KNOPP'S CORE THEOREM AND SUBSEQUENCES OF A BOUNDED SEQUENCE

S. PARK AND G. LAUSH

Let s_n be a sequence in a p -dimensional Euclidean space E^p . Let $K_n = K(s_n, s_{n+1}, \dots)$ be the convex hull of $s_n, s_{n+1}, \dots$ and $\bar{K}_n$ its closure. The core of s_n is defined as $\bigcap_{n=1}^{\infty} \bar{K}_n$. Knopp's core theorem states that if $A = (a_{ij})$ is an infinite regular matrix with nonnegative elements, then the core of the A -transform of s_n is contained in the core of s_n . In particular if s_n is bounded, every A -limit of a subsequence of s_n is contained in the convex hull of limit points of s_n . With certain restrictions on A , the converse is also true; i.e., for any element ξ in the convex hull of limit points of s_n , there is a subsequence of s_n which is A -limitable to ξ . The main objective of this paper is to show that for any ξ in the convex hull of limit points of a bounded sequence s_n , there is a subsequence of s_n which is C_1 - and E_1 -limitable to ξ .

The following is Knopp's core theorem in E^p .

THEOREM 1. *Let s_n be a sequence in E^p and $A = (a_{ij})$ a regular matrix with $a_{ij} \geq 0$. Let K_n be the convex hull of $s_n, s_{n+1}, \dots$ and K'_n the convex hull of $s'_n, s'_{n+1}, \dots$, where $s'_n = \sum_{j=1}^{\infty} a_{nj}s_j$ is defined for each $n = 1, 2, \dots$. Then $\bigcap_{n=1}^{\infty} \bar{K}'_n \subset \bigcap_{n=1}^{\infty} \bar{K}_n$.*

PROOF. For each $\epsilon > 0$, define $K_{n\epsilon} = \{x \mid \inf_{y \in K_n} \|x - y\| \leq \epsilon\}$. For given m and $\epsilon > 0$, choose $\nu(m, \epsilon)$ so that

$$\left\| \sum_{j=1}^{m-1} a_{nj}s_j \right\| < \epsilon, \quad \left| \sum_{j=1}^{\infty} a_{nj} - 1 \right| < \epsilon, \quad \left| \sum_{j=1}^{m-1} a_{nj} \right| < \epsilon \quad \text{for } n \geq \nu.$$

Now choose an index $k(n)$ so that

$$\left\| \sum_{j=m+k+1}^{\infty} a_{nj}s_j \right\| < \epsilon, \quad \left| \sum_{j=m+k+1}^{\infty} a_{nj} \right| < \epsilon.$$

Then $\left| \sum_{j=m}^{m+k} a_{nj} - 1 \right| < 3\epsilon$. Assume $\epsilon < 1/3$ so that $\sum_{j=m}^{m+k} a_{nj} \neq 0$. Let $s'_n = \alpha_n + \beta_n + \gamma_n$ where

$$\alpha_n = \sum_{j=1}^{m-1} a_{nj}s_j, \quad \beta_n = \sum_{j=m+k+1}^{\infty} a_{nj}s_j, \quad \gamma_n = \sum_{j=m}^{m+k} a_{nj}$$

Received by the editors March 13, 1961 and, in revised form, November 28, 1961.

and

$$x_n = \frac{\sum_{j=m}^{m+k} a_{nj} s_j}{\sum_{j=m}^{m+k} a_{nj}}.$$

Since $x_n \in K_{m\epsilon}$ for every ϵ , $s'_n / \gamma_n \in K_{m\epsilon'}$ for $n \geq \nu$ where $\epsilon' = 2\epsilon / (1 - 3\epsilon)$, $|\gamma_n - 1| < 3\epsilon$.

