A FIXED POINT THEOREM

B. O'NEILL AND E. G. STRAUS¹

1. The fixed point theorem. Let $T: X \rightarrow Y$ be a point-to-set function and let $T^{-1}: Y \rightarrow X$ be the point-to-set function such that $x \in T^{-1}(y)$ if and only if $y \in T(x)$. If X and Y are topological spaces, T is *continuous* provided the function T^{-1} is both open and closed, and each set $T(x)$ is closed.

Let H be Čech homology theory with coefficients in a field, and let E_n be Euclidean n -space. A mapping $f: B \rightarrow E_n$ will be said to *link* a point of E_n provided that $x \notin f(B)$ and the induced homomorphism $f_*: H_{n-1}(B) \rightarrow H_{n-1}(E_n - x)$ is not zero.

THEOREM. *Let C be a compact connected subspace of E_n and let $T: C \rightarrow C$ be a continuous point-to-set function. Let B be a compact space, I the unit interval, with $h: B \times I \rightarrow E_n$ a homotopy such that h_0 links every point of C and h_1 links no point of C . Then there exists a number t with $0 < t \leq 1$ and a point $y \in C$ such that $y \in h_t(B)$ and $h_t(B)$ meets $T(y)$.*

(Here, as usual, h_t denotes the map of B into E_n such that $h_t(b) = h(b, t)$). We note that the hypothesis on h is fulfilled in case B is the boundary of a bounded open set containing C and h is a deformation of B such that $E_n - h_1(B)$ is connected.

To prove the theorem we need the following lemmas.

LEMMA 1 (Notation as in Theorem). *In the space $C \times E_1$, let $U = \{(x, t) \mid t < 0\}$, $V = \{(x, t) \mid t > 1\}$, $B^* = \{(x, t) \mid x = h(b, t) \text{ for some } b \in B\}$. Then U and V are contained in different components of $C \times E_1 - B^*$.*

PROOF. Let L be the set of points (x, t) of $C \times I$ such that h_t links x . In view of the hypotheses on h_0 and h_1 , it suffices to prove that L and $C \times I - (B^* \cup L)$ are open in $C \times I$. If $(x, t) \in C \times I - B^*$, there is an ϵ -neighborhood N of x in E_n and a neighborhood P of t in I such that if $u \in P$ then $h_u(B) \cap N = \emptyset$. Consider the neighborhood $(N \cap C) \times P$ of (x, t) in $C \times I$. If (y, u) is in this neighborhood, then h_t and h_u are homotopic, considered as maps into $E_n - N$. But the inclusion maps of $E_n - N$ into $E_n - x$ and $E_n - y$ induce homology isomorphisms. Thus h_t links x if and only if h_u links y , and the proof is complete.

A subset A of a space X will be said to *separate* two points a and b of X provided every compact connected subset F of X containing a and b meets A .

LEMMA 2. *Let the points a and b of a compact space X be separated by a closed subset A of X . If the homology group $H_1(X)$ is zero, then there is a compact connected subset K of A which separates a and b .*

PROOF. An application of Zorn's lemma shows that there is a minimal compact subset K of A which separates a and b . But K is connected, for if not K can be expressed as the union of two disjoint nonempty closed subsets of X neither of which separates a and b . However this would contradict Theorem VII 9.2 of [1].

LEMMA 3. *If $T: X \rightarrow Y$ is a continuous point-to-set function from a compact connected space X onto a compact space Y and if L is a component of Y , then $T^{-1}(L) = X$.*

PROOF. The set L is the intersection of its open-and-closed neighborhoods N_α , and since T is continuous and X connected, $T^{-1}(N_\alpha) = X$ for each α . Thus the closed sets $T(x) \cap N_\alpha$ are all nonempty, and for a particular $x \in X$ the collection $\{T(x) \cap N_\alpha\}$ has the finite intersection property, so that $T(x)$ meets L .

