LOG CANONICAL MODELS FOR THE MODULI SPACE OF STABLE POINTED RATIONAL CURVES

HAN-BOM MOON

(Communicated by Lev Borisov)

ABSTRACT. We run Mori’s program for the moduli space of stable pointed rational curves with divisor $K + \sum a_i \psi_i$. We prove that the birational model for the pair is either the Hassett space of weighted pointed stable rational curves for the same weights or the GIT quotient of the product of projective lines with the linearization given by the same weights.

1. INTRODUCTION

The Knudsen-Mumford space $\overline{M}_{0,n}$, or the moduli space of stable pointed rational curves, is one of the most concrete and well-studied moduli spaces in algebraic geometry. For example, it is well-known that $\overline{M}_{0,n}$ is a smooth projective fine moduli space ([Kee92, Knu83]). Also the cohomology ring, the Chow ring, and the Picard group are known ([Kee92]). There are several concrete constructions by using explicit methods such as smooth blow-ups ([Kap93, Kee92]) or by geometric invariant theory (GIT) as quotients by $SL(2)$ ([HK00, KM11]). Furthermore, there are various different compactifications of the space of smooth pointed rational curves such as Hassett’s moduli spaces of weighted stable pointed rational curves $\overline{M}_{0,\mathcal{A}}$ ([Has03]), the GIT quotients of the product of the projective lines ([Kap93]) with various effective linearizations, and the moduli spaces of pointed conics ([GS10]). All of them are birational models of $\overline{M}_{0,n}$.

In spite of these numerous achievements, the birational geometric aspects of $\overline{M}_{0,n}$ are not fully understood yet. For instance, the Mori cone $\overline{NE}_1(\overline{M}_{0,n})$ (dually, the nef cone $\text{Nef}(\overline{M}_{0,n})$) is unknown. There is only a conjectural description of this cone that is proved for $n \leq 7$ ([KMc96]).

Conjecture 1.1 (F-conjecture). *Any effective curve in $\overline{M}_{0,n}$ is numerically equivalent to a nonnegative linear combination of F -curves. In other words, every extremal ray of $\overline{NE}_1(\overline{M}_{0,n})$ is generated by F -curve classes.*

Recently, there has been a tremendous amount of interest in the birational geometry of $\overline{M}_{0,n}$ ([AS08, Fed10, FS08, GG11, GS10, GKM02, Has03, HK00, Kap93, Sim07]) and more generally of $\overline{M}_{g,n}$. In particular, one can run Mori’s program (or the minimal model program) for $\overline{M}_{0,n}$ with a big $\mathbb{Q}$ -divisor D of $\overline{M}_{0,n}$ by finding a

birational model

$$(1) \quad \overline{M}_{0,n}(D) := \text{Proj} \left(\bigoplus_{l \geq 0} H^0(\overline{M}_{0,n}, \mathcal{O}(lD)) \right),$$

where the sum is taken over l sufficiently divisible.

The most prominent two results in this direction are the following. Set $m = \lfloor \frac{n}{2} \rfloor$. Let ϵ_k be a rational number in the range $\frac{1}{m+1-k} < \epsilon_k \leq \frac{1}{m-k}$ for $k = 1, 2, \dots, m-2$. For $\epsilon > 0$, let $n \cdot \epsilon = (\epsilon, \dots, \epsilon)$ be a *symmetric weight datum*.

Theorem 1.2 (Simpson [AS08, FS08, KM11, Sim07]). *Let β be a rational number satisfying $\frac{2}{n-1} < \beta \leq 1$ and let $D = \overline{M}_{0,n} - M_{0,n}$ denote the total boundary divisor. Then the log canonical model*

$$(2) \quad \overline{M}_{0,n}(K_{\overline{M}_{0,n}} + \beta D) = \text{Proj} \left(\bigoplus_{l \geq 0} H^0(\overline{M}_{0,n}, \mathcal{O}(l(K_{\overline{M}_{0,n}} + \beta D))) \right)$$

satisfies the following:

- (1) *If $\frac{2}{m-k+2} < \beta \leq \frac{2}{m-k+1}$ for $1 \leq k \leq m-2$, then $\overline{M}_{0,n}(K_{\overline{M}_{0,n}} + \beta D) \cong \overline{M}_{0,n \cdot \epsilon_k}$.*
- (2) *If $\frac{2}{n-1} < \beta \leq \frac{2}{m+1}$, then $\overline{M}_{0,n}(K_{\overline{M}_{0,n}} + \beta D) \cong (\mathbb{P}^1)^n // SL(2)$, where the quotient is taken with respect to the symmetric linearization $\mathcal{O}(1, \dots, 1)$.*

The other result concerning both *nonsymmetric* weights and higher genera is the following theorem of Fedorchuk. It is an answer to a question of Hassett ([Has03, Problem 7.1]).

Theorem 1.3 ([Fed10]). *For every genus g and weight datum $\mathcal{A}$, there exists a log canonical divisor $D_{g,\mathcal{A}}$ on $\overline{M}_{g,n}$ such that the log canonical model $\overline{M}_{g,n}(K_{\overline{M}_{g,n}} + D_{g,\mathcal{A}})$ is isomorphic to $\overline{M}_{g,\mathcal{A}}$.*

In this paper, we prove a *universal* formula generalizing Theorem 1.2 to non-symmetric weights $\mathcal{A} = (a_1, \dots, a_n)$.

Theorem 1.4. *Let $\mathcal{A} = (a_1, \dots, a_n)$ be a weight datum. Then:*

- (1) *If $\sum_{i=1}^n a_i > 2$, then the log canonical model $\overline{M}_{0,n}(K_{\overline{M}_{0,n}} + \sum_{i=1}^n a_i \psi_i)$ is isomorphic to $\overline{M}_{0,\mathcal{A}}$.*
- (2) *Assume that $n \geq 5$. If $\sum_{i=1}^n a_i = 2$, then $\overline{M}_{0,n}(K_{\overline{M}_{0,n}} + \sum_{i=1}^n a_i \psi_i)$ is isomorphic to $(\mathbb{P}^1)^n //_{L} SL(2)$, where L is the linearization $\mathcal{O}(a_1, \dots, a_n)$.*

In Theorem 1.4, item (2), if $n = 4$ it is easy to check that $K_{\overline{M}_{0,4}} + \sum_{i=1}^4 a_i \psi_i$ is numerically trivial.

Here is an outline of the proof of Theorem 1.4, item (1). Let $\Delta_{\mathcal{A}} = K_{\overline{M}_{0,n}} + \sum_{i=1}^n a_i \psi_i$. Let $\varphi_{\mathcal{A}} : \overline{M}_{0,n} \rightarrow \overline{M}_{0,\mathcal{A}}$ be the reduction morphism (see Section 2.1). By computing the push-forwards and pull-backs of divisors (see Section 2.2), we prove that $\Delta_{\mathcal{A}} - \varphi_{\mathcal{A}}^* \varphi_{\mathcal{A}*}(\Delta_{\mathcal{A}})$ is an effective divisor supported on the exceptional locus of $\varphi_{\mathcal{A}}$. Thus

$$H^0(\overline{M}_{0,n}, \mathcal{O}(l\Delta_{\mathcal{A}})) \cong H^0(\overline{M}_{0,\mathcal{A}}, \mathcal{O}(l\varphi_{\mathcal{A}*}(\Delta_{\mathcal{A}})))$$

for any positive integer l by [Deb01, Lemma 7.11]. Hence if we prove that $\varphi_{\mathcal{A}*}(\Delta_{\mathcal{A}})$ is ample on $\overline{M}_{0,\mathcal{A}}$, then we have

$$\begin{aligned}\overline{M}_{0,n}(\Delta_{\mathcal{A}}) &= \operatorname{Proj} \left(\bigoplus_{l \geq 0} H^0(\overline{M}_{0,n}, \mathcal{O}(l\Delta_{\mathcal{A}})) \right) \\ &\cong \operatorname{Proj} \left(\bigoplus_{l \geq 0} H^0(\overline{M}_{0,\mathcal{A}}, \mathcal{O}(l\varphi_{\mathcal{A}*}(\Delta_{\mathcal{A}}))) \right) \cong \overline{M}_{0,\mathcal{A}}.\end{aligned}$$

