(Communicated by Nigel J. Kalton)

ABSTRACT. We give a negative answer to a question of Prăjitură by showing that there exists an invertible bilateral weighted shift T on $\ell_2(\mathbb{Z})$ such that T and 3T are hypercyclic but 2T is not. Moreover, any G_{δ} set $M \subseteq (0, \infty)$ which is bounded and bounded away from zero can be realized as $M = \{t > 0 \mid tT \text{ is hypercyclic}\}$ for some invertible operator T acting on a Hilbert space.

1. Introduction

This note is devoted to the study of multiples of hypercyclic operators acting on a real or complex separable Banach space X. An operator $T \in \mathcal{B}(X)$ is said to be hypercyclic if there exists a vector $x \in X$ which has a dense orbit, i.e. the set $\{T^nx \mid n \geq 0\}$ is dense in X. Hypercyclic operators have been the subject of an active investigation in the past twenty years, and we refer the reader to the book [1] for a thorough survey of this area. The first examples of hypercyclic operators were given by Rolewicz in 1969: if B is the backward shift on $\ell_p(\mathbb{N})$, $1 \leq p < +\infty$, or $c_0(\mathbb{N})$, with the canonical basis $(e_n)_{n\geq 0}$, defined by $Be_0 = 0$ and $Be_n = e_{n-1}$ for $n \geq 1$, then λB is hypercyclic for any complex number λ such that $|\lambda| > 1$. This can be seen very easily using the Hypercyclicity Criterion, which is the most useful tool for proving that a given operator is hypercyclic. We recall it here in the version of Bès and Peris [2]:

Hypercyclicity Criterion. Suppose that there exist a strictly increasing sequence (n_k) of positive integers, two dense subsets V and W of X and a sequence (S_k) of maps (not necessarily linear nor continuous) $S_k: W \to W$ such that:

- (1) for every $x \in V$, $T^{n_k}x \to 0$,
- (2) for every $x \in W$, $S_k x \to 0$,
- (3) for every $x \in W$, $T^{n_k}S_kx \to x$.

Then the operator T is hypercyclic.

Despite its somewhat involved aspect, the Hypercyclicity Criterion follows directly from a simple Baire Category argument, using the fact that T is hypercyclic

The third author was partially supported by grant No. 201/06/0128 of GA CR. The main part of the paper was written during the stay of the authors in Oberwolfach, Germany, under the MFO-RiP ("Research in Pairs") programme. We would like to thank the Mathematisches Forschungsinstitut Oberwolfach for excellent working conditions.

if and only if it is topologically transitive (i.e., for every pair (U, V) of nonempty open subsets of X there exists an integer n such that $T^{-n}(U) \cap V \neq \emptyset$). The "legitimacy" of the Hypercyclicity Criterion comes from the fact [2] that $T \in \mathcal{B}(X)$ satisfies the Hypercyclicity Criterion if and only if $T \oplus T$ is hypercyclic on $X \oplus X$. Until very recently it was unknown whether every hypercyclic operator satisfied the Hypercyclicity Criterion or not: the answer is no; see [3].

Let $T \in B(X)$ satisfy the Hypercyclicity Criterion. Note that for any 0 < t < 1 the operator tT satisfies condition (1) (for the same sequence (n_k) and set V). Similarly, the operator tT for t > 1 satisfies conditions (2) and (3) (for the same set W and for the mappings $t^{-n_k}S_k$). Therefore in many concrete examples the set $\{t > 0 \mid tT$ is hypercyclic $\}$ is convex. This motivates the following question of Prăjitură [6, 5] about multiples of hypercyclic operators:

Question 1.1. Let T be a bounded operator on X. Suppose that there exist two positive numbers t_1 and t_2 , $0 < t_1 < t_2$, such that t_1T and t_2T are hypercyclic. Is it true that tT is hypercyclic for every $t \in [t_1, t_2]$?

We give a negative answer to this question and prove the following stronger result:

Theorem 1.2. Let M be a subset of $(0, +\infty)$. The following assertions are equivalent:

- (1) M is a G_{δ} subset of $(0, +\infty)$ which is bounded and bounded away from zero;
- (2) there exists an invertible operator T acting on a Hilbert space such that

$$M = \{t > 0 \mid tT \text{ is hypercyclic}\}.$$

Remark that as soon as M coincides with the set of positive t's such that tT is hypercyclic, M must be bounded away from zero, since tT is a contraction for small enough t. As a corollary to Theorem 1.2 we obtain for instance:

Corollary 1.3. There exists an operator T acting on a Hilbert space such that T and 3T are hypercyclic but 2T is not.

