  $L_0^* \setminus L$  has minimum norm 3. This gives an alternative proof of the assertion that  $L_0^*$  has minimum norm 3.

For a lattice L, a vector u not necessarily in L, an integer m and a real number c, set

(4) 
$$L_{m,c}(u) = \{ v \mid v \in L, \ (v,v) = m, \ (u,v) = \pm c \}.$$

**Lemma 7.** Let L be an optimal unimodular lattice in dimension 28. Let  $S_3$  be the set of vectors of norm 3 in  $L_0^* \setminus L$ . Let  $u_1, u_2$  be orthogonal vectors of norm 3 in L. If there exists a 3-frame containing  $u_1$  and  $u_2$ , then

(5) 
$$\{u_1, u_2\} \not\subset L_{3,3/2}(u) \text{ for all } u \in S_3.$$

 ${\it Proof.}$  Immediate from Lemma 5.

Let L be a 28-dimensional optimal unimodular lattice with kissing number 2240. Let  $L_3$  be the set  $\{\{x, -x\} | (x, x) = 3, x \in L\}$  and let  $S_3$  be the set  $\{x | (x, x) = 3, x \in L^* \setminus L\}$ . We define the simple undirected graph  $\Gamma$ , whose set of vertices is the set of 1120 pairs in  $L_3$  and two vertices  $\{x, -x\}, \{y, -y\} \in L_3$  are adjacent if (x, y) = 0 and  $\{x, y\} \not\subset L_{3,3/2}(u)$  for any  $u \in S_3$ . It follows that the 3-frames are precisely the 28-cliques in the graph  $\Gamma$ . We could have defined  $\Gamma$  as the "orthogonality graph," by simply joining two vertices  $\{x, -x\}, \{y, -y\} \in L_3$  whenever (x, y) = 0. The effect

of Lemma 7 is to remove those edges from the "orthogonality graph" which cannot be contained in 3-frames. This speeds up the computations considerably. It is clear that  $\operatorname{Aut}(L)$  acts on the graph  $\Gamma$  as automorphisms, and Lemma 2 implies that the  $\operatorname{Aut}(L)$ -orbits on the set of 28-cliques in  $\Gamma$  are in one-to-one correspondence with the equivalence classes of codes C satisfying  $A_3(C) \cong L$ . Therefore, the classification of such codes reduces to finding a set of representatives of 28-cliques in  $\Gamma$  up to the action of  $\operatorname{Aut}(L)$ . This computation was performed using Magma, the results were then converted to 3-frames, and then to ternary extremal self-dual codes of length 28. In this way, by considering all 28-dimensional optimal unimodular lattices with kissing number 2240, we have all inequivalent extremal self-dual codes of length 28 by Lemma 3.

Remark 8. From the odd Leech lattice which is the unique odd unimodular lattice with minimum norm 3 in dimension 24, we can define the "orthogonality graph" as above. Classifying 24-cliques up to the automorphism group of the odd Leech lattice, we have verified that there are exactly two 3-frames in the odd Leech lattice up to conjugacy under the automorphism group. This confirms the known classification (see [16]) of ternary extremal self-dual codes of length 24.

### 4. Results of Classification

By the approach described in Section 3, we completed the classification of ternary extremal self-dual codes of length 28. The number  $F_i$   $(i=1,2,\ldots,36)$  of 3-frames in  $\mathbf{R}_{28,i}(\emptyset)$  is listed in Table 1. The number  $N_i$   $(i=1,2,\ldots,36)$  of inequivalent extremal self-dual codes C with  $A_3(C) \cong \mathbf{R}_{28,i}(\emptyset)$  is also listed in Table 1. The last column  $(\# \operatorname{Aut}, N_i(\# \operatorname{Aut}))$  in Table 1 lists the number  $N_i(\# \operatorname{Aut})$  of the codes whose automorphism groups have order  $\# \operatorname{Aut}$ . Therefore, we have Theorem 1. As a corollary, we have the following:

**Corollary 9.** A 28-dimensional optimal unimodular lattice L can be constructed from some ternary extremal self-dual code of length 28 by Construction A if and only if L is isomorphic to  $\mathbf{R}_{28,i}(\emptyset)$  for some  $i=1,2,\ldots,27,29,\ldots,33,35,36$ .

We investigate the previously known extremal self-dual codes of length 28. Huffman [13] showed that there are 14 and 5 inequivalent extremal self-dual [28, 14, 9] codes with automorphisms of orders 7 and 13, respectively. Denote the 14 codes with automorphisms of order 7 by  $H_{7,1}, \ldots, H_{7,14}$ , and the 5 codes with automorphisms of order 13 by  $H_{13,1}, \ldots, H_{13,5}$ , according to the order in [13, Theorem 4]. However, he did not check if there is a pair of equivalent codes  $H_{7,i}$  and  $H_{13,j}$  among these codes. We have verified that the codes  $H_{7,2}$  and  $H_{13,2}$  are equivalent and the codes  $H_{7,14}$  and  $H_{13,3}$  are equivalent.

In [8], 16 inequivalent extremal self-dual codes which are inequivalent to any of the codes in [13] are constructed and these codes are denoted by  $C_{28,1}, \ldots, C_{28,16}$  in [8]. We remark that the existence of some extremal ternary self-dual code of length 28 with trivial automorphism group is announced in [9] and one example of such a code is given. However, we have verified that the code with generator matrix  $G_{28}$  given in [9] is equivalent to  $C_{28,1}$ . Hence 33 inequivalent extremal self-dual codes are previously known explicitly. We have verified that all of these 33 codes appear in the present classification, and we list the order  $\# \operatorname{Aut}(C)$  of the automorphism group and the lattice  $\mathbf{R}_{28,i}(\emptyset)$  with  $A_3(C) \cong \mathbf{R}_{28,i}(\emptyset)$  in Table 2.