For proving the ampleness of $\varphi_{\mathcal{A}*}(\Delta_{\mathcal{A}})$, we follow the strategy of Fedorchuk in [Fed10]. First, we can express $\varphi_{\mathcal{A}*}(\Delta_{\mathcal{A}})$ in terms of tautological divisors on $\overline{M}_{0,\mathcal{A}}$. Then by using a positivity result of Fedorchuk (Proposition 3.3) and induction on the dimension, we prove that $\varphi_{\mathcal{A}*}(\Delta_{\mathcal{A}})$ intersects all effective curves nonnegatively, so it is nef. Moreover, we prove that small perturbations of $\varphi_{\mathcal{A}*}(\Delta_{\mathcal{A}})$ by boundary divisors are again nef. Since the Neron-Severi vector space $N^1(\overline{M}_{0,\mathcal{A}})$ is generated by the boundary divisor classes, this implies that $\varphi_{\mathcal{A}*}(\Delta_{\mathcal{A}})$ lies in the interior of $\operatorname{Nef}(\overline{M}_{0,\mathcal{A}})$, so it is ample by Kleiman's criterion.

This paper is organized as follows. In section 2, we give some well-known facts about $\overline{M}_{0,\mathcal{A}}$ and its divisor classes. Essentially there is no new result in this section. In section 3, we give a proof of Theorem 1.4.

2. SOME PRELIMINARIES

2.1. Moduli space of weighted pointed rational stable curves. A *weight datum* $\mathcal{A} = (a_1, \dots, a_n)$ is a sequence of rational numbers such that $0 < a_i \leq 1$. A family of nodal curves of genus g with n marked points over a base scheme B consists of a flat proper morphism $\pi : C \rightarrow B$ whose geometric fibers are nodal connected curves with arithmetic genus g , and n sections $s_1, \dots, s_n$ of π .

Definition 2.1 ([Has03, Section 2]). Let $\mathcal{A}$ be a weight datum satisfying $2g - 2 + \sum_{i=1}^n a_i > 0$. A family of nodal curves of genus g with n marked points $\pi : (C, s_1, \dots, s_n) \rightarrow B$ is $\mathcal{A}$ -stable if

- (1) the sections $s_1, \dots, s_n$ lie in the smooth locus of π ;
- (2) for any subset $\{s_{i_1}, \dots, s_{i_r}\}$ of nonempty intersection, $a_{i_1} + \dots + a_{i_r} \leq 1$;
- (3) $\omega_{\pi} + \sum_{i=1}^n a_i s_i$ is π -ample.

For any weight datum $\mathcal{A}$ such that $2g - 2 + \sum_{i=1}^n a_i > 0$, there exists a connected irreducible smooth Deligne-Mumford stack $\overline{\mathcal{M}}_{g,\mathcal{A}}$ such that its coarse moduli space $\overline{M}_{g,\mathcal{A}}$ is projective ([Has03, Theorem 2.1]). Note that when $a_1 = \dots = a_n = 1$, $\overline{\mathcal{M}}_{g,\mathcal{A}} = \overline{\mathcal{M}}_{g,n}$. If $g = 0$, then $\overline{\mathcal{M}}_{0,\mathcal{A}}$ is a fine moduli space, so $\overline{\mathcal{M}}_{0,\mathcal{A}} = \overline{M}_{0,\mathcal{A}}$. From now on, we will focus on the $g = 0$ case only.

Let $\mathcal{A} = (a_1, \dots, a_n)$, $\mathcal{B} = (b_1, \dots, b_n)$ be two weight data and suppose that $a_i \geq b_i$ for all $i = 1, 2, \dots, n$. Then there exists a birational *reduction morphism* ([Has03, Theorem 4.1])

$$\varphi_{\mathcal{A},\mathcal{B}} : \overline{M}_{0,\mathcal{A}} \rightarrow \overline{M}_{0,\mathcal{B}}.$$

For $(C, s_1, \dots, s_n) \in \overline{M}_{0,\mathcal{A}}$, $\varphi_{\mathcal{A},\mathcal{B}}(C, s_1, \dots, s_n)$ is obtained by collapsing components on which $\omega_C + \sum b_i s_i$ fails to be ample. Every reduction morphism is a

composition of smooth blow-downs ([KM11, Mo11]). In this article, we use reduction morphisms from $\overline{M}_{0,n}$ only. So we use the more concise notation

$$\varphi_{\mathcal{A}} := \varphi_{(1, \dots, 1), \mathcal{A}} : \overline{M}_{0,n} \rightarrow \overline{M}_{0,\mathcal{A}}.$$

2.2. Tautological divisors on $\overline{M}_{0,\mathcal{A}}$. In this section, we recall some information about several functorial divisors on $\overline{M}_{0,\mathcal{A}}$. The results in this section are drawn from several sources, including [AC96, AC99, Fed10, FS08, HM98, Has03].

Let $[n] = \{1, \dots, n\}$. For $I \subset [n]$ such that $2 \leq |I| \leq n-2$, let $D_I \subset \overline{M}_{0,n}$ be the closure of the locus of curves C with two irreducible components C_I, C_{I^c} such that the i -th marked point is lying on C_I if and only if $i \in I$. So $D_I = D_{I^c}$. These divisors are called *boundary divisors*. By [Kee92], boundary divisors generate the Picard group $\text{Pic}(\overline{M}_{0,n})$ and the Neron-Severi vector space $N^1(\overline{M}_{0,n})$.

Definition 2.2. Let $\mathcal{A} = (a_1, \dots, a_n)$ be a weight datum such that $\sum_{i=1}^n a_i > 2$. For $I \subset [n]$, let $w_I := \sum_{i \in I} a_i$. There are two kinds of boundary divisor classes in $\overline{M}_{0,\mathcal{A}}$ for a general weight datum $\mathcal{A}$.

- (1) *Boundary of nodal curves:* Suppose that $w_{I^c} \geq w_I > 1$. Let D_I be the divisor of $\overline{M}_{0,\mathcal{A}}$ corresponding to the closure of the locus of curves with two irreducible components C_I, C_{I^c} and $s_i \in C_I$ if and only if $i \in I$. Let D_{nod} be the sum of all boundaries of nodal curves.
- (2) *Boundary of curves with coincident sections:* Suppose that $I = \{i, j\}$ and $w_I \leq 1$. Since $w = w_{[n]} > 2$, this implies $w_{I^c} > w_I$. Let D_I be the locus of $s_i = s_j$. Let D_{sec} be the sum of all boundaries of curves with coincident sections.

Since the reduction morphism $\varphi_{\mathcal{A}}$ is a composition of smooth blow-ups, one can easily derive the following push-forward and pull-back formulas for divisor classes.