Note that by [4], if T is a hypercyclic operator on a complex Banach space and $\theta \in \mathbb{R}$, then $e^{i\theta}T$ is hypercyclic (with the same set of hypercyclic vectors as T). Thus the set $M = \{\lambda \in \mathbb{C} \mid \lambda T \text{ is hypercyclic}\}$ is *circularly symmetric* (if λ belongs to M, $e^{i\theta}\lambda$ belongs to M for any $e^{i\theta}$ in the unit circle). We thus obtain the following variant of Theorem 1.2:

Theorem 1.4. Let M be a subset of the complex plane \mathbb{C} . The following assertions are equivalent:

(i) there exists an invertible operator T acting on a Hilbert space such that

$$M = \{\lambda \in \mathbb{C} \mid \lambda T \text{ is hypercyclic}\};$$

(ii) M is circularly symmetric and $M \cap (0, +\infty)$ is a G_{δ} subset of $(0, +\infty)$ which is bounded and bounded away from zero.

The operators constructed in Theorem 1.2 are bilateral weighted shifts on the space $\ell_2(\mathbb{Z})$, and for these shifts the Hypercyclicity Criterion takes a particularly simple form (see [7] for a necessary and sufficient condition for a general bilateral weighted shift to be hypercyclic):

Fact 1.5. Let T be an invertible bilateral weighted shift on the space $\ell_2(\mathbb{Z})$ endowed with its canonical basis $(e_n)_{n\in\mathbb{Z}}$. Then T is hypercyclic if and only if there exists a strictly increasing sequence $(n_k)_{k\geq 0}$ of positive integers such that $||T^{n_k}e_0||$ and $||T^{-n_k}e_0||$ tend to zero as k goes to infinity.

Multiples of the shifts constructed in the proof of Theorem 1.2 are not mixing (recall that T is said to be *mixing* if for every pair (U,V) of nonempty open subsets of X there exists an integer N such that $T^{-n}(U) \cap V \neq \emptyset$ for every $n \geq N$): this is consistent with the next result, which implies that the answer to Question 1.1 is affirmative for a large class of operators.

Theorem 1.6. Let $T \in \mathcal{B}(X)$ be such that for some $0 < t_1 < t_2$, $t_1T \oplus t_2T$ is hypercyclic. Then tT is hypercyclic for every $t \in [t_1, t_2]$. This holds true in particular if either t_1T or t_2T is mixing.

2. Proofs of Theorems 1.2 and 1.6

The proof of the implication $(2) \Rightarrow (1)$ in Theorem 1.2 is quite standard: suppose that $T \in B(X)$ is invertible. Let $M = \{t > 0 \mid tT \text{ is hypercyclic}\}$. We can suppose that M is nonempty. As was previously mentioned, $||tT|| \leq 1$ for $0 < t \leq ||T||^{-1}$ and so tT is not hypercyclic in this case. Hence M is bounded away from zero. Since T is invertible, the same argument applied to T^{-1} shows that M must be bounded above. Let $(U_j)_{j\geq 1}$ be a countable basis of open subsets of X (which is separable). Clearly

$$M = \{t > 0 \mid tT \text{ is hypercyclic}\} = \bigcap_{i \ge 1} \bigcap_{j \ge 1} \bigcup_{n \ge 0} \{t > 0 \mid (tT)^n U_i \cap U_j \ne \emptyset\},$$

which is a G_{δ} set.

The first step in the proof of the reverse implication $(1) \Rightarrow (2)$ of Theorem 1.2 is the following proposition, which proves the result when M is an open set. One of its interests is that it shows the existence of *common* subsets V and W in the Hypercyclicity Criterion for *all* operators tT with t belonging to this open set.

