# LOMONOSOV'S INVARIANT SUBSPACE THEOREM FOR MULTIVALUED LINEAR OPERATORS 

PETER SAVELIEV<br>(Communicated by Joseph A. Ball)

#### Abstract

The famous Lomonosov's invariant subspace theorem states that if a continuous linear operator $T$ on an infinite-dimensional normed space $E$ "commutes" with a compact operator $K \neq 0$, i.e., $T K=K T$, then $T$ has a non-trivial closed invariant subspace. We generalize this theorem for multivalued linear operators. We also provide an application to single-valued linear operators.

## 1. Introduction

The Invariant Subspace Problem asks whether every linear operator $h: Y \rightarrow$ $Y$ on an infinite dimensional topological vector space $Y$ has a nontrivial closed invariant subspace, i.e., a linear subspace $M$ of $Y$ such that $M \neq\{0\}, M \neq Y$ and $h(M) \subset M$ (for a survey and references see [6, [1). In general the answer is negative and the issue is to investigate the class of operators satisfying this property. It is known that every compact operator $k$ belongs to this class and so does every operator $h$ commuting with $k$ :

$$
h k=k h .
$$

The famous Lomonosov's invariant subspace theorem [5] states the following.
Theorem 1.1. Suppose $Y$ is an infinite dimensional normed space, and $h$ and $k$ are continuous linear operators, where $k$ is compact, nonzero and commutes with $h$. Then $h$ has a nontrivial closed invariant subspace.

In this paper we generalize this result for multivalued linear operators. The theory of multivalued linear operators (linear relations) is well developed; see Cross [2]. A multivalued map $h: X \rightarrow Y$ between vector spaces is called a linear relation if

$$
h(a x)=a h(x), \quad h(x+y)=h(x)+h(y)
$$

for all $x, y \in X$ and all $a \neq 0$. We say that $h, k: Y \rightarrow Y$ commute if

$$
h k \subset k h .
$$

[^0]For a linear relation $h: Y \rightarrow Y$, a subspace $M$ of $Y$ is called $h$-weakly-invariant if for all $x \in M$

$$
h(x) \cap M \neq \emptyset .
$$

The idea of the proof of our main theorem below (Corollary6.5) can be traced back to the original Lomonosov's proof.

Theorem 1.2. Suppose $Y$ is an infinite dimensional normed topological vector space, and $h$ and $k$ are continuous linear relations with nonempty finite dimensional values, where $k$ is compact and commutes with $h$ and $k^{-1}(0) \neq Y$. Then there is a nontrivial closed $h$-weakly-invariant subspace.

We consider only the right commutativity; the problem for the left commutativity, $k h \subset h k$, remains open.

Invariant subspace theorems for linear relations provide tools for studying the Invariant Subspace Problem for single valued linear operators. We consider those in the last section.

All topological spaces are assumed to be Hausdorff, all maps are multivalued with nonempty values unless indicated otherwise, and by normed (locally convex) spaces we understand infinite dimensional normed (locally convex) topological vector spaces over $\mathbf{C}$ or $\mathbf{R}$.

## 2. Preliminaries

Let $X$ be a topological space. The partition of unity is a collection of continuous functions $\gamma=\left\{d_{\alpha}: \alpha \in A\right\}$ satisfying

$$
\sum_{\alpha \in A} d_{\alpha}(x)=1, x \in X
$$

The partition $\gamma$ is called locally finite if the cover $\gamma^{\prime}=\left\{d_{\alpha}^{-1}((0,1]): \alpha \in A\right\}$ of $X$ is locally finite, and $\gamma$ is called subordinate to an open cover $\omega$ of $X$ if $\gamma^{\prime}$ refines $\omega$.