Lemma 2.3. Let $\varphi_{\mathcal{A}} : \overline{M}_{0,n} \rightarrow \overline{M}_{0,\mathcal{A}}$ be the reduction morphism. For $I \subset [n]$, let $w_I = \sum_{i \in I} a_i$. Assume $w_I \leq w_{I^c}$ for every D_I . Then:

$$\begin{aligned} (1) \quad \varphi_{\mathcal{A}*}(D_I) &= \begin{cases} 0, & |I| \geq 3 \text{ and } w_I \leq 1, \\ D_I, & \text{otherwise.} \end{cases} \\ (2) \quad \varphi_{\mathcal{A}}^*(D_I) &= \begin{cases} D_I + \sum_{J \supset I, w_J \leq 1} D_J, & D_I \text{ is a boundary of curves} \\ & \text{with coincident sections,} \\ D_I, & \text{otherwise.} \end{cases} \end{aligned}$$

Let $\pi : U \rightarrow \overline{M}_{0,\mathcal{A}}$ be the universal curve and $\sigma_i : \overline{M}_{0,\mathcal{A}} \rightarrow U$ for $i = 1, \dots, n$ be the universal sections. Let $\omega = \omega_{U/\overline{M}_{0,\mathcal{A}}}$ be the relative dualizing bundle. We define tautological divisors on $\overline{M}_{0,\mathcal{A}}$ as follows:

- (1) The *kappa class* is $\kappa = \pi_*(c_1^2(\omega))$. This definition is different from κ_1 in [AC99].
- (2) For $1 \leq i \leq n$, let $\mathbb{L}_i$ be the line bundle on $\overline{M}_{0,\mathcal{A}}$ whose fiber over $(C, s_1, s_2, \dots, s_n)$ is $\Omega_C|_{s_i}$, a cotangent space at s_i in C . The *i*-th *psi class* is $\psi_i = c_1(\mathbb{L}_i)$. In terms of intersection theory, $\psi_i = \pi_*(\omega \cdot \sigma_i) = \pi_*(-\sigma_i^2)$. The *total psi class* is $\psi = \sum_{i=1}^n \psi_i$.
- (3) The boundary of curves with coincident sections $D_{\{i,j\}}$ is equal to $\pi_*(\sigma_i \cdot \sigma_j)$.

We focus on the genus zero case only, so the *lambda class* $\lambda = c_1(\pi_*(\omega))$ is zero.

Next, consider the push-forwards and pull-backs of several divisors.

Lemma 2.4. *Let $\varphi_{\mathcal{A}} : \overline{M}_{0,n} \rightarrow \overline{M}_{0,\mathcal{A}}$ be the reduction morphism. Then:*

- (1) $\varphi_{\mathcal{A}*}(K_{\overline{M}_{0,n}}) = K_{\overline{M}_{0,\mathcal{A}}}.$
- (2) $\varphi_{\mathcal{A}*}(\psi_i) = \psi_i + \sum_{\substack{j \neq i \\ a_i + a_j \leq 1}} D_{\{i,j\}}.$
- (3) $\varphi_{\mathcal{A}}^*(\psi_i) = \psi_i - \sum_{\substack{i \in I \\ w_I \leq 1}} D_I.$

Proof. Since the discrepancy is supported on the exceptional locus, item (1) follows immediately. Items (2) and (3) are more careful observations of the proof of [FS08, Lemma 2.4] and [FS08, Lemma 2.8] respectively. Item (3) is also a corollary of cumbersome computation using Lemmas 2.3 and 2.9. $\square$

For $I = \{i_1, \dots, i_r\} \subset [n]$, let D_I be a boundary of nodal curves. Set $I^c = \{j_1, \dots, j_s\}$. Then D_I is isomorphic to $\overline{M}_{0,\mathcal{A}_I} \times \overline{M}_{0,\mathcal{A}_{I^c}}$, where $\mathcal{A}_I = (a_{i_1}, \dots, a_{i_r}, 1)$ and $\mathcal{A}_{I^c} = (a_{j_1}, \dots, a_{j_s}, 1)$. Let $\eta_I : \overline{M}_{0,\mathcal{A}_I} \times \overline{M}_{0,\mathcal{A}_{I^c}} \rightarrow D_I \hookrightarrow \overline{M}_{0,\mathcal{A}}$ be the inclusion morphism. Define π_i for $i = 1, 2$ as the projection from $\overline{M}_{0,\mathcal{A}_I} \times \overline{M}_{0,\mathcal{A}_{I^c}}$ to the i -th component.

Lemma 2.5. *Let $\eta_I : \overline{M}_{0,\mathcal{A}_I} \times \overline{M}_{0,\mathcal{A}_{I^c}} \rightarrow D_I \hookrightarrow \overline{M}_{0,\mathcal{A}}$ be the inclusion morphism. Let p (resp. q) denote the last index of $\mathcal{A}_I$ (resp. $\mathcal{A}_{I^c}$) with weight one. Then:*

- (1) $\eta_I^*(\kappa) = \pi_1^*(\kappa + \psi_p) + \pi_2^*(\kappa + \psi_q).$
- (2) $\eta_I^*(\psi_i) = \begin{cases} \pi_1^*(\psi_i), & i \in I, \\ \pi_2^*(\psi_i), & i \in I^c. \end{cases}$
- (3) *For $J \subset [n]$, suppose that D_J is a boundary of nodal curves:*

$$\eta_I^*(D_J) = \begin{cases} \pi_1^*(D_J), & J \subsetneq I, \\ \pi_2^*(D_J), & J \subsetneq I^c, \\ \pi_1^*(-\psi_p) + \pi_2^*(-\psi_q), & J = I, \\ 0, & \text{otherwise.} \end{cases}$$

- (4) *Suppose that $a_i + a_j \leq 1$:*

$$\eta_I^*(D_{\{i,j\}}) = \begin{cases} \pi_1^*(D_{\{i,j\}}), & i, j \in I, \\ \pi_2^*(D_{\{i,j\}}), & i, j \in I^c, \\ 0, & \text{otherwise.} \end{cases}$$

Proof. The proofs of these items are essentially identical to the case of $\overline{M}_{0,n}$. Item (1) is in [AC96, Section 1]. Items (2) and (4) are clear. The only nonobvious part of item (3) is due to [HM98, Proposition 3.31]. $\square$

Let $J \subset [n]$ be a subset of $[n]$ such that $\sum_{j \in J} a_j \leq 1$. Let $\mathcal{A}'$ be the new weight datum obtained by replacing weights indexed by J by one weight $\sum_{j \in J} a_j$. Then the locus of $\sigma_i = \sigma_j$ for all $i, j \in J$ is isomorphic to $\overline{M}_{0,\mathcal{A}'}$ because we can replace sections $\{\sigma_j\}_{j \in J}$ by one section with weight $\sum_{j \in J} a_j$. Let $\chi_J : \overline{M}_{0,\mathcal{A}'} \hookrightarrow \overline{M}_{0,\mathcal{A}}$ be the replacement morphism.

Lemma 2.6. *Let $\chi_J : \overline{M}_{0,\mathcal{A}'} \rightarrow \overline{M}_{0,\mathcal{A}}$ be the replacement morphism. Let p denote the unique index of $\mathcal{A}'$ replacing indices in J . Then:*

- (1) $\chi_J^*(\psi_i) = \begin{cases} \psi_i, & i \notin J, \\ \psi_p, & i \in J. \end{cases}$

$$(2) \quad \chi_J^*(D_{\text{nod}}) = D_{\text{nod}}.$$

(3) Suppose that $D_{\{i,j\}}$ is a boundary of curves with coincident sections:

$$\chi_J^*(D_{\{i,j\}}) = \begin{cases} D_{\{i,j\}}, & i, j \notin J, \\ D_{\{i,p\}}, & i \notin J, j \in J, \\ -\psi_p, & i, j \in J. \end{cases}$$

Proof. Essentially this is a restatement of [FS08, Lemma 2.9]. $\square$

Finally, let us recall the canonical divisor of $\overline{M}_{0,\mathcal{A}}$. The following formula is a consequence of Hassett's computation of the canonical divisor and the weighted version of Mumford's relation. By [Has03, Section 3.3.1],

$$(3) \quad K_{\overline{M}_{0,\mathcal{A}}} = \frac{13}{12}\kappa - \frac{11}{12}D_{\text{nod}} + \sum_{i=1}^n \psi_i.$$

In the proof of Mumford's relation $\kappa = 12\lambda - D_{\text{nod}}$ ([Mum77]) for $\overline{M}_g$, Mumford used only the facts 1) the parametrized curves have at worst nodal singularities only, 2) the singular locus of the morphism from the universal curve to the moduli space has codimension two. Thus the same proof holds for $\overline{M}_{0,\mathcal{A}}$, too. Note that $\lambda = 0$ for the genus zero case.

