ON THE CLASS NUMBER OF THE CYCLOTOMIC NUMBER FIELD

$$k(e^{2\pi i/p^n})^*$$

BY

JACOB WESTLUND

Introduction.—The object of the present paper is to investigate the relation between the class numbers of the cyclotomic number fields $k(e^{2\pi i/p^n})$ and $k(e^{2\pi i/p^{n-1}})$ when p is any odd prime and $n \geq 2$. The method is similar to the method used by WEBER † for the case $p = 2$.

Let $m = p^n$, $m' = p^{n-1}$, $\mu = \phi(m) = p^{n-1}(p-1)$, $\mu' = \phi(m') = p^{n-2}(p-1)$, $r = e^{2\pi i/p^n}$, $r' = e^{2\pi i/p^{n-1}}$. Denote by h and h' the class numbers of $k(r)$ and $k(r')$ respectively, and set

$$h = h' H.$$

We also set $h = kh_1$, $h' = k'h'_1$, $k = k'A$, $h_1 = h'_1 B$ and hence

$$H = AB,$$

where h_1 and h'_1 are the class numbers of the real fields $k(r + r^{-1})$ and $k(r' + r'^{-1})$ respectively. Also let

$$E = DE',$$

E and E' being the regulators of $k(r + r^{-1})$ and $k(r' + r'^{-1})$ respectively.

I. Expressions for A and B .

If we set $\theta = e^{2\pi i/\mu}$ and $t \equiv g^v$, mod. m , g being a primitive root of m , we have the following expressions for k and h_1 : ‡

$$(1) \quad k = \frac{p^{\frac{1+p^{n-1}[n(p-1)-1]}{4} + n}}{2^{\frac{p^{n-1}(p-1)}{2} - 1} \pi^{\frac{p^{n-1}(p-1)}{2}}} \prod_s X_1^{(s)},$$

* Presented to the Society at the Evanston meeting, September 2-3, 1902. Received for publication August 25, 1902.

† WEBER, *Lehrbuch der Algebra*, 2d ed., vol. 2, pp. 796-818.

‡ WEBER, *Lehrbuch der Algebra*, 2d ed., vol. 2, p. 793.

$$(2) \quad h_1 = \frac{p^{\frac{-1+p^{n-1}[n(p-1)-1]}{4}}}{2^{\frac{p^n-1(p-1)}{2}-1}} \prod_s X_2^{(s)},$$

where

$$X_1^{(s)} = \frac{\pi i^{-1}}{m^2} \sum_{\lambda}^{m-1} \lambda f_s(r^\lambda), \quad X_2^{(s)} = -\frac{1}{2m} \sum_{\lambda}^{m-1} f_s(r^\lambda) \log \left(\sin \frac{\lambda\pi}{m} \right)^2,$$

$$f_s(r^\lambda) = \sum_t \theta^{sy} r^{\lambda t}.$$

Here t runs through a complete residue system with respect to the modulus m except multiples of p . In (1), s takes all odd and in (2), all even values less than μ except zero.

If we denote by Y the function X corresponding to the field $k(r')$, then we have for every $s < \mu'$

$$(3) \quad X^{(ps)} = Y^{(s)}.$$

For

$$\begin{aligned} f_{ps}(r^\lambda) &= \sum_t \theta^{psy} r^{\lambda t} = \sum_t \theta'^{sy} r^{\lambda t} & (\theta' = \theta^p) \\ &= \sum_{t'} \theta'^{sy} r^{\lambda t'} (1 + \rho^\lambda + \dots + \rho^{(p-1)\lambda}) & (\rho = e^{2\pi i/p}), \end{aligned}$$

where t' runs through a complete residue system, mod. m' , except multiples of p .

Hence

$$f_{ps}(r^\lambda) = 0, \quad \text{if} \quad \lambda \not\equiv 0, \quad \text{mod. } p$$

and

$$f_{ps}(r^\lambda) = p \sum_{t'} \theta'^{sy'} r'^{\lambda' t'}, \quad \text{if} \quad \lambda \equiv 0, \quad \text{mod. } p.$$

In the last expression $\lambda = p\lambda'$ and $g' \equiv t' \text{ mod. } m'$. From this (3) follows directly.

