HOLOMORPHICITY OF A CLASS OF SEMIGROUPS OF MEASURES OPERATING ON $L^p(G/H)$

TOMASZ PRZEBINDA

ABSTRACT. In the present paper we consider the class of stable semigroups of measures on a Lie group G . This class contains the Gaussian semigroups. We prove that under certain strongly continuous representations of G acting in $L^p(G/H)$, $1 \leq p < \infty$, these semigroups are holomorphic and uniformly bounded.

Introduction. For a fixed Lie group G , let (S) denote the smallest family of semigroups of measures in G that contains all Gaussian semigroups (i.e., those semigroups whose infinitesimal generators are sub-Laplacians) and is closed with respect to taking sums of generators and subordination. Hulanicki [2] has posed the problem of determining if semigroups in (S) are holomorphic. It is known that Gaussian semigroups are holomorphic [5], but beyond this, additional assumptions are needed. For example, if G is a class two nilpotent group, any semigroup in (S) with L^2 densities is holomorphic [3]. In this paper we consider semigroups in the image of (S) under strongly continuous representations of G , and show that, for a certain class of representations, these semigroups are holomorphic.

Preliminaries. We identify the Lie algebra of G , $\mathfrak{g}$, with left-invariant differential operators by setting

$$Xf(x) = \frac{d}{dt} f(\exp tX) \big|_{t=0}.$$

For fixed basis $\{X_1, \dots, X_n\}$ of $\mathfrak{g}$ and multi-index $\mathbf{z} = (z_1, \dots, z_n)$ we set $|\mathbf{z}| = z_1 + \dots + z_n$ and

$$X^{\mathbf{z}}f = X_1^{z_1} \dots X_n^{z_n}f.$$

We denote by $C_0(G)$ the space of continuous real-valued functions on G that vanish at infinity, and for a positive integer k we set

$$C_0^k = \{f \in C_0(G) \mid X^{\mathbf{z}}f \in C_0 \text{ for } |\mathbf{z}| \leq k\}.$$

$C_0(G)$ is given the topology of uniform convergence, and $C_0^k(G)$, the topology of uniform convergence for derivatives of order k .

We identify $C_0(G)^*$ with $M(G)$, the space of bounded, regular Borel measures on G . $M(G)$ is a Banach $*$ -algebra with respect to convolution $\mu * \nu$, defined by

$$\langle \mu * \nu, F \rangle = \int_G \int_G F(xy) d\mu(x) d\nu(y),$$

and involution μ^* , defined by

$$\langle \mu^*, F \rangle = \int_G F(x^{-1}) d\mu(x).$$

We let $P(G)$ denote the subalgebra of nonnegative measures with norm ≤ 1 . A subset $\{\mu_t\}_{t \geq 0} \subseteq P(G)$ is said to be a *semigroup of measures on G* if $\mu_s * \mu_t = \mu_{s+t}$ and

$$\lim_{t \rightarrow 0} \|\mu_t * f - f\|_\infty = 0, \quad f \in C_0(G).$$

We denote by $C_c^\infty(G)$ the space of test functions on G , and by $\mathcal{D}'(G)$ the space of distributions on G . A distribution D is said to be *dissipative* if $\langle D, f \rangle \leq 0$ whenever $f \in C_c^\infty(G)$ and $f(e) = \|f\|_\infty$.

Given a semigroup of measures on G , $\{\mu_t\}_{t \geq 0}$, the *infinitesimal generator* of $\{\mu_t\}_{t \geq 0}$, A , is the closed operator on $C_0(G)$ defined by

$$Af = \lim_{t \downarrow 0} \frac{1}{t} (\mu_t * f - f),$$

where the domain $D(A)$ of A is the subset of $C_0(G)$ for which the right-hand side exists. One has that $C_c^\infty(G) \subseteq D(A)$ and that the mapping $f \mapsto Af(e)$ is a dissipative distribution on G . Conversely, given a dissipative distribution D on G , define the operator A_D on $C_c^\infty(G)$ by $A_D f(x) = \langle D, f_x \rangle$. Then A_D is closable in $C_0(G)$ and is the infinitesimal generator of a unique semigroup of measures on G . (These results are essentially due to Hunt [4], with more modern treatments found in [1 and 2].)