Let $F: X \rightarrow Y$ be a multifunction (a set-valued map $F: X \rightarrow 2^{Y}$ ), where $X, Y$ are topological spaces. We call $F$ lower-semicontinuous (l.s.c.) if $F^{-1}(B)=$ $\{x \in X: F(x) \cap B \neq \emptyset\}$ is open for any open $B$. We call $F$ upper-semicontinuous (u.s.c.) if $F^{-1}(B)$ is closed for any closed $B$. Equivalently, for any $x \in X$ and a neighborhood $V$ of $F(x)$, there is a neighborhood $U$ of $x$ such that

$$
y \in U \Longrightarrow F(y) \subset V
$$

If $F$ is both u.s.c. and l.s.c. we call it continuous (in [2] "continuous" means l.s.c.). When $X$ and $Y$ are uniform spaces [3, Chapter 8] we say that $F$ is uniformly uppersemicontinuous (u.u.s.c.) if for any entourage $V$ in $Y$ there is an entourage $U$ in $X$, such that for all $x, y \in X$,

$$
x \in y+U \Longrightarrow F(x) \subset F(y)+V
$$

We say that $x \in X$ is a fixed point of $F: X \rightarrow X$ if $x \in F(x)$. We say that a single-valued function $g: X \rightarrow Y$ is a selection of $F: X \rightarrow Y$ if $g(x) \in F(x)$ for all $x \in X$.

A topological space is called acyclic if its reduced Čech homology groups over the rationals are trivial. In particular, convex subsets of locally convex spaces are acyclic. A multivalued map $F: X \rightarrow Y$ is called admissible (in the sense of Gorniewicz [4]) if it is closed valued u.s.c. and there exist a topological space $Z$
and two single-valued continuous maps $p: Z \rightarrow X, q: Z \rightarrow Y$ such that for any $x \in X$, (i) $p^{-1}(x)$ is acyclic, and (ii) $q\left(p^{-1}(x)\right) \subset F(x)$.

Proposition 2.1 ([4] Theorem IV.40.5, p. 200]). The composition of two admissible maps is admissible.

In the proof of his theorem Lomonosov used the Schauder fixed point theorem. Here we need its analogue for multivalued maps. We use a result that follows from the Lefschetz fixed point theory for admissible maps given in 4] (for further developments see (7), although an appropriate version of the Kakutani fixed point theorem for compositions of convex valued maps would suffice.

Theorem 2.2 ([4, Theorem IV.41.12, p. 207]). If $X$ is an acycic ANR, then $X$ has the fixed point property within the class of compact (i.e., with $\overline{f(X)}$ compact) admissible maps, in particular, for u.s.c. maps with compact acyclic values.

## 3. Approximation by convex combinations

In this section we consider the approximations of multivalued maps by convex combinations in the spirit of Simonič [8, 9].

Let $X$ be a topological space, $Y$ a vector space and $H$ a collection of multivalued maps $h: X \rightarrow Y$. Given a partition of unity $\gamma=\left\{d_{\alpha}: \alpha \in A\right\}$ in $X$, for any collection $\left\{h_{\alpha}: \alpha \in A\right\} \subset H$, we can define a new map $h: X \rightarrow Y$ by

$$
\begin{equation*}
h(x)=\sum_{\alpha \in A} d_{\alpha}(x) h_{\alpha}(x) . \tag{3.1}
\end{equation*}
$$

The set of all such $h$ we denote by $\operatorname{Conv}_{\gamma}(H)$.
Let $\Delta_{n}$ denote the standard $n$-simplex. For any collection $h_{0}, \ldots, h_{n}$ and any $\left(t_{0}, \ldots, t_{n}\right) \in \Delta_{n}$, we define a new map $h: X \rightarrow Y$ by

$$
h(x)=\sum_{i=0}^{n} t_{i} h_{i}(x) .
$$

The set of all such $h$ we denote by $\operatorname{Conv}(H)$.
Remark 3.1. $H \subset \operatorname{Conv}(H) \subset \operatorname{Conv}_{\gamma}(H)$.
The following theorem generalizes Lemma 3.1 of Simonič 8].
Theorem 3.2 (Approximation). Let $X$ be a paracompact uniform space and $Y a$ locally convex space. Suppose $s: X \rightarrow Y$ is a u.u.s.c. map with convex values and $H$ is a collection of u.s.c. maps $h: X \rightarrow Y$. Suppose $V$ is a convex neighborhood of 0 in $Y$ and for any $x \in X$ there is $h_{x} \in H$ such that