To obtain expressions for k' and h'_1 , we replace, in (1) and (2), n by $n-1$ and X by Y . Making use of (3) we then get after a few reductions the following expressions for the factors A and B :

$$(4) \quad A = \frac{p^{\frac{p^{n-2}(p-1)^2 n}{4} + 1}}{2^{\frac{p^{n-2}(p-1)^2}{2}} \cdot \pi^{\frac{p^{n-2}(p-1)^2}{4}}} \prod_s X_1^{(s)},$$

$$(5) \quad B = \frac{p^{\frac{np^{n-2}(p-1)^2}{4}}}{2^{\frac{p^{n-2}(p-1)^2}{2}} D} \prod_s X_2^{(s)}.$$

In (4), s takes all odd and in (5), all even values less than μ except multiples of p .

II. The factor A .

1. *Simplification of the expression for A .* We will now show how the expression for A given above may be simplified so as to make it more convenient for numerical computation and also prove that A is an integer.

Consider the function $f_s(r^\lambda)$. Two cases present themselves: $\lambda \not\equiv 0, \text{ mod. } p$, and $\lambda \equiv 0, \text{ mod. } p$.

1°. $\lambda \not\equiv 0, \text{ mod. } p$. In this case, observing that

$$\theta^{s\gamma} = \theta^{s \text{ ind } t} = \frac{\theta^{s \text{ ind } (\lambda t)}}{\theta^{s \text{ ind } \lambda}},$$

we get, after replacing λt by t ,

$$(6) \quad f_s(r^\lambda) = \theta^{-s \text{ ind } \lambda} \sum_t \theta^{s \text{ ind } t} r^t = \theta^{-s\gamma_1} (\theta^s, r),$$

where $\gamma_1 = \text{ind } \lambda$.

2°. $\lambda \equiv 0, \text{ mod. } p$. In this case set $\lambda = p\lambda$, and we have

$$(7) \quad f_s(r^\lambda) = \sum_t \theta^{s\gamma_r p\lambda_1 t} = \sum_{\gamma}^{1, \mu} \theta^{s\gamma + (p-1)\lambda_1 t}.$$

Let a be the greatest common divisor of s and $p-1$, and set $p-1 = ab$. Then the exponents in (7) fall into a groups which are congruent to each other mod. μ , the elements of each group being incongruent mod. μ . Hence

$$f_s(r^\lambda) = a \sum_{\gamma} \theta^{s\gamma + (p-1)\lambda_1 t},$$

where

$$\gamma = 1, 1+a, 1+2a, \dots, 1+(p^{n-1}b-1)a.$$

But the μ/a terms under the summation sign are the roots of the equation

$$x^{p^{n-1}b} - 1 = 0,$$

and hence

$$(8) \quad f_s(r^\lambda) = 0.$$

Making use of (6) and (8), which hold for both even and odd values of s , we get

$$(9) \quad X_1^{(s)} = \frac{\pi i}{m^2} (\theta^s, r) \phi(\theta^s);$$

if we set

$$(10) \quad \phi(\theta^s) = \sum_{\lambda} \lambda \theta^{-s\gamma},$$

where $\gamma = \text{ind } \lambda$ and $\lambda = 1, 2, \dots, m-1$ except multiples of p .

The function $\phi(\theta^s)$ may however be simplified. Since

$$(m - \lambda) \theta^{-s \text{ ind } (m-\lambda)} = - (m - \lambda) \theta^{-s \text{ ind } \lambda},$$

we get

$$(11) \quad \phi(\theta^s) = \sum_{\lambda} (2\lambda - m) \theta^{-s\gamma},$$

where $\lambda = 1, 2, \dots, (m-1)/2$ except multiples of p . For A we then obtain, observing that

$$\theta^{\mu-s} = \theta^{-s}(\theta^s, r)(\theta^{-s}, r) = (-1)^s p^n, *$$

the following expression

$$(12) \quad A = \frac{\prod_s \phi(\theta^s)}{2^{\frac{p^n-2(p-1)^2}{2}} p^{\frac{p^n-2(p-1)^2n}{2}-1}},$$

where s takes all odd values less than μ .