Lemma 2.7.

$$(4) \quad K_{\overline{M}_{0,\mathcal{A}}} = -2D_{\text{nod}} + \sum_{i=1}^n \psi_i = 2\kappa + \sum_{i=1}^n \psi_i.$$

2.3. Numerical results for $\overline{M}_{0,n}$. It is well known that the Neron-Severi vector space $N^1(\overline{M}_{0,n})$ of numerical divisor classes is generated by boundary divisors ([Kee92]). Many natural divisors on $\overline{M}_{0,n}$ are already expressed as linear combinations of boundary divisors. For $j = 2, 3, \dots, n-2$, let $D_j = \sum_{|I|=j} D_I$.

Lemma 2.8 ([Pan97, Proposition 2]).

$$K_{\overline{M}_{0,n}} \equiv \sum_{j=2}^{\lfloor n/2 \rfloor} \left(\frac{j(n-j)}{n-1} - 2 \right) D_j.$$

To describe psi-classes as combinations of boundary divisors, we recall a notation in [FG03, Section 2]. For $I \subset [n]$, let

$$D_j^{I,i} := \sum_{\substack{A \subset I, |A|=i \\ B \subset I^c, |B|=j}} D_{A \cup B}.$$

Lemma 2.9. On $\overline{M}_{0,n}$,

(1)

$$\psi_i \equiv \sum_{j=1}^{n-3} \frac{(n-1-j)(n-2-j)}{(n-1)(n-2)} D_j^{\{i\},1},$$

(2)

$$\psi \equiv \sum_{j=2}^{\lfloor n/2 \rfloor} \left(\frac{j(n-j)}{n-1} \right) D_j \equiv K_{\overline{M}_{0,n}} + 2D.$$

Proof. The first item is [FG03, Lemma 1]. The second item follows from a direct computation using (1) and Lemma 2.8. $\square$

Let $I_1 \sqcup I_2 \sqcup I_3 \sqcup I_4 = [n]$ be a partition. Let F_{I_1, I_2, I_3, I_4} be an F-curve class corresponding to the partition ([KMc96, Section 4]). The intersection numbers of F-curves and boundary divisors are well-known.

Lemma 2.10 ([KMc96, Lemma 4.3]). *Let $F = F_{I_1, I_2, I_3, I_4}$ be an F-curve, and let D_I be a boundary divisor. Then:*

- (1) $D_I \cdot F = -1$ if I or I^c is one of I_i .
- (2) $D_I \cdot F = 1$ if I is $I_i \sqcup I_j$ for some distinct i, j .
- (3) Otherwise, $D_I \cdot F = 0$.

From these results, we can calculate all the intersection numbers we want.

3. PROOF OF THE MAIN THEOREM

In this section, we prove our main theorem. Throughout this section, we will assume $n \geq 4$. If $n = 3$, then $\overline{M}_{0,3}$ is a point, so there is nothing to prove.

Theorem 3.1. *Let $\mathcal{A} = (a_1, \dots, a_n)$ be a weight datum such that $\sum_{i=1}^n a_i > 2$. Then the log canonical model $\overline{M}_{0,n}(K_{\overline{M}_{0,n}} + \sum_{i=1}^n a_i \psi_i)$ is isomorphic to $\overline{M}_{0,\mathcal{A}}$.*

Proof. Fix a weight datum $\mathcal{A} = (a_1, \dots, a_n)$. Let $\Delta_{\mathcal{A}} = K_{\overline{M}_{0,n}} + \sum_{i=1}^n a_i \psi_i$. Set $T = \{I \subset [n] \mid w_I = \sum_{i \in I} a_i \leq 1, 2 \leq |I| \leq n-2\}$. By Lemmas 2.4 and 2.7, it is straightforward to check that

$$\begin{aligned} \varphi_{\mathcal{A}*}(\Delta_{\mathcal{A}}) &= K_{\overline{M}_{0,\mathcal{A}}} + \sum_{i=1}^n a_i \psi_i + \sum_{\substack{i < j \\ a_i + a_j \leq 1}} (a_i + a_j) D_{\{i,j\}} \\ (5) \quad &= -2D_{\text{nod}} + \sum_{i=1}^n (1 + a_i) \psi_i + \sum_{\substack{i < j \\ a_i + a_j \leq 1}} (a_i + a_j) D_{\{i,j\}}. \end{aligned}$$

By Lemmas 2.3 and 2.4,

$$\begin{aligned} \varphi_{\mathcal{A}}^* \varphi_{\mathcal{A}*}(\Delta_{\mathcal{A}}) &= -2D_{\text{nod}} + 2 \sum_{I \in T} D_I + \sum_{i=1}^n (1 + a_i) \psi_i - \sum_{I \in T} (|I| + w_I) D_I \\ (6) \quad &+ \sum_{\substack{i < j \\ a_i + a_j \leq 1}} (a_i + a_j) D_{\{i,j\}} + \sum_{\substack{I \in T \\ |I| \geq 3}} (|I| - 1) w_I D_I \\ &= -2D_{\text{nod}} + \sum_{i=1}^n (1 + a_i) \psi_i + \sum_{I \in T} (|I| - 2)(w_I - 1) D_I. \end{aligned}$$

So

$$(7) \quad \Delta_{\mathcal{A}} - \varphi_{\mathcal{A}}^* \varphi_{\mathcal{A}*}(\Delta_{\mathcal{A}}) = \sum_{I \in T} (|I| - 2)(1 - w_I) D_I.$$

Note that for every $I \in T$, $|I| \geq 2$ and $w_I \leq 1$ by the definition of T . So the difference $\Delta_{\mathcal{A}} - \varphi_{\mathcal{A}}^* \varphi_{\mathcal{A}*}(\Delta_{\mathcal{A}})$ is supported on the exceptional locus of $\varphi_{\mathcal{A}}$ and is effective. This implies that

$$H^0(\overline{M}_{0,n}, \Delta_{\mathcal{A}}) \cong H^0(\overline{M}_{0,n}, \varphi_{\mathcal{A}}^* \varphi_{\mathcal{A}*}(\Delta_{\mathcal{A}})) \cong H^0(\overline{M}_{0,\mathcal{A}}, \varphi_{\mathcal{A}*}(\Delta_{\mathcal{A}}))$$

by [Deb01, Lemma 7.11]. The same statement holds for a positive multiple of $\Delta_{\mathcal{A}}$, too. Therefore from the definition of the log canonical model, we obtain

$$(8) \quad \begin{aligned} \overline{M}_{0,n}(K_{\overline{M}_{0,n}} + \sum_{i=1}^n a_i \psi_i) &= \text{Proj} \left(\bigoplus_{l \geq 0} H^0(\overline{M}_{0,n}, \mathcal{O}(l\Delta_{\mathcal{A}})) \right) \\ &= \text{Proj} \left(\bigoplus_{l \geq 0} H^0(\overline{M}_{0,\mathcal{A}}, \mathcal{O}(l\varphi_{\mathcal{A}*}(\Delta_{\mathcal{A}}))) \right). \end{aligned}$$