$$
h_{x}(x) \subset s(x)+V
$$

Then there exist a locally finite partition of unity $\gamma$ on $X$ and a map $f \in \operatorname{Conv}_{\gamma}(H)$ such that for all $x \in X$,

$$
f(x) \subset s(x)+3 V
$$

Proof. From the upper semicontinuity it follows that for each $x \in X$ there is a $W_{x}$ such that for any $y \in W_{x}$,

$$
h_{x}(y) \subset h_{x}(x)+V \text { and } s(x) \subset s(y)+V
$$

Now applying these inclusions and the assumption of the theorem, we obtain the following: for any $y \in W_{x}$,

$$
h_{x}(y) \subset h_{x}(x)+V \subset s(x)+2 V \subset s(y)+3 V
$$

Consider the open cover of $X$ given by $\omega=\left\{W_{x}: x \in X\right\}$. From Michael's Lemma [3, Theorem 5.1.9, p. 301] it follows that there exists a locally finite partition of unity $\gamma=\left\{d_{\alpha}: \alpha \in A\right\}$ subordinate to $\omega$. Then we have a locally finite open cover of $X$

$$
\omega^{\prime}=\left\{U_{\alpha}=d_{\alpha}^{-1}((0,1]): \alpha \in A\right\}
$$

that refines $\omega$, i.e., for each $\alpha \in A$ there is $x(\alpha) \in X$ such that $U_{\alpha} \subset W_{x(\alpha)}$.
Fix $y \in X$. Suppose $\alpha \in A$ and $d_{\alpha}(y)>0$. Then $y \in U_{\alpha} \subset W_{x(\alpha)}$. Hence

$$
h_{x(\alpha)}(y) \subset s(y)+3 V
$$

As $s(y)$ and $V$ are convex, so is the set $s(y)+3 V$. Therefore a convex combination of $h_{x(\alpha)}(y), \alpha \in A$, is a well defined subset of $s(y)+3 V$. Then the map $f: X \rightarrow Y$ given by

$$
f(y)=\sum_{\alpha \in A} d_{\alpha}(y) h_{\alpha}(y)
$$

is well defined and belongs to $\operatorname{Conv}_{\gamma}(H)$.
Simonič calls $d_{\alpha}$ Lomonosov functions, as the idea of this construction goes back to Lomonosov's proof in [5]. Observe also that the above theorem implies the following well-known fact: any u.s.c. map with convex images from a compact metric space to a locally convex space can be approximated by continuous singlevalued maps.

## 4. Fixed points of convex combinations

In this section we obtain a preliminary fixed point result.
Proposition 4.1. Let $X$ be a topological space, $Y$ a vector space, $H$ a collection of maps $h: X \rightarrow Y, r: Y \rightarrow X$ a map, $\gamma$ a locally finite partition of unity on $X$, $f \in \operatorname{Conv}_{\gamma}(H)$, and suppose $\mathrm{fr}: Y \rightarrow Y$ has a fixed point $y_{0}$. Then there exists $g \in \operatorname{Conv}(H)$ such that $y_{0}$ is a fixed point of $g r$.

Proof. We know that $y_{0} \in \operatorname{fr}\left(y_{0}\right)$. Let $Z=\operatorname{Graph}(r) \subset Y \times X, p: Z \rightarrow Y, q: Z \rightarrow$ $X$ be the projections. Then there is $z_{0} \in Z$ such that $y_{0}=p\left(z_{0}\right) \in f q\left(z_{0}\right)$. Assume that $\gamma=\left\{d_{\alpha}: \alpha \in A\right\}$ and suppose

$$
f(x)=\sum_{\alpha \in A} d_{\alpha}(x) h_{\alpha}(x)
$$

where $h_{\alpha} \in H$. Let $x_{0}=q\left(z_{0}\right)$. Suppose $\left\{\alpha \in A: d_{\alpha}\left(x_{0}\right)>0\right\}=\left\{\alpha_{0}, \ldots, \alpha_{n}\right\}, n \geq 0$. For $i=0, \ldots, n$, let