2. *Proof that A is an integer.* It is evident that $\phi(\theta^s)$ is an algebraic integer in the field $k(\theta)$. Now we have

$$\phi(\theta^s) = \sum_i^{1, \mu} \lambda_i \theta^{-is} = \sum_i^{1, \mu/2} (\lambda_i - \lambda_{\mu/2+i}) \theta^{-is} \quad (i = \text{ind } \lambda_i).$$

But since

$$\lambda_{\mu/2+i} \equiv g^{\mu/2+i} \equiv -g^i \equiv -\lambda_i \pmod{m},$$

we have

$$\lambda_{\mu/2+i} = m - \lambda_i;$$

and hence

$$\phi(\theta^s) = 2 \sum_i^{1, \mu/2} \lambda_i \theta^{-is} - m \sum_{\lambda}^{1, \mu/2} \theta^{-is} = 2 \sum_i^{1, \mu/2} \lambda_i \theta^{-is} + \frac{2m}{1 - \theta^s}$$

or

$$(1 - \theta^s) \phi(\theta^s) = 2 \left[(1 - \theta^s) \sum_i^{1, \mu/2} \lambda_i \theta^{-is} + m \right].$$

But

$$\prod_s (1 - \theta^s) = \frac{\prod_t (1 - \theta^t)}{\prod_{t'} (1 - \theta^{t'})},$$

where $\theta' = \theta^p$, and t and t' take all odd values less than μ and μ' respectively. Hence, the quantities θ^t and $\theta^{t'}$, being the roots of the equations,

$$x^{\mu/2} + 1 = 0 \quad \text{and} \quad x^{\mu'/2} + 1 = 0$$

* WEBER, *Lehrbuch der Algebra*, 2d ed., vol. 2, p. 71.

respectively, it follows that

$$\prod_i (1 - \theta^i) = 1.$$

Hence we see that $\prod \phi(\theta^i)$ is divisible by $2^{p^{n-2}(p-1)^2/2}$.

To prove that $\prod \phi(\theta^i)$ is divisible by p we have

$$(g - \theta^i) \phi(\theta^i) = \sum_{i=1}^{\mu} (g \lambda_i - \lambda_{i+1}) \theta^{-i\mu}.$$

But

$$g \lambda_i \equiv \lambda_{i+1}, \text{ mod. } m;$$

hence

$$(g - \theta^i) \phi(\theta^i) = m \psi(\theta^i),$$

where $\psi(\theta^i)$ is an algebraic integer, and therefore

$$\prod_i (g - \theta^i) \phi(\theta^i) = m^{\frac{p^{n-2}(p-1)^2}{2}} \prod_i \psi(\theta^i).$$

But

$$\prod_i (g - \theta^i) = \frac{\prod_t (g - \theta^t)}{\prod_{t'} (g - \theta^{t'})},$$

where t and t' take all odd values less than μ and μ' respectively. Hence, reasoning as above, we find

$$\begin{aligned} \prod_i (g - \theta^i) &= \frac{g^{\mu/2} + 1}{g^{\mu'/2} + 1} \\ &= g^{\frac{\mu'}{2}(p-1)} - g^{\frac{\mu'}{2}(p-2)} + \dots + 1, \end{aligned}$$

or, since $g^{\mu'/2} \equiv -1, \text{ mod. } m',$

$$\prod_i (g - \theta^i) \equiv p, \text{ mod. } m.$$

We thus see that $\prod (g - \theta^i)$ is divisible by p and by no higher power of p . Therefore $\prod \phi(\theta^i)$ is divisible by $p^{p^{n-2}(p-1)^2/2-1}$ and hence A is an integer.

If we now denote by A_n the factor A corresponding to $m = p^n$, we get the following expression for the first factor k of the class number of $k(r)$:

$$(13) \quad k = k_1 A_2 A_3 \dots A_n,$$

where k_1 is the first factor of the class number of $k(e^{2\pi i/p})$.

III. The factor B .

1. *Simplification of the expression for B .* Making use of (6) and (8), $X_2^{(s)}$ may be written

$$(14) \quad X_2^{(s)} = -\frac{(\theta^s, r)}{m} \sum_{\lambda} \theta^{-s\gamma} \log \sin \frac{\lambda\pi}{m},$$

where $\gamma = \text{ind } \lambda$ and $\lambda = 1, 2, \dots, m-1$ except multiples of p . But since

$$\theta^{-s \text{ind } (m-\lambda)} \log \sin \frac{(m-\lambda)\pi}{m} = \theta^{-s \text{ind } \lambda} \log \sin \frac{\lambda\pi}{m},$$