Let $\{\mu_t\}_{t \geq 0}$ and $\{\nu_t\}_{t \geq 0}$ be semigroups of measures on G with infinitesimal generators A and B , respectively. Clearly, $f \mapsto (A + B)f(e)$ is a dissipative distribution, and hence there is a unique semigroup whose infinitesimal generator on $C_c^\infty(G)$ is $A + B$. Also, given $0 < a < 1$, the distribution

$$f \mapsto -\Gamma(-a)^{-1} \int_0^\infty t^{-a-1} (\mu_t * f - f)(e) dt$$

is dissipative. We denote the corresponding semigroup of measures by $\{\mu_t^{(a)}\}_{t \geq 0}$ and its infinitesimal generator by $|A|^a$. $\{\mu_t^{(a)}\}_{t \geq 0}$ is said to be *subordinate* to $\{\mu_t\}_{t \geq 0}$.

Given a subset $\{X_1, \dots, X_k\} \subseteq \mathfrak{g}$, $f \mapsto (X_1^2 + \dots + X_k^2)f(e)$ is a dissipative distribution. Such distributions generate the *Gaussian semigroups*. The family of *stable* semigroups, (S) , consists of those semigroups of measures whose corresponding dissipative distribution belongs to $S(\mathfrak{g}) = \bigcup_{k=0}^\infty S_k(\mathfrak{g})$, where

$$\begin{aligned} S_0(\mathfrak{g}) &= \{f \mapsto X^2 f(e) \mid X \in \mathfrak{g}\}, \\ S_{2k}(\mathfrak{g}) &= \{D_1 + D_2 \mid D_i \in S_{2k-1}(\mathfrak{g})\} \cup S_{2k-1}(\mathfrak{g}) \end{aligned}$$

and

$$S_{2k+1}(\mathfrak{g}) = \{f \rightarrow -1 \mid A \mid f(e) \mid f \rightarrow Af(e) \in S_{2k}(\mathfrak{g})\} \cup S_{2k}(\mathfrak{g})$$

for $k = 1, 2, \dots$. For $D \in S(\mathfrak{g})$, the hull of D is the smallest Lie subalgebra of $\mathfrak{g}$, $\mathfrak{h}$, such that $D \in S(\mathfrak{h})$.

Holomorphicity of represented semigroups.

THEOREM 1. *Let $\{\mu_t\}_{t>0}$ be a stable semigroup of measures on G whose corresponding dissipative distribution has hull $\mathfrak{g}$ as above. There exists a $0 < \theta \leq \pi/2$, a positive integer p , and a family of holomorphic functions $\{\omega_n \mid n \in (\mathbb{Z}^+)^p\}$ defined on $\Omega_\theta = \{Z \in \mathbb{C} \mid |\arg Z| < \theta\}$ with values in $M(G)$ satisfying*

- (i) $\omega_n(t) \geq 0$ and $\|\omega_n(t)\| = 1$, for $t > 0$,
- (ii) $\lim_{n_1 \rightarrow \infty} \dots \lim_{n_p \rightarrow \infty} \omega_n(t) * f = \mu_t * f$ for $t > 0, f \in L^1(G)$,
- (iii) there is an $n_0 \in \mathbb{Z}^+$ such that for $n_i \geq n_0, 1 \leq i \leq p$, and $z \in \Omega_\theta, \omega_{(n_1, \dots, n_p)}(z) \in L^1(G)$.

PROOF. The proof is by induction on the smallest integer k such that dissipative distribution D corresponding to $\{\mu_t\}_{t>0}$ is in $S_k(\mathfrak{g})$. If $k = 0$ then $\dim(\mathfrak{g}) = 1$ and the theorem follows from well-known facts about the Gaussian semigroup on $\mathbb{R}$ or $\mathbb{T}$. For example, on $\mathbb{R}$ we take $\theta = \pi/2, p = 1$ and for $z \in \Omega_\theta, n \in \mathbb{Z}^+$, we have $\omega_n(z) = \omega_1(z) = (4\pi z)^{1/2} e^{-z^2/4z} dx$, where dx is Lebesgue measure on $\mathbb{R}$.