PROOF OF THE THEOREM. Identify the points (x, t) of $C \times E_1$ for which $t \geq 2$ (call this point α) and the points for which $t \leq -1$ (call this point β). The resulting space $\tilde{C}$ is the two-point suspension of C . Using the Mayer-Vietoris sequence [2] one finds that since C is connected, $H_1(\tilde{C}) = 0$. By Lemma 1, B^* separates α and β in $\tilde{C}$, and thus, by Lemma 2, there is a compact connected subset K of B^* which also separates α and β . The function $T \times 1: C \times E_1 \rightarrow C \times E_1$ is continuous and determines in a natural way a continuous function $\tilde{T}: \tilde{C} \rightarrow \tilde{C}$. Let L be a component of the compact space $T(K)$. Suppose L and K are disjoint. By Lemma 3 $\tilde{T}^{-1}(L) = K$; hence in particular K and L have the same projections on E_1 . Thus there are arcs in $\tilde{C} - K$ from α and β to L . But this contradicts the fact that K separates α and β , hence L meets K . Thus there is a t , $0 < t \leq 1$, such that $T(h_t(B))$ meets $h_t(B)$.

Note that the theorem remains true if T is an upper semi-continuous function such that $T(x)$ is connected for each x , for then $\tilde{T}(K)$ is itself connected and can replace L in the preceding proof.

2. Applications. 1. Let B be an n -sphere in E_{n+1} and C a (concentric) n -sphere in the interior of B . Let $d \leq \text{diam } C$ and let h_t be as in the Theorem. Then some $B_t = h_t(B)$ will intersect C in points x, y with $d(x, y) = d$.

PROOF. Let C_x be the set of points on C whose distance from x is d . Then the mapping $T(x) = C_x$ is continuous.

REMARK. We can define the function $t(x)$ on C as the "time" t at which $x \in B_t$. This function is not necessarily single valued and therefore usually upper semi-continuous only but it is a function with connected graph. Thus the theorem of Kakutani-Yamabe-Yujobo [3] can be generalized for this function to yield that for some t the set $B_t \cap C$ contains the endpoints of $n+1$ mutually orthogonal radii of C .

2. W. Gustin has raised the following question. Given a convex surface C in E_3 what is the minimal length of a closed curve that can be "slipped over" C ? He remarked that the minimal perimeter of all orthogonal projections of C is obviously long enough to be slipped over C even without bending. I. Schoenberg has shown that this length is not minimal even for tetrahedra and conjectured that the minimal length is that of the minimal closed geodesic on C . There are good heuristic arguments in favor of this conjecture, but it has not been proved completely so far.²

With the help of our theorem we can obtain some information on the problem even without the assumption that C is convex.

The process of "slipping over" can be replaced by a varying simple closed curve K_t ($0 \leq t \leq 1$) on C whose closed interior expands from a point for K_0 to the whole of C for K_1 . This process can in turn be replaced by the shrinking of a surface B which contains C in its interior to a point in the interior of C , if we replace the interior of K_t on C by its image under a slight radial contraction towards a point P in the interior of C , and the exterior of K_t on C by its image under a slight radial dilation from P . We then connect the two pieces by the necessary part of the cone through K_t with vertex P .

Thus we can rephrase the problem. Let B be a closed surface containing the convex surface C . Let B be shrunk to a point so that $B_t \cap C$ is a rectifiable simple curve K_t , and let l be the maximum of the length of K_t . Then what is the minimum of l for all possible contractions B_t ?

From our theorem we know that for every continuous transformation T of C into itself, K_t will have to pass through a point x and intersect $T(x)$ for some t . Thus the mapping into diametrically opposite points proves Gustin's curves to be minimal for spheres and some other centrally symmetric surfaces (such as right circular cylinders and ellipsoids).

² Added in proof. Schoenberg's conjecture has been proved by H. Busemann and will appear in his book *Convex surfaces*, Interscience Publishers, New York.

We may obviously restrict our attention to arbitrarily smooth surfaces C . For such surfaces we can define the continuous mapping T which maps every point x into the set of points whose geodesic distance from x is no less than that of the nearest conjugate point of x . Thus we obtain that l is no less than twice the distance between the nearest conjugate points on C .

This investigation arose from a more special theorem of C. B. Tompkins. We wish to thank Arnold Shapiro for valuable suggestions.