we obtain

$$(15) \quad X_2^{(s)} = -\frac{2(\theta^s, r)}{m} \sum_{\lambda} \theta^{-s\gamma} \log \sin \frac{\lambda\pi}{m},$$

for $\lambda = 1, 2, \dots, (m-1)/2$ except multiples of p . From this we get after a few reductions the following expression for B :

$$(16) \quad BD = \prod_i \psi(\theta^s);$$

where s takes all even values, less than μ , not divisible by p and

$$(17) \quad \psi(\theta^s) = \sum_i^{0, \frac{\mu}{2}-1} \theta^{-si} \log \sin \frac{\lambda_i \pi}{m} \quad (i = \text{ind } \lambda_i).$$

We will now show how the product $\prod \psi(\theta^s)$ can be expressed in the form of a determinant. We have

$$(18) \quad \begin{aligned} \psi(\theta^s) &= \sum_i^{0, \frac{\mu}{2}-1} \theta^{-si} \log \frac{\sin \frac{\lambda_i \pi}{m}}{\sin \frac{\pi}{m}} + \log \sin \frac{\pi}{m} \sum_i^{0, \frac{\mu}{2}-1} \theta^{-si} \\ &= \sum_i^{0, \frac{\mu}{2}-1} \theta^{-si} \log \tau_i = \sum_i^{0, \frac{\mu}{2}-1} \theta^{-si} l_i, \end{aligned}$$

where $l_i = \log \tau_i$ and

$$\tau_i = \frac{\sin \frac{\lambda_i \pi}{m}}{\sin \frac{\pi}{m}} = r^{\frac{1-\lambda_i}{2}} \frac{1-r^{\lambda_i}}{1-r};$$

or, if we set $\theta^s = \theta_1$, then, since s is even, $\theta_1^{-\mu/2} = 1$ and

$$(19) \quad \psi(\theta^s) = \sum_i^{0, \frac{\mu}{2}-1} \theta_1^{-i} l_i.$$

Then as above $\Pi \psi(\theta^*)$ is expressed by the following determinant whose absolute value we denote by T_2 :

$$(25) \quad \prod_i \psi(\theta^i) = \pm \begin{vmatrix} L_0 & L_1 & \cdots & L_{\frac{\mu'}{2}-1} \\ L_1 & L_2 & \cdots & L_0 \\ \cdot & \cdot & \cdot & \cdot \\ L_{\frac{\mu'}{2}-1} & L_0 & \cdots & L_{\frac{\mu'}{2}-2} \end{vmatrix} = \pm T_2.$$

Hence from (22) and (25) we get

$$(26) \quad BD = \frac{T_1}{T_2}.$$

From (24) it is seen that T_1 may be written

$$\pm T_1 = \begin{vmatrix} L_0 & \cdots & L_{\frac{\mu'}{2}-1} & l_{\frac{\mu'}{2}} & \cdots & l_{\frac{\mu'}{2}-1} \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ L_{\frac{\mu'}{2}-1} & \cdots & L_{\frac{\mu'}{2}-2} & l_{\mu'-1} & \cdots & l_{\frac{\mu'}{2}-2} \\ L_0 & \cdots & L_{\frac{\mu'}{2}-1} & l_{\mu'} & \cdots & l_{\frac{\mu'}{2}-1} \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ L_0 & \cdots & L_{\frac{\mu'}{2}-1} & l_0 & \cdots & l_{\frac{\mu'}{2}-1} \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ L_{\frac{\mu'}{2}-1} & \cdots & L_{\frac{\mu'}{2}-2} & l_{\frac{\mu'}{2}-1} & \cdots & l_{\frac{\mu'}{2}-2} \end{vmatrix}.$$