We assume the theorem for $j < 2k + 1$ and let $D \in S_{2k+1}(\mathfrak{g})$. There is a $D_1 \in S_{2k}(\mathfrak{g})$ and a $0 < a < 1$ so that $\mu_t = \nu_t^{(a)}$ where $\{\nu_t\}_{t>0}$ is generated by D_1 . Now, the hull of D_1 is $\mathfrak{g}$, and hence, by induction there exist, θ_1, p_1 and $\{\omega_n^1 \mid n \in (\mathbb{Z}^+)^{p_1}\}$ satisfying the conditions of the theorem. We let $\theta = a\theta_1, p = p_1$, and for $z \in \Omega_\theta, n \in (\mathbb{Z}^+)^p$, we define

$$\omega_n(z) = \int_0^\infty f_a(\lambda) \omega_n^1(\lambda z^{1/a}) d\lambda,$$

where

$$f_a(\lambda) = \frac{1}{2\pi i} \int_{\sigma-i\infty}^{\sigma+i\infty} e^{z\lambda - z^a} dz, \quad \sigma > 0, \lambda \geq 0.$$

Conditions (i) and (ii) then follow immediately from the properties of f_a and for (ii) we have, for $t > 0$ and $f \in L^1(G)$,

$$\begin{aligned} \lim_{n_1 \rightarrow \infty} \dots \lim_{n_p \rightarrow \infty} \omega_n(t) * f &= \lim_{n_1 \rightarrow \infty} \dots \lim_{n_p \rightarrow \infty} \int_0^\infty f_a(\lambda) \omega_n^1(\lambda t^{1/a}) * f d\lambda \\ &= \int_0^\infty f_a(\lambda) \nu_{\lambda t^{1/a}} * f d\lambda = \lambda_t^{(a)} * f. \end{aligned}$$

(The reader is referred to [8], for properties of f_a .)

Finally, we assume the theorem for $j < 2k$ and let $D \in S_{2k}(\mathfrak{g})$. Let $D_1, D_2 \in S_{2k-1}(\mathfrak{g})$ such that $D = D_1 + D_2$. Let $\mathfrak{g}_i$ be the hull of D_i and let G_i be the

corresponding connected Lie subgroups of G . (Note that $\mathfrak{g}$ is generated by $\mathfrak{g}_1$ and $\mathfrak{g}_2$.) There exist θ_i , p_i , and ω_n^i for $\mathbf{n} \in (\mathbb{Z}^+)^{p_i}$ satisfying the conditions of the theorem with respect to G_i . Let $\theta = \min\{\theta_1, \theta_2\}$, $p = p_1 + p_2 + 1$, and for $z \in \Omega_\theta$, $\mathbf{n} \in (\mathbb{Z}^+)^p$ let

$$\omega_{\mathbf{n}}(z) = \left(\omega_{n^1}^1(z/n_p) * \omega_{n^2}^2(z/n_p) \right)^{n_r},$$

where $\mathbf{n} = (n^1, n^2, n_p)$. $\omega_{\mathbf{n}}$ is holomorphic on Ω_θ and satisfies (i). Furthermore, if $\{\mu_t^i\}_{t>0}$ is the semigroup generated by D_i , then, for $f \in L^1(G)$, $t > 0$, one has, by Chernoff's theorem, that

$$\begin{aligned} \lim_{n_1 \rightarrow \infty} \cdots \lim_{n_p \rightarrow \infty} \omega_{\mathbf{n}}(t) * f &= \lim_{n_1 \rightarrow \infty} \cdots \lim_{n_p \rightarrow \infty} \left(\omega_{n^1}^1(t/n_p) * \omega_{n^2}^2(t/n_p) \right)^{n_r} * f \\ &= \lim_{n_p \rightarrow \infty} \left(\mu_{t/n_p}^1 * \mu_{t/n_p}^2 \right)^{n_p} * f = \mu_t * f. \end{aligned}$$