$$
t_{i}=d_{\alpha_{i}}\left(x_{0}\right), h_{i}=h_{\alpha_{i}}
$$

Then $y_{0} \in f q\left(z_{0}\right)=f\left(x_{0}\right)=\sum_{i=0}^{n} t_{i} h_{i}\left(x_{0}\right)$. We have an element of $\operatorname{Conv}(H)$ :

$$
g(x)=\sum_{i=0}^{n} t_{i} h_{i}(x), x \in X
$$

Consider

$$
\begin{aligned}
g q\left(z_{0}\right) & =\sum_{i=0}^{n} t_{i} h_{i}\left(q\left(z_{0}\right)\right) \\
& =\sum_{i=0}^{n} d_{\alpha_{i}}\left(x_{0}\right) h_{i}\left(q\left(z_{0}\right)\right) \\
& =\sum_{\alpha \in A} d_{\alpha_{i}}\left(q\left(z_{0}\right)\right) h_{i}\left(q\left(z_{0}\right)\right) \\
& =f q\left(z_{0}\right) \\
& \ni p\left(z_{0}\right)=y_{0}
\end{aligned}
$$

Thus $y_{0}$ is a fixed point of $g r$.
If $Y$ is a topological vector space, we denote by $F_{c}(X, Y)$ the set of all u.s.c. maps $F: X \rightarrow Y$ with compact convex values. Then all elements of $F_{c}(X, Y)$ are admissible provided $Y$ is locally convex.
Lemma 4.2. $\operatorname{Conv}_{\gamma}\left(F_{c}(X, Y)\right) \subset F_{c}(X, Y)$.
Theorem 4.3 (Fixed points). Let $Y$ be a locally convex space, $A \subset Y$ closed convex, $U$ a closed neighborhood of $A$, and $X$ a paracompact uniform space. Let $r \in F_{c}(U, X), \overline{r(U)}$ compact, $H \subset F_{c}(X, Y)$, and

$$
\overline{H(x)} \cap A \neq \emptyset, \text { for all } x \in X
$$

Then for any neighborhood $W$ of $A, \operatorname{Conv}(H) r$ has a fixed point in $W$.
Proof. Assume that there is a convex neighborhood $V$ of 0 such that $U=A+3 V \subset$ $W$ and for each $x \in X$, there is $h_{x} \in H$ such that $h_{x}(x) \cap(A+1 / 2 V) \neq \emptyset$. Now, for each $h \in H$, let

$$
h^{\prime}(x)=h(x) \cap \overline{(A+1 / 2 V)}
$$

and let $H^{\prime}=\left\{h^{\prime}: h \in H\right\}$. Then the set $h^{\prime}(x)$ is nonempty by assumption, convex since $Y$ is locally convex, compact as the intersection of a compact set and a closed set. Also $h^{\prime}$ is u.s.c. by [3, 1.7.17(c)]. Thus $h^{\prime} \in F_{c}(X, Y)$. Now we apply Theorem 3.2 with $s(x)=A$ for all $x$ (by definition $h_{x}^{\prime}(x) \subset s(x)+V$ ). Therefore there exists $f \in \operatorname{Conv}_{\gamma}\left(H^{\prime}\right)$ such that for all $x, f(x) \subset s(x)+3 V=U$. We know that $r, f$ are admissible. Therefore by Proposition 2.1, so is $\varphi=f r: U \rightarrow U$. Now $r$ is compact and $U$ is an ANR as a closed neighborhood in a locally convex space. Hence by Theorem 2.2. $\varphi$ has a fixed point $y_{0} \in U \subset W$. Therefore by Proposition 4.1, there exists $g \in \operatorname{Conv}(H)$ such that $y_{0}$ is a fixed point of $g r$.

## 5. Properties of linear relations

Throughout the rest of the paper we assume that $X$ and $Y$ are normed spaces.
Definition 5.1 ([2, II.1.3, p. 25]). A multivalued map $h: X \rightarrow Y$ is called a linear relation if it preserves nonzero linear combinations, i.e., for all $x, y \in X$ and all $a, b \in \mathbf{R} \backslash\{0\}$, we have

$$
h(a x+b y)=a h(x)+b h(y)
$$

Then $h(0)$ is a linear subspace. The set of all linear relations will be denoted by $L R(X, Y)$ and $L R(X, X)=L R(X)$.