Table 1. Ternary extremal self-dual codes of length 28

For those lattices  $\mathbf{R}_{28,i}(\emptyset)$  which are not listed in Table 2, we list a code  $C_i$  with  $\mathbf{R}_{28,i}(\emptyset) \cong A_3(C_i)$  where the rows of the matrix  $M_i$  in a generator matrix  $(I, M_i)$  of  $C_i$  are given in Table 3. The order  $\# \operatorname{Aut}(C_i)$  of the automorphism group of  $C_i$  is also listed.

The lattice  $\mathbf{R}_{28,35}(\emptyset)$  was constructed by Nebe [19], and it can be given simply as

$$\Lambda = E_8 \wedge E_8,$$

where  $E_8$  denotes the root lattice of type  $E_8$ . The unique code C with  $A_3(C) \cong \Lambda$  can be constructed from a 3-frame of the lattice  $\Lambda$ , which we shall now describe.

Let  $e_1, \ldots, e_9$  denote an orthonormal basis of the vector space  $\mathbb{R}^9$ . The  $\mathbb{Z}$ -linear span of  $\{e_i - e_j \mid 1 \leq i < j \leq 9\}$  is known as the  $A_8$ -lattice. For a subset T of  $\{1, \ldots, 9\}$ , we denote by  $e_T$  the vector  $\sum_{i \in T} e_i$ , and by  $\bar{T}$  the complementary set of T in  $\{1, \ldots, 9\}$ . Let T denote the set of all 3-subsets of the set  $\{1, \ldots, 9\}$ . Then, together with the 72 roots of  $A_8$ , the  $2\binom{9}{3} = 168$  roots  $\{\pm \frac{1}{3}(2e_T - e_{\bar{T}}) \mid T \in T\}$  form the root system  $E_8$ . The group PSL(2, 8) acts triply transitively on the

Table 2. The automorphism groups and lattices of known codes

projective line  $\mathbb{F}_8 \cup \{\infty\}$ . Identifying  $\mathbb{F}_8 \cup \{\infty\}$  with  $\{1, \dots, 9\}$ , we regard PSL(2, 8) as a permutation group on the set  $\{1, \dots, 9\}$ . The group PSL(2, 8) has a unique conjugacy class  $\mathcal{C}$  of fixed-point-free elements of order 3. This conjugacy class  $\mathcal{C}$  contains 28 pairs of elements and their inverses. Let  $x \in \mathcal{C}$ , and let  $T_1, T_2, T_3$  be the  $\langle x \rangle$ -orbits on  $\{1, \dots, 9\}$ . Define  $f_x \in \Lambda$  by

$$f_x = \frac{1}{3}(e_{T_1} \wedge e_{T_2} + e_{T_2} \wedge e_{T_3} + e_{T_3} \wedge e_{T_1}).$$

Note that  $f_x$  is not uniquely determined by x, but determined up to sign. The set  $\{\pm f_x \mid x \in \mathcal{C}\}$  forms a 3-frame in the lattice  $\Lambda$ . One obtains an extremal ternary self-dual code of length 28 from this 3-frame of  $\Lambda$ .

Finally, we remark that the lattice  $\mathbf{R}_{28,36}(\emptyset)$  was first constructed in [1], and 3-frames of the lattice  $\mathbf{R}_{28,36}(\emptyset)$  correspond to symplectic spreads in  $\mathbb{F}_3^6$ , as pointed out in [2, Remark 2.1]. Consequently, our classification gives an alternative proof of the classification of symplectic spreads in  $\mathbb{F}_3^6$ , given in [7].

### 5. Covering radii and 3-designs

The covering radius R(C) of a code C of length n is the smallest integer R such that spheres of radius R around codewords of C cover the space  $\mathbb{F}_3^n$ . For linear codes, the covering radius is the largest weight of all coset leaders of the code. The covering radius is a basic and important geometric parameter of a code. Let C be an extremal self-dual code of length 28. Then, by the sphere-covering bound and the Delsarte bound, it is known that R(C) = 6 or 7 (see [12, Table 1]). Using our classification, explicit calculations show the following:

Proposition 10. Every extremal self-dual code of length 28 has covering radius 7.

A t- $(v, k, \lambda)$  design is a set X of v points together with a collection  $\mathcal{B}$  of k-subsets of X called blocks such that every t-subset of X is contained in exactly  $\lambda$  blocks. Two designs with the same parameters are isomorphic if there is a bijection between their point sets that maps the blocks of the first design into blocks of the second design. The automorphism group  $\operatorname{Aut}(D)$  of a t-design D is the group of all isomorphisms of D with itself. If a 3- $(28, 9, \lambda)$  design exists, then  $\lambda$  must be divisible by 28 (see [15, p. 57]). Hence 3-(28, 9, 28) designs have the smallest  $\lambda$  among 3- $(28, 9, \lambda)$  designs.

By the Assmus–Mattson theorem, the supports of the codewords of minimum weight in an extremal self-dual code of length 28 form a 3-(28, 9, 28) design. We have verified that the 6,931 3-(28, 9, 28) designs obtained from the extremal self-dual codes are non-isomorphic. Thus we have the following:

**Proposition 11.** There are at least 6,931 non-isomorphic 3-(28, 9, 28) designs.

Remark 12. We have verified that every extremal self-dual code of length 28 is generated by the codewords of minimum weight.

For every extremal self-dual code C of length 28, we have verified that the order of the automorphism group of the 3-(28, 9, 28) design obtained from C is half of the order of the automorphism group of C.

## ACKNOWLEDGMENT

The authors would like to thank Gabriele Nebe for helpful discussions.