Condition (iii) is an immediate consequence of a known theorem:¹ Let $G_1, \dots, G_k$ be connected Lie subgroups of the Lie group G whose Lie algebras generate the Lie algebra of G . There is an integer N such that

$$(L^1(G_1) * L^1(G_2) * \cdots * L^1(G_k))^N \subseteq L^1(G).$$

Let H be a closed subgroup of the connected Lie group G and suppose there is a measure on G/H that is invariant with respect to the action of G . Suppose further that $\gamma: G \times G/H \rightarrow \mathbb{C}$ is a continuous function with $\|\gamma\|_\infty \leq 1$ such that, for $1 \leq p < \infty$, the mapping $y \rightarrow \Gamma_y^p$ of G into the bounded operators on $L^p(G/H)$ given by

$$\Gamma_y^p F(\dot{x}) = \gamma(y, \dot{x}) F(y^{-1}\dot{x})$$

for $F \in L^p(G/H)$ and a.e. $\dot{x} \in G/H$ defines a strongly continuous representation of G that is unitary for $p = 2$.

THEOREM 2. Let G be a connected Lie group, let $\{\mu_t\}_{t>0} \in (S)$, and suppose that the hull of the distribution generating $\{\mu_t\}_{t>0}$ is the Lie algebra of G . Let H and γ be as above and suppose that $\Gamma^p(L^1(G))$ is contained in the space of compact operators on $L^p(G/H)$ for $1 \leq p < \infty$. There is a $0 < \theta \leq \pi/2$ and a holomorphic $T^p: \Omega_\theta \rightarrow B(L^p(G/H))$ such that

- (i) $\sup\{\|T_z^p\| \mid z \in \Omega_\theta\} \leq 1$,
- (ii) for $t > 0$, $T_t^p = \Gamma^p(\mu_t)$.

PROOF. Let θ , p and ω_n be as in Theorem 1. Notice that $\omega_1(t)$ is the semigroup of probabilistic measures generated by X_1^2 , whose image $\Gamma^2(X_1^2) = A_1$ is an essentially selfadjoint operator [1, Theorem 12, Example 4] and generates the semigroup of contractions $\Gamma^2(\omega_1(t))$, so that

$$\Gamma^2(\omega_1(z)) = \int_{-\infty}^0 e^{\lambda z} dP(\lambda)$$

¹See remarks.

where P is the spectral measure of A_1 , and hence $\|\Gamma^2(\omega_1(z))\| \leq 1$ for $\operatorname{Re}(z) > 0$. Now by an induction argument analogous to that used in the proof of Theorem 1, one can show that for, $f \in L^p(G/H)$, $1 \leq p$ and $t > 0$,

$$\lim_{n_1 \rightarrow \infty} \cdots \lim_{n_p \rightarrow \infty} \Gamma^p(\omega_n(t))f = \Gamma^p(\mu_t)f$$

and that $\|\Gamma^2(\omega_n(z))\| \leq 1$ for $z \in \Omega_\theta$.

Let n_0 be as in Theorem 1, and set $\mathbf{Z}_0 = \{k \in \mathbf{Z}, k > n_0\}$. Then if $\mathbf{n} \in (\mathbf{Z}_0)^p$, $\omega_n(z) \in L^1(G)$ for $z \in \Omega_\theta$, and so $\Gamma^p(\omega_n(z))$ and $\Gamma^2(\omega_n(z))$ are compact operators. By [6], their spectra coincide, and hence also their norms. Thus $\|\Gamma^p(\omega_n(z))\| \leq 1$. Therefore, $\{\Gamma^p(\omega_n) \mid \mathbf{n} \in (\mathbf{Z}_0)^p\}$ is a family of holomorphic functions on Ω_θ that is uniformly bounded and convergent on $\mathbf{R}^+$. Thus, by Vitali's theorem,

$$\lim_{n_1 \rightarrow \infty} \cdots \lim_{n_p \rightarrow \infty} \Gamma^p(\omega_n(z)) = T_z^p$$

exists for $z \in \Omega_\theta$, and $z \mapsto T_z^p$ is holomorphic.