Now let $\xi \in \bar{K}_n'$ for every n . Then $\xi \in K'_{n\delta}$ for every $\delta > 0$ and every n ; therefore $\xi = a_1 s'_{n_1} + \cdots + a_k s'_{n_k} + \eta$ where $\|\eta\| < \delta$, $n_i \geq \nu$ for each i , $a_i > 0$ and $\sum_{i=1}^k a_i = 1$. Since $s'_n / \gamma_n \in K_{m\epsilon'}$ for $n \geq \nu$, $\xi = \eta + \sum_{i=1}^k a_i x_{n_i} \gamma_{n_i}$ where $x_{n_i} \in K_{m\epsilon'}$ for $n_i \geq \nu$ and $|\gamma_{n_i} - 1| < 3\epsilon$. Let $\gamma = \sum_{i=1}^k a_i \gamma_{n_i}$, then $(1/\gamma)(\sum_{i=1}^k a_i \gamma_{n_i} x_{n_i}) \in K_{m\epsilon'}$; hence $\xi \in \bar{K}_m$ for every m .

It is clear that $\bigcap_{n=1}^{\infty} \bar{K}_n$ always contains limit points of s_n ; hence it contains the convex hull of limit points of s_n . Moreover if s_n is bounded $\bigcap_{n=1}^{\infty} \bar{K}_n$ is precisely the convex hull of limit points of s_n . To see this let Q be the set of limit points of s_n and $N_\epsilon(x)$ the ϵ -neighborhood of x . Then for each $\epsilon > 0$, $\bigcup_{x \in Q} N_\epsilon(x)$ contains all but a finite number of s_n . Now choose an index p so that $s_n \in \bigcup_{x \in Q} N_\epsilon(x)$ for $n \geq p$. Moreover since $\xi \in K_{m\delta}$ for every $\delta > 0$ and m , $\xi = \sum_{i=1}^k a_i s_{n_i} + \eta$ where $a_i \geq 0$, $\sum_{i=1}^k a_i = 1$, $n_i \geq p$ and $\|\eta\| < \delta$. Therefore there are $\xi_1, \xi_2, \dots, \xi_k$ in Q such that $\xi = \eta + \sum_{i=1}^k a_i \xi_i + \sum_{i=1}^k a_i \epsilon_i$ where $\|\epsilon_k\| \leq \epsilon$; therefore, $\xi \in K_{\epsilon+\delta}(Q)$. Hence $\xi \in \bar{K}(Q)$. The above remark and Knopp's core theorem give the following corollary.

COROLLARY 1. *If A is an infinite regular matrix with nonnegative elements, then every A -limit of a bounded sequence is in the convex hull of the limit points of the sequence.*

The following is a sufficient condition on a regular matrix so that the converse of Corollary 1 holds.

LEMMA 1. *Let A be a nonnegative regular matrix. Suppose there is a set of sequences $\mathbf{C}$ consisting of 0s and 1s with the following properties;*

(i) *For any $0 \leq \alpha \leq 1$, there is a sequence in $\mathbf{C}$ which is A -limitable to α .*

(ii) *If $\lim_{i \rightarrow \infty} \sum_{j=1}^{\infty} a_{ij} \epsilon_j = \lim_{i \rightarrow \infty} \sum_{k=1}^{\infty} a_{ik} = \alpha$ where $(\epsilon_i) \in \mathbf{C}$, then $\lim_{i \rightarrow \infty} \sum_{k=1}^{\infty} a_{ik} x_k = \alpha \beta$ if $(x_k) \in \mathbf{C}$ and is A -limitable to β .*

Then for any ξ in the convex hull of limit points of a bounded sequence s_n in E^p , there is a subsequence which is A -limitable to ξ .

