FUNCTIONS WITH PRESCRIBED LIPSCHITZ CONDITION

W. S. LOUD

1. Introduction. In this note we construct a class of functions each of which satisfies at every point a Lipschitz condition of prescribed order α ($0 < \alpha < 1$). The construction is based on a method given by Knopp [1]¹ for construction of continuous nondifferentiable functions, and follows more particularly a construction of van der Waerden [2].

2. The construction. We first define a fundamental periodic function $g(t, h)$. The function $g(t, h)$ has period $2h$ in t , equals zero for even multiples of h , equals one for odd multiples of h , and is linear between successive multiples of h . It is thus a saw-tooth function of t .

Now let a number α be given, where $0 < \alpha < 1$. Let A be an integer for which

$$2^{2A(1-\alpha)} > 2.$$

The function we are constructing is

$$g(t) = \sum_{n=1}^{\infty} 2^{-2A\alpha n} g(t, 2^{-2A n}).$$

It will be shown that $g(t)$ satisfies for each value of t a Lipschitz condition of order precisely α .

3. Proof of Lipschitz condition.

THEOREM. *The function $g(t)$ defined above satisfies for each value of t a Lipschitz condition of order precisely α . That is, there exist two positive constants K_1 and K_2 such that*

(a) *for any t and any Δt ,*

$$|\Delta g| < K_1 |\Delta t|^\alpha$$

where $\Delta g = g(t + \Delta t) - g(t)$, and

(b) *for any t and for infinitely many, arbitrarily small Δt ,*

$$|\Delta g| > K_2 |\Delta t|^\alpha.$$

PROOF. We shall denote the k th summand of the series for $g(t)$ by g_k . To prove assertion (a) we let m be the integer such that

$$2^{-2A(m+1)} < \Delta t \leq 2^{-2A m}.$$

Received by the editors May 6, 1950.

¹ Numbers in brackets refer to the bibliography at the end of the paper.

Since the slope of the linear portions of $g_k(t)$ is $\pm 2^{2Ak(1-\alpha)}$,

$$|\Delta g_k| \leq 2^{2Ak(1-\alpha)} |\Delta t| \leq 2^{2Ak(1-\alpha)-2Am} \quad (k \leq m).$$

Since the maximum oscillation of $g_k(t)$ is $2^{-2A\alpha k}$,

$$|\Delta g_k| \leq 2^{-2A\alpha k} \quad (k > m).$$

Combining the above,

$$\begin{aligned} |\Delta g| &\leq \sum_{k=1}^m 2^{-2Am} 2^{2A(1-\alpha)k} + \sum_{k=m+1}^{\infty} 2^{-2A\alpha k} \\ &\leq \frac{2^{2A(1-\alpha)-2A\alpha m}}{2^{2A(1-\alpha)} - 1} + \frac{2^{-2A\alpha(m+1)}}{1 - 2^{-2A\alpha}}. \end{aligned}$$

Now $|\Delta t|^\alpha > 2^{-2A\alpha(m+1)}$. Therefore

$$\frac{|\Delta g|}{|\Delta t|^\alpha} < \frac{2^{2A}}{2^{2A(1-\alpha)} - 1} + \frac{1}{1 - 2^{-2A\alpha}},$$

which proves assertion (a).

To prove assertion (b) we use a lemma on geometrical progressions.

LEMMA. *If the ratio in a geometric progression is positive and less than 1/2, and the first term is 1, then the first term exceeds the sum of the remaining terms by at least*

$$\frac{1 - 2r}{1 - r}.$$

PROOF OF LEMMA. If the progression is infinite, the sum of the terms following the first is $r/(1-r)$, and if the progression is finite the sum of the terms following the first is less than this. If $r < 1/2$, $r/(1-r) < 1$, so that the first term, 1, exceeds the sum of the remaining terms by at least

$$1 - r/(1-r) = (1-2r)/(1-r).$$

Turning now to the proof of (b), for a given t let Δt be equal numerically to

$$2^{-2A(m+1)}$$

and in a direction so as not to include a multiple of 2^{-2Am} , where m is any positive integer. For this Δt ,

$$\Delta g_k = 0 \quad (k > m)$$

while

$$\Delta g_k = \pm 2^{2A k(1-\alpha)} 2^{-2A(m+1)} \quad \text{if } k \leq m.$$

Thus

$$\begin{aligned} \Delta g &= 2^{-2A(m+1)} [\pm 2^{2A m(\alpha-1)} \pm 2^{2A(m-1)(1-\alpha)} \pm \dots \pm 2^{2A(1-\alpha)}] \\ &= 2^{-2A-2A m\alpha} [\pm 1 \pm 2^{-2A(1-\alpha)} \pm 2^{-4A(1-\alpha)} \pm \dots]. \end{aligned}$$

Now since A was chosen so that $2^{-2A(1-\alpha)} < 1/2$, we may apply the lemma and conclude that

$$|\Delta g| > 2^{-2A-2A m\alpha} \frac{1 - 2^{-2A(1-\alpha)} \cdot 2}{1 - 2^{-2A(1-\alpha)}}.$$

Now $|\Delta t|^\alpha = 2^{-2A m\alpha - 2A\alpha}$. Therefore

$$\frac{|\Delta g|}{|\Delta t|^\alpha} > 2^{-2A(1-\alpha)} \frac{1 - 2 \cdot 2^{-2A(1-\alpha)}}{1 - 2^{-2A(1-\alpha)}},$$

and since this is true for any m , assertion (b) is proved.

It should be remarked that for any α in the range $0 < \alpha < 1$ the function $g(t)$ is continuous and nondifferentiable.