Proposition 2.1. Let G be an open subset of an interval of the form (K^{-1}, K) for some K > 1. Then

- (i) there exists an invertible bilateral weighted shift on $\ell_2(\mathbb{Z})$ such that $||T|| \le K^3$ and $G = \{t > 0 \mid tT \text{ is hypercyclic}\};$
- (ii) write G as a (finite or countable) union

$$G = \bigcup_{\lambda \in \Lambda} (a_{\lambda}, b_{\lambda})$$

of open intervals. For each $\lambda \in \Lambda$, let A_{λ} be an infinite subset of \mathbb{N} . Then for each $\lambda \in \Lambda$ there exists an increasing sequence $(m_{\lambda,k})_{k\geq 1}$ of integers belonging to A_{λ} such that for every $t \in (a_{\lambda}, b_{\lambda})$, $\|(tT)^{m_{\lambda,k}} e_0\|$ and $\|(tT)^{-m_{\lambda,k}} e_0\|$ tend to zero as k tends to infinity (where $\{e_n \mid n \in \mathbb{Z}\}$ is the standard orthonormal basis in $\ell^2(\mathbb{Z})$).

Proof. The statement is trivial if G is empty, so suppose that G is nonempty. Order the intervals $(a_{\lambda}, b_{\lambda})$ into a sequence (a_k, b_k) in which every interval $(a_{\lambda}, b_{\lambda})$ appears infinitely many times. Then fix a function $f : \mathbb{N} \to \Lambda$ such that $(a_k, b_k) = (a_{f(k)}, b_{f(k)})$ and for each $\lambda \in \Lambda$, $f(k) = \lambda$ for infinitely many k's.

Set formally $n_0 = 1$ and choose inductively a sequence $(n_k)_{k \ge 1}$ such that $n_k \in A_{f(k)}$ and $n_k \ge 4n_{k-1}$ for each $k \ge 1$.

The operator T will be the weighted bilateral shift defined on $\ell_2(\mathbb{Z})$ by

$$Te_i = c_{i+1}e_{i+1}$$
 and $T^{-1}e_{-i} = \widetilde{c}_{i+1}e_{-i-1}$ for $i \ge 0$;

i.e. $Te_i = (1/\widetilde{c}_{-i})e_{i+1}$ for i < 0. The weights c_i and \widetilde{c}_i are defined for $i \ge 1$ in the following way:

- $c_1 = c_2 = \widetilde{c}_1 = \widetilde{c}_2 = K;$
- for $k \in \mathbb{N}$ and $2n_{k-1} < j \le n_k$,

$$c_j = \left(\frac{1}{K^{2n_{k-1}} b_k^{n_k}}\right)^{\frac{1}{n_k - 2n_{k-1}}} \quad \text{and} \quad \widetilde{c}_j = \left(\frac{a_k^{n_k}}{K^{2n_{k-1}}}\right)^{\frac{1}{n_k - 2n_{k-1}}};$$

• for $k \in \mathbb{N}$ and $n_k < j \le 2n_k$,

$$c_j = K^2 b_k$$
 and $\widetilde{c}_j = \frac{K^2}{a_k}$.

For $n \in \mathbb{N}$ write the products of the first n coefficients c_i or \widetilde{c}_i as $w_n = \prod_{i=1}^n c_i$ and $\widetilde{w}_n = \prod_{i=1}^n \widetilde{c}_i$. It is easy to show by induction that for every $k \in \mathbb{N}$,

$$w_{2n_k} = \widetilde{w}_{2n_k} = K^{2n_k}, \ w_{n_k} = b_k^{-n_k} \text{ and } \widetilde{w}_{n_k} = a_k^{n_k}.$$

Since $1/K < a_k < b_k < K$ for every k, we have for every k and every j such that $n_k < j \le 2n_k$,

$$K \le c_j \le K^3$$
 and $K \le \widetilde{c}_j \le K^3$.