If we prove that $\varphi_{\mathcal{A}*}(\Delta_{\mathcal{A}})$ is ample, then the last birational model is exactly $\overline{M}_{0,\mathcal{A}}$. So to prove the main theorem, it suffices to show that $\varphi_{\mathcal{A}*}(\Delta_{\mathcal{A}})$ is ample on $\overline{M}_{0,\mathcal{A}}$. This is done in Propositions 3.2 and 3.5. $\square$

Proposition 3.2. *Let $\mathcal{A} = (a_1, \dots, a_n)$ be a weight datum and let $\Delta_{\mathcal{A}} = K_{\overline{M}_{0,n}} + \sum_{i=1}^n a_i \psi_i$. Then $\varphi_{\mathcal{A}*}(\Delta_{\mathcal{A}})$ is a nef divisor on $\overline{M}_{0,\mathcal{A}}$.*

The key ingredient is the following positivity result of Fedorchuk ([Fed10]). Fedorchuk gives an elementary and beautiful intersection theoretical proof of this result. As Fedorchuk mentioned in [Fed10], it can be proved by using the semipositivity method of Kollár in [Kol90, Corollary 4.6, Proposition 4.7].

Proposition 3.3 ([Fed10, Proposition 2.1]). *Let $\pi : S \rightarrow B$ be a generically smooth family of nodal curves of arithmetic genus g , with n sections $\sigma_1, \dots, \sigma_n$ over a smooth complete curve B . For a weight datum $\mathcal{A} = (a_1, \dots, a_n)$, suppose that*

$$L := \omega_{\pi} + \sum_{i=1}^n a_i \sigma_i$$

is π -nef. Suppose further that $\sigma_{i_1}, \dots, \sigma_{i_k}$ can coincide only if $\sum_{j=1}^k a_{i_j} \leq 1$. Then L is nef on S .

If $\pi : S \rightarrow B$ is a generically smooth family of $\mathcal{A}$ -stable curves or, more generally, $\mathcal{A}$ -semistable curves (allowing irreducible rational components with 2 nodes and no marked points), then the hypotheses of Proposition 3.3 are satisfied by the definition of $\mathcal{A}$ -stability.

We need an effectivity result first.

Lemma 3.4. *Let $\pi : S \rightarrow B$ be a family of $\mathcal{A}$ -semi-stable rational curves with n sections $\sigma_1, \dots, \sigma_n$ over a smooth complete curve B . Then $2\omega_{\pi} + \sum_{i=1}^n \sigma_i$ is effective.*

Proof. We will use induction on n . For the $n = 4$ case, the result is a direct computation.

By [HM98, Section 3.C], S has at worst A_k singularities only. An A_k singularity is Du Val, so if $\rho : \tilde{S} \rightarrow S$ is a minimal resolution, then $\omega_{\pi \circ \rho} = \rho^*(\omega_{\pi})$ and $\rho_*(\omega_{\pi \circ \rho}) = \omega_{\rho}$. Thus we may assume that S is smooth.

Suppose that for $J \subset [n]$ with $|J| \geq 2$, $\sigma_i = \sigma_j$ for all $i, j \in J$. We may assume that $J = \{1, 2, \dots, m\}$ for some $m \leq n$. After pulling-back along $\chi_J : \overline{M}_{0,\mathcal{A}'} \rightarrow \overline{M}_{0,\mathcal{A}}$ (see Section 2.2), we may assume that $(\pi : S \rightarrow B, \sigma_1, \dots, \sigma_n)$ is a family of $\mathcal{A}'$ -stable curves $(\pi : S \rightarrow B, \sigma_m, \sigma_{m+1}, \dots, \sigma_n)$ with $|J| - 1$ additional sections $\sigma_1, \sigma_2, \dots, \sigma_{m-1}$. By the induction hypothesis, $2\omega_{\pi} + \sum_{i=m}^n \sigma_i$ is effective.

So $2\omega_\pi + \sum_{i=1}^n \sigma_i = (2\omega_\pi + \sum_{i=m}^n \sigma_i) + \sum_{i=1}^{m-1} \sigma_i$ is effective, too. Thus we may assume that all sections are distinct.

After taking several blow-ups along points where two or more sections meet, we obtain a family of $(1, \dots, 1)$ -semi-stable curves $(\pi_1 : S_1 \rightarrow B, \sigma_1^1, \dots, \sigma_n^1)$.

Let $\rho_1 : S_1 \rightarrow S$ be the blow-up. If there exist (-1) curves with exactly 2 sections, after contracting these (-1) curves by blowing-down, we get a family $(\pi_2 : S_2 \rightarrow B, \sigma_1^2, \dots, \sigma_n^2)$ of $(1/2, \dots, 1/2)$ -semi-stable curves. Let $\rho_2 : S_1 \rightarrow S_2$ be the blow-down morphism. Over S_2 , $2\omega_{\pi_2} + \sum_{i=1}^n \sigma_i^2$ is nef by Proposition 3.3 and thus effective.

$$(9) \quad \begin{array}{ccccc} & & S_1 & & \\ & \swarrow \rho_1 & \downarrow \pi_1 & \searrow \rho_2 & \\ S & & & & S_2 \\ & \searrow \pi & \downarrow & \swarrow \pi_2 & \\ & & B & & \end{array}$$

From $(1/2, \dots, 1/2)$ -stability, we know that for each point in S_2 , at most two sections meet at that point. Let $x_1, \dots, x_k \in S_2$ be points with coincident sections. Then ρ_2 is the blow-up along $x_1, \dots, x_k$. Let $E_1, \dots, E_k$ be the exceptional divisors. By the blow-up formula, $\omega_{\pi_1} = \rho_2^*(\omega_{\pi_2}) + \sum_{j=1}^k E_j$. Also $\sum_{i=1}^n \sigma_i^1 = \rho_2^*(\sum_{i=1}^n \sigma_i^2) - 2 \sum_{j=1}^k E_j$. Thus

$$(10) \quad 2\omega_{\pi_1} + \sum_{i=1}^n \sigma_i^1 = \rho_2^*(2\omega_{\pi_2} + \sum_{i=1}^n \sigma_i^2),$$

so $2\omega_{\pi_1} + \sum_{i=1}^n \sigma_i^1$ is effective.

Finally, $\rho_{1*}(\omega_{\pi_1}) = \omega_\pi$ and $\rho_{1*}(\sigma_i^1) = \sigma_i$ since ρ_1 is a composition of point blow-ups. Thus $2\omega_\pi + \sum_{i=1}^n \sigma_i = \rho_{1*}(2\omega_{\pi_1} + \sum_{i=1}^n \sigma_i^1)$ is a push-forward of an effective divisor. Hence it is effective, too. $\square$

Proof of Proposition 3.2. For the $n = 4$ case, since $\overline{M}_{0,4} \cong \overline{M}_{0,n} \cong \mathbb{P}^1$, $K_{\overline{M}_{0,n}} \cong \mathcal{O}(-2)$ and $\psi_i \equiv \mathcal{O}(1)$, the result is a consequence of a simple direct computation. So we can use induction on the number n of marked points.

To prove the nefness of $\varphi_{\mathcal{A}*}(\Delta_{\mathcal{A}})$, it suffices to show that for every complete irreducible curve $B \rightarrow \overline{M}_{0,\mathcal{A}}$, the restriction of $\varphi_{\mathcal{A}*}(\Delta_{\mathcal{A}})|_B$ has nonnegative degree. By composing with the normalization $B^\nu \rightarrow B$, we may assume that B is smooth.