Remarks. 1. I have learned from Joe W. Jenkins and Andrzej Hulanicki that the theorem mentioned at the end of the proof of Theorem 1 was known but I could not find it in the literature. Here is a rough outline of a proof.

Assume for simplicity that $k = 2$. Using the fact that the zero set of a nontrivial real analytic function defined on an open subset of $\mathbf{R}^n$ has Lebesgue measure zero, one can prove the following:

LEMMA. Let M and G be two real analytic manifolds of dimensions N and n respectively ($N \geq n$), with Lebesgue measures μ and ν . Suppose that M is connected. If $F: M \rightarrow G$ is a real analytic function whose derivative has rank n at a point in M , then $F(\mu)$ is absolutely continuous with respect to ν .

Let $\mathfrak{g}_i$ be the Lie algebra of G_i with basis $\{X_{i1}, X_{i2}, \dots, X_{ip_i}\}$ ($i = 1, 2$). Let $\mathfrak{N}^0 = \{X_{11}, \dots, X_{1p_1}, X_{21}, \dots, X_{2p_2}\}$ and let $\mathfrak{N}^p = \mathfrak{N}^{p-1} \cup [\mathfrak{N}^{p-1}, \mathfrak{N}^{p-1}]$ for $p = 1, 2, 3, \dots$. The assumption that $\mathfrak{g}_1 \cup \mathfrak{g}_2$ generates $\mathfrak{g}$ implies that there is such a p that $\mathfrak{N}^p$ contains the basis $\{X_1, X_2, \dots, X_n\}$ of $\mathfrak{g}$. The Baker-Campbell-Hausdorff formula [7, Theorem 2.15.4] implies that there exists an m such that for every $X \in \mathfrak{N}^p$ there is a function $S_X: \mathbf{R} \rightarrow \mathbf{R}^{m(p_1+p_2)}$ such that for $|t|$ small enough we have $f_m(S_X(t)) = \exp(tX + r_X(t))$, where

$$\begin{aligned} f_m(u_{111}, u_{112}, \dots, u_{11p_1}, u_{121}, u_{122}, \dots, u_{12p_2}, \dots, u_{m11}, \\ \dots, u_{m12}, \dots, u_{m1p_1}, u_{m21}, u_{m22}, \dots, u_{m2p_2}) \\ = \exp\left(\sum_{j=1}^{p_1} u_{11j} X_{1j}\right) \exp\left(\sum_{j=1}^{p_2} u_{12j} X_{2j}\right) \cdots \exp\left(\sum_{j=1}^{p_1} u_{m1j} X_{1j}\right) \exp\left(\sum_{j=1}^{p_2} u_{m2j} X_{2j}\right) \end{aligned}$$

and

$$r_X(t) = \sum_{\alpha + \beta \geq 2^p} |t|^{(\alpha + \beta)/2^p} (\operatorname{sign}(t))^{\epsilon_{\alpha\beta}} X_{\alpha\beta} \quad (X_{\alpha\beta} \in \mathfrak{g}, \epsilon_{\alpha\beta} \in \{0, 1\}).$$

For example, if $p_1 = p_2 = 1$ and $X = [X_{11}, X_{21}]$ then $m = 2$ and

$$S_X(t) = (|t|^{1/2}, |t|^{1/2} \operatorname{sign}(t), -|t|^{1/2}, -|t|^{1/2} \operatorname{sign}(t)).$$

Choose S_{X_i} as above for every vector X_i from the basis of $\mathfrak{g}$, and put $S(\mathbf{t}) = S(t_1, t_2, \dots, t_n) = (S_{X_1}(t_1), S_{X_2}(t_2), \dots, S_{X_n}(t_n)) \in \mathbf{R}^{N(p_1+p_2)}$ where $N = nm$. Define $M = G_1 \times G_2 \times \dots \times G_1 \times G_2$ (N times).