Then since $n_k \ge 4n_{k-1}$, we have for $2n_{k-1} < j \le n_k$:

$$\begin{split} \frac{1}{c_j} &= \left(K^{2n_{k-1}}b_k^{n_k}\right)^{\frac{1}{n_k-2n_{k-1}}} \leq K^{\frac{2n_{k-1}+n_k}{n_k-2n_{k-1}}} \leq K^3, \\ \frac{1}{\widetilde{c}_j} &= \left(\frac{K^{2n_{k-1}}}{a_k^{n_k}}\right)^{\frac{1}{n_k-2n_{k-1}}} \leq K^{\frac{2n_{k-1}+n_k}{n_k-2n_{k-1}}} \leq K^3, \\ \widetilde{c}_i &\leq K^{\frac{n_k-2n_{k-1}}{n_k-2n_{k-1}}} \leq K \end{split}$$

and similarly, $c_j \leq K$. Hence $K \leq c_j \leq K^3$ and $K \leq \tilde{c}_j \leq K^3$ for every j, and this proves that T is bounded and invertible with $||T|| \leq K^3$ and $||T^{-1}|| \leq K^3$. Note that for $t \in (a_k, b_k)$ we have

$$\|(tT)^{n_k}e_0\| = t^{n_k}b_k^{-n_k} = (t/b_k)^{n_k} \text{ and } \|(tT)^{-n_k}e_0\| = t^{-n_k}a_k^{n_k} = (a_k/t)^{n_k},$$

where $t/b_k < 1$ and $a_k/t < 1$.

Now let $\lambda \in \Lambda$. Since the interval $(a_{\lambda}, b_{\lambda})$ appears in the sequence (a_k, b_k) infinitely many times, let $(m_{\lambda,i})_{i\geq 1}$ be the increasing sequence consisting of the integers of the set $\{n_k\}$ for which $f(k) = \lambda$. Then each $m_{\lambda,i}$ belongs to A_{λ} since $n_k \in A_{f(k)}$ for every k.

Let t belong to the interval $(a_{\lambda}, b_{\lambda})$. Then by the computation above, $||(tT)^{m_{\lambda,i}}e_0||$ and $||(tT)^{-m_{\lambda,i}}e_0||$ tend to zero as i tends to infinity, and, by Fact 1.5, tT is hypercyclic. Since this is true for every $\lambda \in \Lambda$, this shows that $G \subseteq \{t > 0 \mid tT \text{ is hypercyclic}\}$.

Conversely, suppose that t does not belong to G. In order to show that tT is not hypercyclic, it suffices to prove that for each $j \in \mathbb{N}$, $\max\{\|(tT)^j e_0\|, \|(tT)^{-j} e_0\|\} \ge 1$. Let $2n_{k-1} < j \le 2n_k$ for some $k \ge 1$. Since $t \notin G$, either $t \le a_k$ or $t \ge b_k$.

• If $n_k < j \le 2n_k$ and $t \ge b_k$, then

$$\begin{aligned} \|(tT)^{j}e_{0}\| &= t^{j}\|T^{j}e_{0}\| \ge b_{k}^{j}\|T^{n_{k}}e_{0}\| \cdot (K^{2}b_{k})^{j-n_{k}} \\ &= b_{k}^{j-n_{k}}(K^{2}b_{k})^{j-n_{k}} = (Kb_{k})^{2(j-n_{k})} \ge 1. \end{aligned}$$

• If $n_k < j \le 2n_k$ and $t \le a_k$, then

$$||(tT)^{-j}e_0|| \ge a_k^{-j}||T^{-n_k}e_0|| \cdot \left(\frac{K^2}{a_k}\right)^{j-n_k}$$

$$= a_k^{-(j-n_k)} \left(\frac{K^2}{a_k}\right)^{j-n_k} = \left(\frac{K}{a_k}\right)^{2(j-n_k)} \ge 1.$$

• If $2n_{k-1} < j \le n_k$ for some $k \ge 1$, and $t \ge b_k$, then

$$||(tT)^{j}e_{0}|| \geq b_{k}^{j}||T^{j}e_{0}|| = b_{k}^{j}||T^{n_{k}}e_{0}|| \cdot (K^{2n_{k-1}}b_{k}^{n_{k}})^{\frac{n_{k}-j}{n_{k}-2n_{k-1}}}$$

$$= b_{k}^{j-n_{k}}(K^{2n_{k-1}}b_{k}^{n_{k}})^{\frac{n_{k}-j}{n_{k}-2n_{k-1}}} = (K^{2n_{k-1}}b_{k}^{2n_{k-1}})^{\frac{n_{k}-j}{n_{k}-2n_{k-1}}} \geq 1$$

since $Kb_k \geq 1$.