By equations (4) and (5), it is straightforward to check that

$$(11) \quad \varphi_{\mathcal{A}*}(\Delta_{\mathcal{A}}) = 2\kappa + \sum_{i=1}^n (1 + a_i)\psi_i + \sum_{\substack{i < j \\ a_i + a_j \leq 1}} (a_i + a_j)D_{\{i,j\}}$$

$$(12) \quad = \pi_* \left(2\omega^2 + \sum_{i=1}^n (1 + a_i)(\omega \cdot \sigma_i) + \sum_{\substack{i < j \\ a_i + a_j \leq 1}} (a_i + a_j)(\sigma_i \cdot \sigma_j) \right).$$

For a boundary divisor D_I of nodal curves, let $\eta_I : \overline{M}_{0,\mathcal{A}_I} \times \overline{M}_{0,\mathcal{A}_I^c} \rightarrow D_I \hookrightarrow \overline{M}_{0,\mathcal{A}}$ be the inclusion of boundary. We will use the same notation as in Section 2.2. By

Lemma 2.5 and (11), it is straightforward to check

$$(13) \quad \eta_I^*(\varphi_{\mathcal{A}*}(\Delta_{\mathcal{A}})) = \pi_1^*(\varphi_{\mathcal{A}_I*}(\Delta_{\mathcal{A}_I})) + \pi_2^*(\varphi_{\mathcal{A}_{I^c}*}(\Delta_{\mathcal{A}_{I^c}})).$$

Thus for a curve B supported on a boundary of nodal curves, the degree of $\varphi_{\mathcal{A}*}(\Delta_{\mathcal{A}})$ is nonnegative by induction. Therefore it suffices to check for a family $S \rightarrow B$ of nodal curves over a smooth curve B , whose general fiber is a nonsingular curve.

Note that $\omega \cdot \sigma_i = -\sigma_i^2$ by adjunction and $\sigma_i \cdot \sigma_j = 0$ if $a_i + a_j > 1$. Therefore

$$(14) \quad \begin{aligned} & 2\omega^2 + \sum_{i=1}^n (1 + a_i)(\omega \cdot \sigma_i) + \sum_{\substack{i < j \\ a_i + a_j \leq 1}} (a_i + a_j)(\sigma_i \cdot \sigma_j) \\ &= 2\omega^2 + \sum_{i=1}^n (\omega \cdot \sigma_i) + \sum_{i=1}^n 2a_i(\omega \cdot \sigma_i) + \sum_{i=1}^n a_i \sigma_i^2 + \sum_{i < j} (a_i + a_j)(\sigma_i \cdot \sigma_j) \\ &= (\omega + \sum_{i=1}^n a_i \sigma_i) \cdot (2\omega + \sum_{i=1}^n \sigma_i). \end{aligned}$$

Hence it suffices to check that $\deg \pi_*((\omega + \sum_{i=1}^n a_i \sigma_i) \cdot (2\omega + \sum_{i=1}^n \sigma_i))|_B \geq 0$. By Proposition 3.3, $\omega + \sum_{i=1}^n a_i \sigma_i$ is nef on S . By Lemma 3.4, $2\omega + \sum_{i=1}^n \sigma_i$ is effective on S . Thus the intersection is nonnegative and the result follows. $\square$

Next, we prove the ampleness of $\varphi_{\mathcal{A}*}(\Delta_{\mathcal{A}})$. This is an application of the perturbation technique of Fedorchuk and Smyth introduced in [FS08].

Proposition 3.5. *With the same hypotheses of Proposition 3.2, $\varphi_{\mathcal{A}*}(\Delta_{\mathcal{A}})$ is an ample divisor on $\overline{M}_{0,\mathcal{A}}$.*

Proof. Fix a metric $\|\cdot\|_{\mathcal{A}}$ on $N^1(\overline{M}_{0,\mathcal{A}})$ for each weight datum $\mathcal{A}$. We will prove the following statement: For $\overline{M}_{0,\mathcal{A}}$, there exists $\epsilon_{\mathcal{A}} > 0$ such that $\varphi_{\mathcal{A}*}(\Delta_{\mathcal{A}}) + P$ is nef for every $P \in N^1(\overline{M}_{0,\mathcal{A}})$ satisfying $\|P\|_{\mathcal{A}} < \epsilon_{\mathcal{A}}$. This implies that $\varphi_{\mathcal{A}*}(\Delta_{\mathcal{A}})$ lies in the interior of $\text{Nef}(\overline{M}_{0,\mathcal{A}})$, so by Kleiman's criterion, $\varphi_{\mathcal{A}*}(\Delta_{\mathcal{A}})$ is ample.

We will use induction on n . When $n = 4$, then $\overline{M}_{0,\mathcal{A}} \cong \mathbb{P}^1$ and the result is straightforward.

Let B be an integral complete curve on $\overline{M}_{0,\mathcal{A}}$. Since we consider only the intersection numbers, we may assume B is nonsingular by applying normalization. We will divide it into three cases:

Case 1. B is in a component of nodal boundary.

By (13) and induction hypothesis, when we restrict $\varphi_{\mathcal{A}*}(\Delta_{\mathcal{A}})$ to a component of the boundary of nodal curves, the restriction is ample. So there exists $\epsilon_{\mathcal{A},I} > 0$ such that $\eta_I^*(\varphi_{\mathcal{A}*}(\Delta_{\mathcal{A}}) + P)$ is nef for all $P \in N^1(\overline{M}_{0,\mathcal{A}})$ such that $\|P\|_{\mathcal{A}} < \epsilon_{\mathcal{A},I}$.

Case 2. A general point of B parametrizes a smooth curve, and there exists $J \subset [n]$ with $|J| \geq 2$ such that $\sigma_i = \sigma_j$ for all $i, j \in J$.

We may assume that J is maximal among such subsets. In this case, B is contained in the image of $\chi_J : \overline{M}_{0,\mathcal{A}'} \rightarrow \overline{M}_{0,\mathcal{A}}$ defined in Section 2.2. Let p be the

unique index of $\mathcal{A}' = (a'_j)$ replacing indices in J . Then by (5) and Lemma 2.6,

(15)

$$\begin{aligned}
 \chi_J^*(\varphi_{\mathcal{A}*}(\Delta_{\mathcal{A}})) &= \chi_J^*\left(-2D_{\text{nod}} + \sum_{i=1}^n (1+a_i)\psi_i + \sum_{\substack{i < j \\ a_i + a_j \leq 1}} (a_i + a_j)D_{\{i,j\}}\right) \\
 &= -2D_{\text{nod}} + \sum_{i \in J^c} (1+a_i)\psi_i + \sum_{i \in J} (1+a_i)\psi_p + \sum_{\substack{i < j, i, j \in J^c \\ a_i + a_j \leq 1}} (a_i + a_j)D_{\{i,j\}} \\
 &\quad + \sum_{\substack{i \in J, j \in J^c \\ \sum_{i \in J} a_i + a_j \leq 1}} (a_i + a_j)D_{\{p,j\}} - \sum_{i < j, i, j \in J} (a_i + a_j)\psi_p \\
 &= -2D_{\text{nod}} + \sum_{i \in J^c} (1+a_i)\psi_i + (1 + \sum_{j \in J} a_j)\psi_p + (|J| - 1)\psi_p + \sum_{\substack{i < j, i, j \in J^c \\ a_i + a_j \leq 1}} (a_i + a_j)D_{\{i,j\}} \\
 &\quad + \sum_{\substack{j \in J^c \\ \sum_{i \in J} a_i + a_j \leq 1}} \left(\left(\sum_{i \in J} a_i \right) + a_j \right) D_{\{p,j\}} + (|J| - 1) \sum_{\substack{j \in J^c \\ \sum_{i \in J} a_i + a_j \leq 1}} a_j D_{\{p,j\}} - (|J| - 1) \left(\sum_{i \in J} a_i \right) \psi_p \\
 &= \varphi_{\mathcal{A}'*}(\Delta_{\mathcal{A}'}) + (|J| - 1) \left(\left(1 - \sum_{i \in J} a_i \right) \psi_p + \sum_{\substack{j \in J^c \\ \sum_{i \in J} a_i + a_j \leq 1}} a_j D_{\{p,j\}} \right) \\
 &= \varphi_{\mathcal{A}'*}(\Delta_{\mathcal{A}'}) + (|J| - 1) \pi_* \left((\omega + \sum a'_j \sigma_j) \cdot \sigma_p \right).
 \end{aligned}$$

The index of the first sum in the third line follows from the fact that $D_{\{i,j\}}$ for $i \in J, j \notin J$ meets $\chi_J(\overline{M}_{0,\mathcal{A}'})$ only if $\sum_{i \in J} a_i + a_j \leq 1$.