$M \ni (x_{11}, x_{12}, \dots, x_{N1}, x_{N2}) \rightarrow F(x_{11}, x_{12}, \dots, x_{N1}, x_{N2}) = x_{11}x_{12} \dots x_{N1}x_{N2} \in G$ and $\Psi: \mathbf{R}^{N(p_1+p_2)} \rightarrow M$ by the formula

$$\begin{aligned} \Psi(u_{111}, u_{112}, \dots, u_{11p_1}, u_{121}, u_{122}, \dots, u_{12p_2}, \dots, u_{N11}, \\ u_{N12}, \dots, u_{N1p_1}, u_{N21}, u_{N22}, \dots, u_{N2p_2}) \\ = \left(\exp \left(\sum_{j=1}^{p_1} u_{11j} X_{1j} \right), \exp \left(\sum_{j=1}^{p_2} u_{12j} X_{2j} \right), \dots, \right. \\ \left. \exp \left(\sum_{j=1}^{p_1} u_{N1j} X_{1j} \right), \exp \left(\sum_{j=1}^{p_2} u_{N2j} X_{2j} \right) \right). \end{aligned}$$

Thus

$$\begin{aligned} F \circ \Psi \circ S(\mathbf{t}) &= f_m(S_{X_1}(t_1)) f_m(S_{X_2}(t_2)) \dots f_m(S_{X_n}(t_n)) \\ &= \exp(t_1 X_1 + r_{X_1}(t_1)) \exp(t_2 X_2 + r_{X_2}(t_2)) \dots \exp(t_n X_n + r_{X_n}(t_n)) \end{aligned}$$

in a neighborhood of the origin in $\mathbf{R}^n$, which implies that the Jacobian J of the map $F \circ \Psi \circ S$ is equal to the identity at $\mathbf{t} = 0$ and that there exists a neighborhood U of the origin in $\mathbf{R}^n$ such that for $\mathbf{t} \in U$, $J(\mathbf{t}) \neq 0$. Take $\mathbf{t}$ from U such that $t_i \neq 0$ for each $i = 1, 2, 3, \dots, n$. Then

$$\begin{aligned} n &= \operatorname{rank}(T_{\mathbf{t}}(F \circ \Psi \circ S)) = \operatorname{rank}(T(F)_{\Psi(S(\mathbf{t}))} \circ T_{\mathbf{t}}(\Psi \circ S)) \\ &\leq \operatorname{rank}(T(F)_{\Psi(S(\mathbf{t}))}) \leq n, \end{aligned}$$

so $\operatorname{rank}(T(F)_{\Psi(S(\mathbf{t}))}) = n$. By the lemma $F(\mu_1 \times \mu_2 \times \dots \times \mu_1 \times \mu_2)$ is absolutely continuous with respect to the Haar measure ν on G , i.e.

$$(\mu_1 * \mu_2)^N(E) = \mu_1 \times \mu_2 \times \dots \times \mu_1 \times \mu_2(F^{-1}(E)) = 0$$

for every set E with $\nu(E) = 0$.

2. Theorem 2 gives only a partial answer to Hulanicki's question: determine if semigroups in (S) are holomorphic. The proof and the boundedness of $\|T_z^p\|$ for $z \in \Omega_\theta$ depend very much on the assumption that those operators are compact. Suppose G is a locally compact group and H is a subgroup of G such that there exists an invariant measure on G/H . Moreover assume that $\gamma = 1$ and G/H is not compact. Then one can show [6] that if $f \in L^1(G)$ and $\int_G f(y) dy \neq 0$ it follows that $\Gamma^p(f)$ is not compact in any $L^p(G/H)$, $1 \leq p < \infty$. The reader who is interested in the importance of having the semigroups holomorphic on all L^p spaces, $1 \leq p < \infty$, is referred to [2].

The author is very grateful to Joe W. Jenkins for many simplifications and corrections in this paper and to Romuald Dabrowski, Pawel Glowacki, Andrzej Hulanicki, and Czelsaw Ryll-Nardzewski for many discussions on the subject.
