A NOTE ON PERMUTATIONS IN AN ARBITRARY FIELD

L. CARLITZ¹

The writer [1] has proved that every permutation on the numbers of the finite field $GF(q)$ is generated by the special permutations

$$(1) \quad x^{q-2}, \quad \alpha x + \beta \quad (\alpha, \beta \in GF(q), \alpha \neq 0).$$

Let F denote an arbitrary field. Define the function

$$(2) \quad x^* = \begin{cases} x^{-1} & (x \in F, x \neq 0), \\ 0 & (x = 0). \end{cases}$$

Clearly x^* defines a permutation of F .

The following theorem holds.

THEOREM 1. *Every transposition $(\alpha\beta)$, where $\alpha, \beta \in F$ is finitely generated by the special permutations*

$$(3) \quad x^*, \quad \gamma x + \delta \quad (\gamma, \delta \in F, \gamma \neq 0).$$

The proof (compare [1]) follows from consideration of the function

$$g(x) = -\alpha^2 \left(\left((x - \alpha)^* + \frac{1}{\alpha} \right)^* - \alpha \right)^*,$$

where α is a fixed nonzero number of F . It is easily verified that $g(x)$ represents the transposition (0α) .

Let $G = G(F)$ denote the group consisting of all finite products

$$t_1 t_2 \cdots t_n,$$

where the t_j are arbitrary transpositions $(\alpha\beta)$. As an immediate corollary of Theorem 1 we have

THEOREM 2. *The group G is generated by the special permutations (3).*