• Finally if $2n_{k-1} < j \le n_k$ and $t \le a_k$, then

$$\begin{aligned} \|(tT)^{-j}e_0\| & \geq a_k^{-j}\|T^{-j}e_0\| = a_k^{-j}\|T^{-n_k}e_0\| \cdot \left(\frac{K^{2n_{k-1}}}{a_k^{n_k}}\right)^{\frac{n_k-j}{n_k-2n_{k-1}}} \\ & = a_k^{n_k-j}\left(\frac{K^{2n_{k-1}}}{a_k^{n_k}}\right)^{\frac{n_k-j}{n_k-2n_{k-1}}} = \left(\frac{K^{2n_{k-1}}}{a_k^{2n_{k-1}}}\right)^{\frac{n_k-j}{n_k-2n_{k-1}}} \geq 1 \end{aligned}$$

since $K/a_k \geq 1$ this time.

Hence $\max\{\|(tT)^j e_0\|, \|(tT)^{-j} e_0\|\} \ge 1$ for all j, and consequently, tT is not hypercyclic for $t \notin G$. This shows that $G = \{t > 0 \mid tT \text{ is hypercyclic}\}$ and finishes the proof of Proposition 2.1.

We are now ready for the proof of Theorem 1.2.

Proof of Theorem 1.2. Let K > 1 be such that $M \subseteq (1/K, K)$. Write $M = \bigcap_{j \geq 1} G_j$, where $(G_j)_{j \geq 1}$ is a decreasing sequence of nonempty open sets. Then each G_j can be decomposed as a disjoint union $G_j = \bigcup_{\lambda \in \Lambda_j} (a_\lambda, b_\lambda)$ of open intervals, where Λ_j for $j \geq 1$ are suitable finite or infinite sets. By Proposition 2.1, there exists a bilateral weighted shift T_1 such that $||T_1|| \leq K^3$ and $G_1 = \{t > 0 \mid tT_1 \text{ is hypercylic}\}$. Moreover, for each $\lambda \in \Lambda_1$ there is an increasing sequence $(m_{\lambda,i}^{(1)})_{i\geq 1}$ such that tT_1 satisfies the Hypercyclicity Criterion with respect to this sequence for each $t \in (a_\lambda, b_\lambda)$.

We then define a sequence of weighted bilateral shifts T_j , $j \geq 2$, in the following way. For each $j \geq 2$ define a (uniquely determined) function $g_j : \Lambda_j \to \Lambda_{j-1}$ such that $(a_{\lambda}, b_{\lambda}) \subseteq (a_{g_j(\lambda)}, b_{g_j(\lambda)})$ for every $\lambda \in \Lambda_j$. By Proposition 2.1 we can define inductively weighted bilateral shifts T_j such that

- $||T_i|| \leq K^3$;
- $G_j = \{t > 0 \mid tT_j \text{ is hypercyclic}\};$
- for each $\lambda \in \Lambda_j$ there is an increasing sequence $(m_{\lambda,i}^{(k)})_{i\geq 1}$ of integers such that tT_j satisfies the Hypercyclicity Criterion with respect to this sequence for each

 $t \in (a_{\lambda}, b_{\lambda}), \lambda \in \Lambda_i$. Moreover, we may assume that

$$\{m_{\lambda,i}^{(j)} \mid i \ge 1\} \subseteq \{m_{g_i(\lambda),i}^{(j-1)} \mid i \ge 1\}.$$

Consider now the direct sum $T = \bigoplus_{j=1}^{\infty} T_j$ acting on $\bigoplus_{j=1}^{\infty} \ell_2(\mathbb{Z})$. Clearly we have $||T|| \leq K^3$. Suppose that tT is hypercyclic for some t > 0. Then tT_j is hypercyclic for each $j \geq 1$ and thus $t \in G_j$ for every $j \geq 1$. Hence t belongs to M.

Conversely, let t belong to M. For each j choose the (uniquely determined) element $\lambda^{(j)}$ of Λ_j such that $t \in (a_{\lambda^{(j)}}, b_{\lambda^{(j)}})$. Consider the sequence $(m_k)_{k \geq 1} = (m_{\lambda^{(k)},k}^{(k)})_{k \geq 1}$. Then it is easy to check that tT satisfies the Hypercyclicity Criterion with respect to the sequence $(m_k)_{k \geq 1}$, and Theorem 1.2 is proved.