Introducing the set of units

$$\tau'_i = r^{\frac{\lambda_i - \lambda_i + \mu'/2}{2}} \cdot \frac{1 - r^{\lambda_i + \mu'/2}}{1 - r^{\lambda_i}} = \frac{\sin \frac{\lambda_i + \mu'/2 \cdot \pi}{m}}{\sin \frac{\lambda_i \pi}{m}},$$

with $l'_i = \log \tau'_i$, and making use of the fact that $l'_i = l_{i+\mu'/2} - l_i$, we get

$$T_1 = T_2 \cdot T_3,$$

where

$$T_3 = \pm \begin{vmatrix} l'_0 & l'_1 & \cdots & l'_{(p-1)\frac{\mu'}{2}-1} \\ l'_1 & l'_2 & \cdots & l'_{(p-1)\frac{\mu'}{2}} \\ \cdot & \cdot & \cdot & \cdot \\ l'_{(p-1)\frac{\mu'}{2}-1} & l'_{(p-1)\frac{\mu'}{2}} & \cdots & l'_{(p-1)\frac{\mu'}{2}-2} \end{vmatrix},$$

and therefore

$$BD = T_3.$$

2. *Normal Units.* In order to investigate the character of D , we have to consider the normal * units of $k(r + r^{-1})$. By a normal unit in $k(r + r^{-1})$ we understand a unit $\epsilon(r)$, different from ± 1 , which satisfies

$$(29) \quad \epsilon(r) \epsilon(\rho r) \epsilon(\rho^2 r) \cdots \epsilon(\rho^{p-1} r) = \pm 1,$$

where $\rho = e^{2\pi i/p} = r^{p^{-1}}$. This means that the relative norm of $\epsilon(r)$ in $k(r + r^{-1})$, with respect to $k(r' + r'^{-1})$, is ± 1 .

It is evident that no unit in $k(r' + r'^{-1})$, which is also a unit in $k(r + r^{-1})$, can be a normal unit. The units τ'_i , considered above, are normal units. For

$$\tau'_{i+a \cdot \mu'/2}(r) = \pm \tau'_i(\rho^{(-1)^a A_a} r),$$

where

$$g^{a\mu'/2} = (-1)^a + A_a m';$$

and, since $(-1)^a A_a$ runs through a complete residue system with respect to the modulus p when $a = 0, 1, \dots, p-1$, it follows that

$$(30) \quad \tau'_i(r) \tau'_i(\rho r) \cdots \tau'_i(\rho^{p-1} r) = \pm \prod_{a=0}^{p-1} \tau'_{i+a \cdot \mu'/2}(r) = \pm 1.$$

A system of $\nu = (p-1)\mu'/2$ normal units $\epsilon_0(r), \epsilon_1(r), \dots, \epsilon_{\nu-1}(r)$ is said to be an *independent* system of normal units if

$$\begin{vmatrix} \log |\epsilon_0(r)| & \cdots & \log |\epsilon_{\nu-1}(r)| \\ \log |\epsilon_0(r^g)| & \cdots & \log |\epsilon_{\nu-1}(r^g)| \\ \cdot & \cdot & \cdot \\ \log |\epsilon_0(r^{g^{\nu-1}})| & \cdots & \log |\epsilon_{\nu-1}(r^{g^{\nu-1}})| \end{vmatrix} \neq 0;$$

and the absolute value of the determinant is called the *regulator* of the system $\epsilon_0, \epsilon_1, \dots, \epsilon_{\nu-1}$. The units $\tau'_0, \tau'_1, \dots, \tau'_{\nu-1}$ form such an independent system of normal units; for its regulator, being the determinant T_3 , is evidently different from zero.

Now let $\epsilon_0, \epsilon_1, \dots, \epsilon_{\nu-1}$ be an independent system of normal units and let $L_{i,\kappa} = \log |\epsilon_i(r^{g^\kappa})|$. Then, if $\epsilon'(r)$ be any normal unit and $L'_\kappa = \log |\epsilon'(r^{g^\kappa})|$, we can determine $\xi_0, \xi_1, \dots, \xi_{\nu-1}$ from the system of equations

$$(31) \quad L'_\kappa = \xi_0 L_{0,\kappa} + \xi_1 L_{1,\kappa} + \cdots + \xi_{\nu-1} L_{\nu-1,\kappa} \quad (\kappa = 0, 1, \dots, \nu-1).$$

That this equation also holds for any value of κ follows immediately from (29) and (30). By applying the same reasoning as for independent systems of units

* WEBER, *Lehrbuch der Algebra*, 2d ed., vol. 2, p. 806.

in any algebraic number field* we can prove that $\xi_0, \dots, \xi_{\nu-1}$ are rational, and hence that there exists an independent system of normal units whose regulator is the least possible. Such a system we call a *fundamental system* of normal units, and any normal unit can be written in the form

$$\pm \epsilon_0^{m_0} \epsilon_1^{m_1} \dots \epsilon_{\nu-1}^{m_{\nu-1}},$$

where $\epsilon_0, \epsilon_1, \dots, \epsilon_{\nu-1}$ are a fundamental system and $m_0, m_1, \dots, m_{\nu-1}$ are integers. The regulator of a fundamental normal system is, therefore, a divisor of the regulator of any (independent) system of normal units.