By induction hypothesis, $\varphi_{\mathcal{A}'*}(\Delta_{\mathcal{A}'})$ is ample. Since $\omega + \sum a'_j \sigma_j$ is nef by Proposition 3.2, the second term in the last line of (15) is nonnegative on B (see also [Fed10, Theorem 1]). Hence there exists $\epsilon_{\mathcal{A},J} > 0$ such that $\chi_J^*(\varphi_{\mathcal{A}*}(\Delta_{\mathcal{A}}) + P)$ is nef for all $P \in N^1(\overline{M}_{0,\mathcal{A}})$ with $\|P\|_{\mathcal{A}} < \epsilon_{\mathcal{A},J}$.

Case 3. Otherwise.

In this case, a general point of B parametrizes a smooth curve. Note that there exists $\delta > 0$ such that every $\mathcal{A} = (a_1, \dots, a_n)$ -stable curve is also $\mathcal{A}_\delta = (a_1 - \delta, \dots, a_n - \delta)$ -stable. Therefore $\overline{M}_{0,\mathcal{A}} = \overline{M}_{0,\mathcal{A}_\delta}$ and $\varphi_{\mathcal{A}} = \varphi_{\mathcal{A}_\delta}$, so $\varphi_{\mathcal{A}*}(\Delta_{\mathcal{A}_\delta})$ is nef by Proposition 3.2. Thus

$$\begin{aligned}
 \varphi_{\mathcal{A}*}(\Delta_{\mathcal{A}}) &= \varphi_{\mathcal{A}*}(K_{\overline{M}_{0,n}} + \sum_{i=1}^n a_i \psi_i) \\
 &= \varphi_{\mathcal{A}*}(K_{\overline{M}_{0,n}} + \sum_{i=1}^n (a_i - \delta) \psi_i) + \delta \varphi_{\mathcal{A}*}(\psi) = \varphi_{\mathcal{A}*}(\Delta_{\mathcal{A}_\delta}) + \delta \varphi_{\mathcal{A}*}(\psi).
 \end{aligned}$$

On $\overline{M}_{0,n}$, $\psi = \sum_{j=2}^{\lfloor n/2 \rfloor} \frac{j(n-j)}{n-1} D_j$ by Lemma 2.9. Thus $\varphi_{\mathcal{A}*}(\Delta_{\mathcal{A}})$ is a sum of a nef divisor $\varphi_{\mathcal{A}*}(\Delta_{\mathcal{A}_\delta})$ and an effective divisor $\delta \varphi_{\mathcal{A}*}(\psi)$ supported on the boundary. Note that ψ and $\varphi_{\mathcal{A}*}(\psi)$ are positive linear combinations of all boundary components. So there exists $\epsilon_{\mathcal{A},0} > 0$ such that for $P \in N^1(\overline{M}_{0,\mathcal{A}})$ with $\|P\|_{\mathcal{A}} < \epsilon_{\mathcal{A},0}$, $\delta \varphi_{\mathcal{A}*}(\psi) + P$ is an effective sum of boundary divisors. Since B intersects with

the complement of boundary divisors, $(\delta\varphi_{\mathcal{A}*}(\psi) + P) \cdot B \geq 0$. Therefore B intersects nonnegatively with $\varphi_{\mathcal{A}*}(\Delta_{\mathcal{A}}) + P = \varphi_{\mathcal{A}*}(\Delta_{\mathcal{A}_s}) + (\delta\varphi_{\mathcal{A}*}(\psi) + P)$, for every P satisfying $\|P\|_{\mathcal{A}} < \epsilon_{\mathcal{A},0}$.

Note that there exist only finitely many strata on $\overline{M}_{0,\mathcal{A}}$. So if we take $\epsilon_{\mathcal{A}}$ to be the minimum among $\epsilon_{\mathcal{A},0}$, $\epsilon_{\mathcal{A},I}$ and $\epsilon_{\mathcal{A},J}$, $\varphi_{\mathcal{A}*}(\Delta_{\mathcal{A}}) + P$ is nef for all $P \in N^1(\overline{M}_{0,\mathcal{A}})$ such that $\|P\|_{\mathcal{A}} < \epsilon_{\mathcal{A}}$. $\square$

Next, we prove item (2) of Theorem 1.4. In this case, Kapranov's morphisms $\pi_{\mathcal{A}} : \overline{M}_{0,n} \rightarrow (\mathbb{P}^1)^n //_L SL(2)$ for any effective ample linearization $L = \mathcal{O}(a_1, \dots, a_n)$ plays the same role as $\varphi_{\mathcal{A}}$ ([Kap93]).

Theorem 3.6. *Assume that $n \geq 5$. Let $\mathcal{A} = (a_1, \dots, a_n)$ be a weight datum satisfying $\sum_{i=1}^n a_i = 2$. Then the log canonical model $\overline{M}_{0,n}(K_{\overline{M}_{0,n}} + \sum a_i \psi_i)$ is isomorphic to $(\mathbb{P}^1)^n //_L SL(2)$, where $L = \mathcal{O}(a_1, \dots, a_n)$.*

Proof. For each subset $I \subset [n]$, set $w_I := \sum_{i \in I} a_i$. Let S be the set of $I \subset [n]$ such that

- (1) $2 \leq |I| \leq n-2$,
- (2) $w_I < w_{I^c}$ or $w_I = w_{I^c}$, $|I| < |I^c|$ or $w_I = w_{I^c}$, $|I| = |I^c|$, $1 \in I$.

So there is a bijection between S and the set of irreducible components D_I of the boundary divisor of $\overline{M}_{0,n}$. Set $T = \{I \subset [n] | w_I \leq 1, 2 \leq |I| \leq n-2\}$ as before. Define

$$(16) \quad \Delta'_{\mathcal{A}} := (n-4) \sum_{I \in S} \left(-\binom{|I|}{2} \frac{2}{(n-1)(n-2)} + \frac{|I|-1}{n-2} w_I \right) D_I.$$

Then by Lemmas 2.8 and 2.9, it is straightforward to check that $\Delta_{\mathcal{A}} - \Delta'_{\mathcal{A}}$ is equal to the right side of (7).

The morphism $\pi_{\mathcal{A}}$ contracts all the boundary divisors except D_I with $|I| = 2$. The coefficient of D_I in $\Delta_{\mathcal{A}} - \Delta'_{\mathcal{A}}$ is nonnegative if $|I| \geq 3$ (since $w_I \leq 1$) and zero if $|I| = 2$. Thus $\Delta_{\mathcal{A}} - \Delta'_{\mathcal{A}}$ is also effective and supported on the exceptional locus of $\pi_{\mathcal{A}}$. Therefore, by the same argument as in the proof of Theorem 3.1, $\overline{M}_{0,n}(\Delta_{\mathcal{A}}) \cong \overline{M}_{0,n}(\Delta'_{\mathcal{A}})$.