Lemma 5.2 ([2, Proposition I.2.8, p. 7]). If $T \in L R(X, Y), x \in X$, then

$$
T(x)=y+T(0), \text { for any } y \in T(x)
$$

We will concentrate on the following classes of linear relations:

$$
\begin{aligned}
L R_{0}(X, Y) & =\{h \in L R(X, Y): h \text { is continuous, } \operatorname{dim} h(0)<\infty\} \\
L R_{0}(Y) & =L R_{0}(Y, Y)
\end{aligned}
$$

Of course, all bounded linear operators belong to $L R_{0}(X, Y)$.
For a linear relation $T \in L R_{0}(X, Y)$, let $Q_{T}$ denote the natural quotient map with domain $X$ and null space $T(0)$ [2] p. 25].

Lemma 5.3. If $S \in L R_{0}(X, Y), T \in L R_{0}(Y, Z)$, then $T S \in L R_{0}(X, Z)$.
Proof. $Q_{T} T: S(0) \rightarrow Z / T(0)$ is a linear operator, so $\operatorname{dim} Q_{T} T S(0)<\infty$. Now $\operatorname{dim} T(0)<\infty$ implies $\operatorname{dim} T S(0)<\infty$.

Definition 5.4 ([2]). A linear relation $T \in L R_{0}(X, Y)$ is called bounded (compact) if the single valued operator $Q_{T} T$ is bounded (compact), i.e., it maps a bounded set into a bounded (compact) set.

By Proposition II.3.2(a) in [2, p. 33], every element of $L R_{0}(X, Y)$ is bounded.
Lemma 5.5. $T \in L R_{0}(X, Y)$ is compact if and only if for any bounded $B \subset X$, there is a compact set $C \subset Y$ such that $T(B) \subset C+T(0)$. Moreover $C$ can be chosen such that $T(x) \cap C \neq \emptyset$ for all $x \in B$.

Proof. The "if" part is obvious. Next, if $Q_{T} T: X \rightarrow Z=Y / T(0)$ is a compact linear operator, then for any bounded $B \subset X$, there is a compact $D \subset Z$ such that $Q_{T} T(B) \subset D$. Now since $T(0)$ is a finite dimensional subspace of a normed space, it is topologically complemented, i.e., $Y$ is homeomorphic to $Z \oplus T(0)$. Then $C=D \oplus\{0\}$ is compact in $Y$ and $T(B) \subset C+T(0)$.

Theorem 5.6. Suppose $h \in L R_{0}(Y, Z)$ and $k \in L R_{0}(X, Y)$ is compact. Then $h k \in L R_{0}(X, Z)$ is compact.

Proof. Let $A$ be a bounded subset of $X$. Then by Lemma $5.5 k(A) \subset C+k(0)$, where $C$ is compact. Therefore $h k(A) \subset h(C)+h k(0)$. It is easy to show that there is a bounded set $D$ in $Z$ such that $h(C)=D+h(0)$. Let $h^{\prime}(x)=h(x) \cap \bar{D}$. Then $h^{\prime}(x)$ is compact as $h(x)$ is finite dimensional. In particular, $h^{\prime}(x)$ is closed, so by [3, 1.7.17(c)], $h^{\prime}=h \cap \bar{D}$ is u.s.c. Therefore $h(C) \cap \bar{D}=h^{\prime}(C)$ is compact in $Z$ by [4, Proposition II.14.9, p. 69]. But $D \subset h^{\prime}(C)$, hence $D$ is precompact. Thus

$$
h k(A) \subset h(C)+h k(0)=D+h(0)+h k(0)=D+h k(0),
$$

where $D$ is precompact, so $h k$ is compact by Lemma 5.5
Therefore compact relations constitute a left ideal in $L R_{0}(Y)$.
We call $G \subset L R(Y)$ a semialgebra if it is closed under nonzero linear combinations and compositions. Lemma 5.3 implies that $L R_{0}(Y)$ is a semialgebra.