PROOF. Let Q be the set of limit points of s_n , and let $\xi = \sum_{i=1}^m a_i \xi_i$ where $\xi_i \in Q$, $a_i > 0$, and $\sum_{i=1}^m a_i = 1$. Proceed by induction on m . If

$m=1$, then simply choose a subsequence of s_n which converges to ξ . Let $a = \sum_{i=1}^{k-1} a_i$, $b_i = a_i/a$, $\eta = \sum_{i=1}^{k-1} b_i \xi_i$ so that $\xi = \eta a + a_k \xi_k$. There is a subsequence s_{n_j} of s_n which is A -limitable to η . Also there is sequence ϵ_n in $\mathbf{C}$ so that

$$\lim_{t \rightarrow \infty} \sum_{j=1}^{\infty} a_{ij} \epsilon_j = \lim_{t \rightarrow \infty} \sum_{k=1}^{\infty} a_{ik} = a.$$

Let

$$y_m = \begin{cases} s_{n_j} & \text{if } m = j, \\ \xi_k & \text{otherwise.} \end{cases}$$

Now let y'_m be the sequence obtained from y_m replacing the terms which equal ξ_k by successive elements of s_n which converges to ξ_k so that y'_m is a subsequence of s_n . By induction it is easy to see that y'_m thus constructed is A -limitable to ξ .

The next problem is to find a set $\mathbf{C}$ of Lemma 1 for C_1 - and E_1 -processes.

LEMMA 2. *There is a set of sequences $\mathbf{C}$ of Lemma 1 for C_1 - and E_1 -processes.*

PROOF. Let $\alpha \in [0, 1]$ and $\alpha = 0 \cdot a_1 a_2 \cdots$ be a binary representation of α . For each positive integer $k \geq 2$ define a sequence s_n^k as follows,

$$s_{2n-1}^k = 0, \quad s_{2(2n-1)}^k = 0, \quad \cdots, \quad s_{2^{k-1}(2n-1)}^k = 1, \quad s_{2^k n}^k = 0$$

and for $k=1$, define $s_{2n-1}^1 = 1$, $s_{2n}^1 = 0$. Then s_n^k is C_1 -limitable to $1/2^k$ for each k , and $\sum_{k=1}^{\infty} s_n^k = 1$ for each n . Now the sequence defined by $s_n = \sum_{k=1}^{\infty} a_k s_n^k$ consists of the elements 0 and 1, and C_1 -limitable to α . The condition (ii) of Lemma 1 can easily be verified. Note that every sequence used in the proof satisfies the condition $(s_1 + \cdots + s_n)/n = \xi + o(1/\sqrt{n})$ where ξ is the C_1 -limit of s_n ; hence it is also E_1 -limitable to ξ . Lemma 1 and Lemma 2 give the following theorem.

THEOREM 2. *Let s_n be any bounded sequence in E^p . Let ξ be any element in the convex hull of limit points of s_n , then there is a subsequence of s_n which is C_1 - and E_1 -limitable (hence also Abel and Borel limitable) to ξ .*

In general it is not possible to extend the result to unbounded sequences. For example $0, 1, 0, 2, 0, 3, \cdots$ has no C_1 -limitable except the trivial ones. However, it can be shown that the sequence can be rearranged so that the resulting sequence is C_1 -limitable to

any pre-assigned nonnegative number. But the sequence $0, 1!, 0, 2!, 0, 3!, \dots$ does not even have this property. In general if s_n is a sequence having a limit point ξ and it has a subsequence $k_n \rightarrow \infty$ with $k_n/(k_1 + \dots + k_n) \rightarrow 0$, then for $\xi < \alpha < \infty$ it is possible to find a rearrangement of s_n whose C_1 -limit is α . Without loss of generality assume $\xi = 0$. Let $[(k_1 + \dots + k_n)/\alpha]$ be the greatest integer less than or equal to $(k_1 + \dots + k_n)/\alpha$. Construct a sequence y_n inserting 0s in $k_1, k_2, \dots$ so that the number of 0s preceding k_n is $[(k_1 + \dots + k_n)/\alpha]$. Then y_n is C_1 -limitable to α . Now there is a subsequence s_{n_k} of s_n which converges to 0. Replace each element in y_n which equals 0 by successive elements of s_{n_k} . Then the sequence y_n' thus constructed is C_1 -limitable to α . Now insert the rest of the elements of s_n in y_n' occasionally so that the resulting sequence has C_1 -limit α . This remark can be made also in E^p without much difficulty.