The proof of Theorem 1.6 is a straightforward application of the Hypercyclicity Criterion:

Proof of Theorem 1.6. Let $t \in (t_1, t_2)$. In order to show that tT satisfies the Hypercyclicity Criterion, it suffices to prove that for all nonempty open subsets U, V of X and for any open neighborhood W of 0 there exists an $n \in \mathbb{N}$ such that $T^n(W) \cap V$ and $T^n(U) \cap W$ are nonempty. Let $\varepsilon > 0$ be such that the open ball of radius ε is contained in W. Since $t_1T \oplus t_2T$ is hypercyclic, there exists a vector $x \oplus y$ with $||x|| < \varepsilon$ and $y \in U$ which is hypercyclic for $t_1T \oplus t_2T$. Thus there exists an $n \in \mathbb{N}$ such that $(t_1T)^n x \in V$ and $||(t_2T)^n y|| < \varepsilon$. Then $||t_1^n t^{-n} x|| \leq ||x|| < \varepsilon$, so $t_1^n t^{-n} x \in W$, and $(tT)^n t_1^n t^{-n} x = (t_1T)^n x \in V$. Hence $(tT)^n(W) \cap V \neq \emptyset$. Furthermore, $||(tT)^n y|| \leq ||(t_2T)^n y|| < \varepsilon$, and so $(tT)^n(U) \cap W \neq \emptyset$. Hence tT is hypercyclic.

In view of Theorem 1.6, one may wonder whether the condition $t_1T \oplus t_2T$ hypercyclic is necessary for tT to be hypercyclic whenever t belongs to $[t_1, t_2]$. This is not the case, as shown by the following example:

Example 2.2. There exists a bilateral weighted shift T on $\ell_2(\mathbb{Z})$ such that tT is hypercyclic for every $t \in (1,4)$ but $2T \oplus 3T$ is not hypercyclic.

Proof. We define T using the notation of the proof of Proposition 2.1 with $M=(a_1,b_1)\cup(a_2,b_2)$, where $\Lambda=\{1,2\}$, $(a_1,b_1)=(1,3)$ and $(a_2,b_2)=(2,4)$. Then we define the function f as f(k)=1 if k is odd and f(k)=2 if k is even. Let K=5 and construct a sequence (n_k) and the operator T as in Proposition 2.1. The proof of Proposition 2.1 shows that tT is hypercyclic if and only if $t\in(1,3)\cup(2,4)=(1,4)$. Furthermore, it is easy to check that $2T\oplus 3T$ is not hypercyclic. Indeed if k is odd, then:

• If $2n_{k-1} < j \le n_k$,

$$w_j = 5^{2n_{k-1}} \left(\frac{1}{5^{2n_{k-1}} 3^{n_k}} \right)^{\frac{j-2n_{k-1}}{n_k - 2n_{k-1}}}.$$

Hence $||(3T)^{j}e_{0}|| = 3^{j}w_{j} = (15)^{2n_{k-1}} \left(\frac{1}{15^{2n_{k-1}}}\right)^{\frac{j-2n_{k-1}}{n_{k}-2n_{k-1}}} = 15^{\frac{2n_{k-1}(n_{k}-j)}{n_{k}-2n_{k-1}}} \ge 1.$

• If $n_k < j \le 2n_k$, $||(3T)^j e_0|| = 3^j w_j = 15^{2(j-n_k)} \ge 1$. If k is even, then • If $2n_{k-1} < j \le n_k$,

$$||(2T)^{-j}e_0|| = 2^{-j}\widetilde{w}_j = (5/2)^{2n_{k-1}} \left(\frac{1}{(2/5)^{2n_{k-1}}}\right)^{\frac{j-2n_{k-1}}{n_k-2n_{k-1}}} \ge 1.$$

• If $n_k < j \le 2n_k$, $||(2T)^{-j}e_0|| = 2^{-j}\widetilde{w}_j = (5/2)^{2(j-n_k)} \ge 1$.

Hence there is no sequence (m_j) such that both $||(2T)^{m_j}e_0 \oplus (3T)^{m_j}e_0||$ and $||(2T)^{-m_j}e_0 \oplus (3T)^{-m_j}e_0||$ tend to zero as j tends to infinity and $2T \oplus 3T$ is not hypercyclic.