For a partition $I_1 \sqcup I_2 \sqcup I_3 \sqcup I_4 = [n]$, set $w_j = w_{I_j} = \sum_{i \in I_j} a_i$. We may assume that $w_1 \leq w_2 \leq w_3 \leq w_4$. By Lemma 2.10 it is straightforward to check

$$(17) \quad \Delta'_{\mathcal{A}} \cdot F_{I_1, I_2, I_3, I_4} = \begin{cases} 0, & w_4 \geq 1, \\ (n-4)(1-w_4), & w_4 \leq 1 \text{ and } w_1 + w_4 \geq 1, \\ (n-4)w_1, & w_4 \leq 1 \text{ and } w_1 + w_4 \leq 1. \end{cases}$$

These intersection numbers are proportional to those of $\pi_{\mathcal{A}}^*(\mathcal{O}(a_1, \dots, a_n) // SL(2))$ in [AS08, Lemma 2.2]. Since $N_1(\overline{M}_{0,n})$ is generated by F-curves, $\Delta'_{\mathcal{A}}$ is proportional to the pull-back of the canonical ample divisor $\mathcal{O}(a_1, \dots, a_n) // SL(2)$ on $(\mathbb{P}^1)^n //_L SL(2)$. Therefore $\overline{M}_{0,n}(\Delta_{\mathcal{A}}) \cong (\mathbb{P}^1)^n //_L SL(2)$. $\square$

Remark 3.7. Theorem 3.1 shows an interesting relation between log canonical models of stable pointed rational curves parametrized by $\overline{M}_{0,n}$ and that of the parameter space $\overline{M}_{0,n}$. Let $(C, x_1, \dots, x_n)$ be a stable pointed rational curve. Then the log canonical model $C(\omega_C + \sum a_i x_i)$ is an $\mathcal{A}$ -stable curve. More precisely, it is $\varphi_{\mathcal{A}}(C, x_1, \dots, x_n)$. The same weight datum determines the log canonical model of the parametrized curve $(C, x_1, \dots, x_n)$ and that of the parameter space $\overline{M}_{0,n}$ itself.

Remark 3.8. Suppose that the weight datum $\mathcal{A} = (a_1, \dots, a_n)$ is symmetric, i.e., $a_1 = \dots = a_n = \alpha$ for some $2/n < \alpha \leq 1$. Then by Lemmas 2.8 and 2.9,

$$(18) \quad \psi = \sum_{j=2}^{\lfloor n/2 \rfloor} \frac{j(n-j)}{n-1} D_j = K_{\overline{M}_{0,n}} + 2D.$$

So for $\alpha > 0$,

$$(19) \quad K_{\overline{M}_{0,n}} + \alpha\psi = (1 + \alpha)(K_{\overline{M}_{0,n}} + \frac{2\alpha}{1 + \alpha}D).$$

Therefore the log canonical model of the pair $(\overline{M}_{0,n}, K_{\overline{M}_{0,n}} + \alpha\psi)$ is equal to the log canonical model of the pair $(\overline{M}_{0,n}, K_{\overline{M}_{0,n}} + \frac{2\alpha}{1 + \alpha}D)$. If we substitute $\beta = \frac{2\alpha}{1 + \alpha}$, then we obtain Theorem 1.2, except the range of bigness of the divisor $K_{\overline{M}_{0,n}} + \beta D$. Hence Theorem 1.4 is a generalization of Simpson's theorem (Theorem 1.2).

Remark 3.9. In [Kee92], Keel proved that

$$\text{rank Pic}(\overline{M}_{0,n}) = \dim N^1(\overline{M}_{0,n}) = 2^{n-1} - \binom{n}{2} - 1.$$

This dimension increases exponentially, so one can expect that the whole picture of the birational geometry of $\overline{M}_{0,n}$ is extremely complicated. The moduli spaces $\overline{M}_{0,\mathcal{A}}$ give a family of birational models for $\overline{M}_{0,n}$. These models are smooth, are the targets of birational morphisms from $\overline{M}_{0,n}$ which are smooth blow-downs, and, most importantly, are moduli spaces for another moduli problem. But from Theorem 3.1, one can conclude that this family of birational models of $\overline{M}_{0,n}$ are detected by only an n -dimensional subcone of the effective cone of $\overline{M}_{0,n}$. So it seems that there are still many more birational models of $\overline{M}_{0,n}$ to be discovered.

Remark 3.10. Let $S = \{I \subset [n] \mid 2 \leq |I| \leq \lfloor n/2 \rfloor, 1 \in I \text{ if } |I| = n/2\}$ be the standard index set of boundary divisors. A divisor Δ on $\overline{M}_{0,n}$ is called *log canonical* if

$$\Delta = r(K_{\overline{M}_{0,n}} + \sum_{I \in S} c_I D_I)$$

for some $r > 0$ and $0 \leq c_I \leq 1$ (compare to the definition in [AGS10, Definition 6.2]). If $c_I = c_J$ for $I, J \in S$ such that $|I| = |J|$, then we say Δ is *symmetrically log canonical*. For a divisor Δ which is numerically equivalent to a log canonical divisor, it is nef if and only if Δ intersects with F-curves nonnegatively ([FG03, Theorem 4]). So if $\varphi_{\mathcal{A}}^* \varphi_{\mathcal{A}*}(\Delta_{\mathcal{A}})$ in (6) is log canonical, computing intersection numbers with F-curves is sufficient to prove Theorem 3.1.

But in general, $\varphi_{\mathcal{A}}^* \varphi_{\mathcal{A}*}(\Delta_{\mathcal{A}})$ is not numerically equivalent to a log canonical divisor. For example, if $n = 15$ and $\mathcal{A} = (1/6, 1/6, \dots, 1/6)$, then by using the computer algebra system, we can check that $\varphi_{\mathcal{A}}^* \varphi_{\mathcal{A}*}(\Delta_{\mathcal{A}})$ is not symmetrically log canonical. By Proposition 3.11, it is not numerically equivalent to a log canonical divisor. Thus Theorem 3.1 cannot be proved by checking intersection numbers with F-curves.

Proposition 3.11 is due to the referee.

Proposition 3.11. *Let Δ be an S_n -invariant divisor on $\overline{M}_{0,n}$. Suppose that Δ is numerically equivalent to a log canonical divisor. Then Δ is symmetrically log canonical.*

Proof. By hypothesis, we have

$$(20) \quad \Delta + \sum a_i R_i = r(K_{\overline{M}_{0,n}} + \sum c_I D_I),$$

where R_i denote the Rulla relations ([Rul06, Lemma 2.1]), $0 \leq c_I \leq 1$ for all I . The summation is over the set of boundary divisors.

The Rulla relations form an irreducible S_n -module ([MS11, Proposition 2.3]). Thus $\sum_{\sigma \in S_n} \sigma R_i = 0$ for all i . Therefore by symmetrizing both sides of (20), we obtain

$$\Delta = r(K_{\overline{M}_{0,n}} + \sum_{j=2}^{\lfloor n/2 \rfloor} \frac{1}{\binom{n}{j}} (\sum_{|I|=j} c_I) D_j).$$

Since $0 \leq c_I \leq 1$, we have $0 \leq \frac{1}{\binom{n}{j}} (\sum_{|I|=j} c_I) \leq 1$; hence Δ is symmetrically log canonical. $\square$

ACKNOWLEDGEMENTS

It is a great pleasure for the author to thank his advisor, Young-Hoon Kiem. Originally, finding a universal formula for log canonical models of $\overline{M}_{0,n}$ was a question raised by him. Without his patience and advice, it would have been impossible for the author to finish this project. The author would also like to thank Maksym Fedorchuk and the referee for invaluable comments and suggestions.