3. *Study of D.* Let $\epsilon_1, \epsilon_2, \dots, \epsilon_{\mu/2-1}$ be a fundamental system of units in $k(r + r^{-1})$, with the conjugate logarithms $\lambda_{1,\kappa}, \lambda_{2,\kappa}, \dots, \lambda_{\mu/2-1,\kappa}$ and regulator E , and let $\epsilon'_1, \epsilon'_2, \dots, \epsilon'_{\mu'/2-1}$ be a fundamental system of units in $k(r' + r'^{-1})$ with the conjugate logarithms $\lambda'_{1,\kappa}, \lambda'_{2,\kappa}, \dots, \lambda'_{\mu'/2-1,\kappa}$ and regulator E' . Also let $\omega_0, \omega_1, \dots, \omega_{\nu-1}$ be a fundamental system of normal units in $k(r + r^{-1})$ with the conjugate logarithms $L_{0,\kappa}, L_{1,\kappa}, \dots, L_{\nu-1,\kappa}$ and regulator T_0 . Then the units

$$(32) \quad \epsilon'_1, \epsilon'_2, \dots, \epsilon'_{\frac{\mu'}{2}-1}, \omega_0, \omega_1, \dots, \omega_{\nu-1}$$

form an independent system of units in $k(r + r^{-1})$. For since

$$\lambda'_{i,\kappa+\mu'/2} = \lambda'_{i,\kappa}$$

and

$$L_{i,0} + L_{i,\mu'/2} + \dots + L_{i,(p-1)\mu'/2} = 0,$$

we get for the regulator R of the system (32),

$$(33) \quad R = p^{\mu'/2-1} E' T_0,$$

which shows that $R \neq 0$ and hence that (32) form an independent system of units.

We can then determine rational numbers $m_{i,\kappa}$ and $M_{i,\kappa}$ such that

$$(34) \quad p\lambda_{i,\kappa} = m_{1,i}\lambda'_{1,\kappa} + \dots + m_{\mu'/2-1,i}\lambda'_{\mu'/2-1,\kappa} + M_{0,i}L_{0,\kappa} + \dots + M_{\nu-1,i}L_{\nu-1,\kappa}$$

$$\left(\kappa = 0, \dots, \frac{\mu}{2} - 2; i = 1, \dots, \frac{\mu}{2} - 1 \right).$$

We now wish to prove that $m_{i,\kappa}$ and $M_{i,\kappa}$ are integers. From (34) we get

$$\lambda_{i,\kappa} + \lambda_{i,\kappa+\mu'/2} + \dots + \lambda_{i+(p-1)\mu'/2} = m_{1,i}\lambda'_{1,\kappa} + \dots + m_{\mu'/2-1,i}\lambda'_{\mu'/2-1,\kappa},$$

and, since

$$\epsilon_i(r)\epsilon_i(r^{\mu'/2}) \dots \epsilon_i(r^{\mu'(p-1)\mu'/2})$$

* WEBER, *Lehrbuch der Algebra*, 2d ed., vol. 2, § 191.

is a unit in $k(r' + r'^{-1})$, it follows that $m_{1,\epsilon}, m_{2,\epsilon}, \dots, m_{\mu'/2-1,\epsilon}$ are integers.

We also obtain from (34)

$$\lambda_{i,\kappa} + \dots + \lambda_{i,\kappa+(p-1)\mu'/2} - p\lambda_{i,\kappa} = -M_{0,\epsilon}L_{0,\kappa} - \dots - M_{\nu-1,\epsilon}L_{\nu-1,\kappa},$$

and since

$$\frac{\epsilon_i(r)\epsilon_i(r^{g^{\mu'}})\dots\epsilon_i(r^{g^{(p-1)\mu'}})}{[\epsilon_i(r)]^p}$$

is a normal unit, it follows that $M_{0,\epsilon}, \dots, M_{\nu-1,\epsilon}$ are integers.