We define the commutant of $h$ as

$$
\operatorname{Comm}(h)=\left\{f \in L R_{0}(Y): f \text { commutes with } h\right\}
$$

Lemma 5.7. If $h \in L R(Y)$, then $\operatorname{Comm}(h)$ is a semialgebra.
Proof. First, $\operatorname{Comm}(h)$ is closed under linear combinations. Indeed, for $f, f^{\prime} \in$ $\operatorname{Comm}(h)$ and $a, b \in \mathbf{R} \backslash\{\mathbf{0}\}$, we have

$$
h\left(a f+b f^{\prime}\right)=a h f+b h f^{\prime} \subset a f h+b f^{\prime} h=\left(a f+b f^{\prime}\right) h
$$

Second, if $f, g$ both commute with $h$, then $u=g f$ commutes with $h$. Indeed

$$
h u=h g f \subset g h f \subset g f h=u h
$$

## 6. Invariant subspaces of Linear relations

Lemma 6.1. Suppose $G \subset L R(Y)$ is a semialgebra. Then for any $u \in Y, G(u) \cup$ $\{0\}$ is a linear subspace of $Y$.

Proof. Let $x, y \in G(u)$. Then $x \in f(u), y \in f^{\prime}(u)$ for some $f, f^{\prime} \in G$. Suppose $a, b \in \mathbf{R} \backslash\{\mathbf{0}\}$ and let $g=a f+b f^{\prime} \in G$. Then

$$
a x+b y \in a f(u)+b f^{\prime}(u)=g(u) \subset G(u)
$$

Lemma 6.2. Suppose $R \in L R(Y)$. Then

$$
\operatorname{Fix}(R)=\{x \in Y: x \in R(x)\}
$$

is a linear subspace of $Y$.
Proof. Let $a, b \in \mathbf{R} \backslash\{0\}$ and $x, y \in \operatorname{Fix}(R)$. Then $a x+b y \in a R(x)+b R(y)=$ $R(a x+b y)$, so $a x+b y \in F i x(R)$.

Lemma 6.3. Suppose $h \in L R(Y), R \in \operatorname{Comm}(h)$ and $h(0) \subset R(0)$. Then $M=$ Fix $(R)$ is h-weakly-invariant.

Proof. Let $x \in M=\operatorname{Fix}(R)$. Then $A=h(x) \in h R(x) \subset R h(x)=R(A)$. In particular, there is some $z \in A$ such that $R(z) \cap A \neq \emptyset$. Suppose $y \in R(z) \cap A$. Now we use Lemma 5.2 as follows:

$$
z \in A=h(x)=y+h(0) \subset y+R(0)=R(z)
$$

Hence $z \in \operatorname{Fix}(R)=M$, so $h(x) \cap M \neq \emptyset$.
The main results of this paper are given below.
Theorem 6.4 (Weakly invariant subspaces). Suppose $Y$ is a normed space, $h \in$ $L R(Y), G \subset \operatorname{Comm}(h)$ is a semialgebra, $k \in \operatorname{Comm}(h)$ is compact and $k^{-1}(0) \neq Y$. Suppose that for all $g \in G, h(0) \subset g k(0)$. Then there exists a nontrivial closed linear subspace $M \subset Y$ such that
either (1) $M$ is $G$-invariant,
or (2) $M$ is finite-dimensional and $h$-weakly-invariant.
Proof. For each $u \in Y, G(u)$ is $G$-invariant. Indeed, suppose $x \in G(u)$ and $g \in G$. Then $x \in f(u)$ for some $f \in G$. Therefore $g f \in G$ and $g(x) \subset g f(u) \subset G(u)$. Suppose now that $Q=G\left(u_{0}\right)$ is not dense in $Y$ for some $u_{0} \in Y \backslash\{0\}$. Then
we can assume that $Q \neq\{0\}$, because otherwise $\operatorname{span}\left\{u_{0}\right\}$ is $G$-invariant. Then $M=\bar{Q}=\overline{Q \cup\{0\}}$ is the desired subspace. First, $L=Q \cup\{0\}$ is a linear subspace of $Y$ by Lemma 6.1 Second, since every $f \in G$ is u.s.c., $f(Q) \subset Q$ implies $f(\bar{Q}) \subset \bar{Q}$. Hence $M$ is $G$-invariant.