From (34)

$$(35) \quad E = p^{-\frac{\mu}{2}+1} RM,$$

where M is the determinant of the coefficients $m_{i,\kappa}$ and $M_{i,\kappa}$ and hence an integer. Formulae (33) and (35) then give

$$(36) \quad D = p^{(\mu'-\mu)/2} MT_0.$$

We now propose to investigate the character of M . To do this let

$$\begin{aligned} \lambda'_{i,\kappa} &= n_{1,\epsilon}\lambda_{1,\kappa} + \dots + n_{\frac{\mu}{2}-1,\epsilon}\lambda_{\frac{\mu}{2}-1,\kappa} \quad (i=1, 2, \dots, \frac{\mu'}{2}-1), \\ L_{i,\kappa} &= N_{1,\epsilon}\lambda_{1,\kappa} + \dots + N_{\frac{\mu}{2}-1,\epsilon}\lambda_{\frac{\mu}{2}-1,\kappa} \quad (i=0, 1, \dots, \nu-1), \end{aligned}$$

where $n_{i,\kappa}$ and $N_{i,\kappa}$ are integers. Denoting by N the determinant of the coefficients $n_{i,\kappa}$ and $N_{i,\kappa}$, we get

$$R = EN$$

and hence

$$(37) \quad MN = p^{\frac{\mu}{2}-1},$$

i. e., M and N are both powers of p . To determine the power of p by which M is divisible, we determine a system of integers $a_1, a_2, \dots, a_{\mu/2-1}$ without common divisor satisfying the system of equations

$$(38) \quad a_1 m_{i,1} + a_2 m_{i,2} + \dots + a_{\mu/2-1} m_{i,\mu/2-1} = 0 \quad (i=1, 2, \dots, \frac{\mu'}{2}-1).$$

Let

$$a_1 M_{i,1} + a_2 M_{i,2} + \dots + a_{\mu/2-1} M_{i,\mu/2-1} = \xi_i \quad (i=0, 1, \dots, \nu-1),$$

and we have

$$p \sum_{i=1}^{\frac{\mu}{2}-1} a_i \lambda_{i,\kappa} = \xi_0 L_{0,\kappa} + \xi_1 L_{1,\kappa} + \dots + \xi_{\nu-1} L_{\nu-1,\kappa},$$

from which

$$\sum_{i=1}^{\frac{\mu}{2}-1} a_i \lambda_{i,\kappa} + \sum_{i=1}^{\frac{\mu}{2}-1} a_i \lambda_{i,\kappa+\mu'/2} + \dots + \sum_{i=1}^{\frac{\mu}{2}-1} a_i \lambda_{i,\kappa+(p-1)\mu'/2} = 0.$$

Hence we infer that $\epsilon_1^{a_1} \epsilon_2^{a_2} \cdots \epsilon_{\mu/2-1}^{a_{\mu/2-1}}$ is a normal unit and that $\xi_0, \xi_1, \dots, \xi_{\nu-1}$ are integers divisible by p . It is then very easy to show, by applying the same reasoning as in the case $p = 2$,* that M is divisible by $p^{(p-1)\mu'/2}$. Hence if we set

$$M = p^{(p-1)\frac{\mu'}{2} + \sigma},$$

we obtain from (36)

$$(39) \quad D = p^\sigma T_0 \quad \left(\equiv \sigma \equiv \frac{\mu'}{2} - 1 \right).$$

From (28) we then have

$$B = p^{-\sigma} \frac{T_3}{T_0}.$$

where T_3/T_0 is an integer, T_0 being the regulator of a fundamental system of normal units.

If we now denote by B_n the factor B corresponding to $m = p^n$, we get the following expression for the second factor of the class number of $k(r)$:

$$(41) \quad h_1 = h_1'' B_2 B_3 \cdots B_n,$$

where h_1'' is the class number of $k(e^{2\pi i/p} + e^{-2\pi i/p})$.

Comparing our results with those obtained by WEBER for $p = 2$, we notice that, for all values of p , A is an integer and $B = p^{-\sigma} T_3/T_0$, where T_3/T_0 is an integer. For $p = 2$, WEBER proves that $\sigma = 0$ and that both A and T_3/T_0 and hence B are odd numbers. When p is an odd prime, the question whether A and T_3/T_0 are divisible by p or not, and what the value of σ is, remains unsettled. The writer, however, hopes to be able to come back to this question in a following paper.