Assume now that $G(y)$ is dense in $Y$ for each $y \in Y \backslash\{0\}$. Since $k$ is u.s.c., $k^{-1}(0)$ is closed. Therefore we can choose a closed convex neighborhood $U \subset Y$ of some $b \in Y \backslash\{0\}$ such that $0 \notin U$ and $U \subset Y \backslash k^{-1}(0)$. In addition we have

$$
\begin{equation*}
b \in \overline{G(y)}, \text { for all } y \in Y \backslash\{0\} \tag{*}
\end{equation*}
$$

Now we apply Theorem 4.3 with $X=Y \backslash\{0\}, A=\{b\}$ as follows. We let $H=$ $\{g \cap U: g \in G\}$. Then $H \subset F_{c}(Y)$. We can also rewrite (*) as

$$
\overline{H(x)} \cap A \neq \emptyset, \text { for all } x \in Y \backslash\{0\}
$$

By Lemma 5.5, there is a compact $C \subset Y$ such that $k(x) \cap C \neq \emptyset$. Define $r \in$ $F_{c}(Y, Y)$ by $r(x)=k(x) \cap C$. Since $k$ is compact, $r(U)$ is precompact. Therefore by Theorem 4.3 for any neighborhood $W$ of $b, \operatorname{Conv}(H) r$ has a fixed point in $W$. Therefore there is $g \in \operatorname{Conv}(G) \subset G$ such that $R=g k$ has a fixed point $y_{0} \neq 0$. Thus

$$
M=F i x(R) \neq\{0\}
$$

Now $R \in \operatorname{Comm}(h)$ (Lemma 5.7), $M$ is a linear subspace of $Y$ (Lemma 6.2), and $M$ is $h$-invariant (Lemma 6.3).

Suppose now that $B \subset M$ is a bounded neighborhood of 0 . Since $R$ is compact by Theorem 5.6 we have $B \subset R(B) \subset C+R(0)$, where $C$ is compact and $R(0)$ is finite dimensional. Therefore $M$ is finite dimensional.

Corollary 6.5. Suppose $Y$ is a normed space, $h \in L R_{0}(Y), k \in \operatorname{Comm}(h)$ is compact, and $k^{-1}(0) \neq Y$. Then there exists a nontrivial closed $h$-weakly-invariant subspace $M \subset Y$.

Proof. Let

$$
G=\{P(h): P \text { is a polynomial without constant term }\}
$$

Then $G \subset \operatorname{Comm}(h)$ and $G$ is a semialgebra. To check the rest of the conditions of the theorem, observe that since $0 \in k(0)$, we have $h^{n}(0) \subset h^{n} k(0)$ for all $n \geq 0$. Therefore $h(0) \subset h^{n}(0) \subset h^{n} k(0)$ for all $n \geq 1$, so that $h(0) \subset P(h)(0)$ for any polynomial $P$ without constant term. Thus for all $g \in G, h(0) \subset g k(0)$. Therefore by the theorem there is a nontrivial closed linear subspace $M \subset Y$ which is either $G$-invariant or $h$-weakly-invariant. Since $h \in G, M$ is $h$-weakly-invariant.

Remark 6.6. If $h \in L R(Y)$, then $h(0)$ is a subspace of $Y$. However, it is not weakly invariant as the following simple example shows. Take $Y=\mathbf{R}^{2}, f: Y \rightarrow Y$ the rotation through $\pi / 2, N$ the $y$-axis, and $h(x)=f(x)+N$.

Remark 6.7. When both $h$ and $k$ are single valued, the corollary reduces to Lomonosov's Theorem 1.1. The corollary is vacuous when $h$ is single-valued while $k$ is not, because $h k \subset k h$ implies that $k(0)$ is a finite-dimensional $h$-invariant subspace. Yet in the next section we will obtain an application of Theorem 6.4 to linear operators.

## 7. Invariant subspaces of Linear operators

In this section we generalize a well known corollary to Lomonosov's Theorem 1.1.

Lemma 7.1. Suppose $h, k \in L R(Y)$. Then

$$
G=\{g \in \operatorname{Comm}(h): h(0) \subset g k(0)\}
$$

is a semialgebra.
Proof. By Lemma5.7 $\operatorname{Comm}(h)$ is a semialgebra, so we need only to consider the following: (1) Suppose $h(0) \subset f k(0)$ and $h(0) \subset g k(0), a, b \neq 0$. Then $h(0) \subset$ $a f k(0)+b g k(0)=(a f+b g) k(0)$ because $h(0)$ is a linear subspace. Thus $G$ is closed under nonzero linear combinations. (2) Suppose $h(0) \subset f k(0), g$ commutes with $h$. Now since $0 \in g(0)$, we have

$$
h(0) \subset h g(0) \subset g h(0) \subset g f k(0)
$$

Hence $G$ is closed under compositions.
Suppose $Y$ is a space over $\mathbf{C}$. Given $h \in L R(Y)$, its eigenvalue $\lambda \in \mathbf{C}$ and eigenvector $u \neq 0$ satisfy

$$
\lambda u \in h(u)
$$

(or $(\lambda I d-h)^{-1}(0) \neq\{0\}[2]$ p. 223]). The eigenspace of $h$ corresponding to $\lambda$ is given by

$$
E_{h \lambda}=\{u \in Y: \lambda u \in h(u)\}
$$

Lemma 7.2. If $h \in L R(Y)$ is u.s.c., then $E_{h \lambda}$ is a closed linear subspace.
Proof. The set $E_{h \lambda}=(\lambda I d-h)^{-1}(0)$ is closed because $h$ is u.s.c.
The next lemma follows from [2, Theorem V.3.3, p. 226].
Lemma 7.3. Let $E$ be a finite dimensional space over $\mathbf{C}$. Then any $h \in L R_{0}(E)$ has an eigenvector.

We say that the maps $h, k: Y \rightarrow Y$ strictly commute if

$$
k h=h k .
$$

Theorem 7.4 (Invariant subspaces). Let $Y$ be a normed space over $\mathbf{C}, h \in L R(Y)$ is u.s.c., for any $\lambda \in \mathbf{C}, \lambda I d$ is not a selection of $h, k \in \operatorname{Comm}(h)$ compact, and $k^{-1}(0) \neq Y$. If a linear operator $f: Y \rightarrow Y$ strictly commutes with $h$ and $h(0) \subset f k(0)$, then there is a nontrivial closed $f$-invariant subspace.
Proof. By Lemma 7.1

$$
G=\{g \in \operatorname{Comm}(h): h(0) \subset g k(0)\}
$$

is a semialgebra. Therefore by Theorem 6.4 there is a nontrivial closed subspace $M$ that is either (1) $G$-invariant or (2) finite-dimensional and $h$-weakly-invariant. In the case of (1) $M$ is $f$-invariant because $f \in G$. Consider (2). If $h^{\prime}=h \cap M: M \rightarrow$ $M$, then $h^{\prime}$ is a linear relation with nonempty values. Then by Lemma 7.3 $h^{\prime}$ has an eigenvector corresponding to some $\lambda \in \mathbf{C}$. Therefore the eigenspace $N=E_{h \lambda}$ is nonzero, closed, and not equal to the whole $Y$. Then for each $x \in N$, we have

$$
\lambda f(x)=f(\lambda x) \in f h(x)=h f(x)
$$

Hence $f(x) \in N$.

The following result involves only single valued operators.
Corollary 7.5. Let $Y$ be a normed space over $\mathbf{C}, N$ a finite dimensional subspace of $Y$, and $f, h, k: Y \rightarrow Y$ bounded linear operators. Suppose for any $\lambda \in \mathbf{C}$, $h \neq \lambda I d, k$ is nonzero compact. Suppose also that
(1) $f h=h f$,
(2) $h k-k h \in N$,
(3) $h(N) \subset N$.

Then there is a nontrivial closed $f$-invariant subspace.
Proof. Apply the above theorem to the linear relation $k+N$.
