APPLICATION OF THE THEORY OF RELATIVE CYCLIC FIELDS TO BOTH CASES OF FERMAT'S LAST THEOREM

BY
H. S. VANDIVER*

If, for p an odd prime,

$$(1) \quad x^p + y^p + z^p = 0$$

is satisfied in integers of x , y , and z prime to each other, $z \not\equiv 0 \pmod{p}$, then in another paper† I gave the relation

$$(2) \quad \prod_{s=1}^{k-1} \prod_{r=1}^{[sp/k]} (x + \alpha^{[1:r]} y) = \alpha^{-k y q(k) / (z+y)} \omega^p,$$

where k is an integer, $1 < k < p$;

$$q(k) = \frac{k^{p-1} - 1}{p};$$

$[s]$ is the greatest integer in s ; ω is an integer in the field $\Omega(\alpha)$, $\alpha = e^{2\pi i/p}$; $[1:r]$ is the integer i in the relation $ri \equiv 1 \pmod{p}$, and if a fraction f/g occurs as an exponent of α , then that exponent is the integer u in the relation $f \equiv gu \pmod{p}$.

In the present paper I shall develop a new line of attack on the Last Theorem by the introduction of power characters in the field $\Omega(e^{2\pi i/p^h})$, h prime to p , in connection with (2).

1. Let n be a prime $\not\equiv 0$ or $1 \pmod{p}$ and suppose that $xyz \not\equiv 0 \pmod{n}$; then

$$(3) \quad x^{n-1} - y^{n-1} \equiv 0 \pmod{n}.$$

If β is a primitive $(n-1)$ th root of unity then in the field $\Omega(\beta)$ we have

$$(n) = q_1 q_2 \cdots q_{\varphi(n-1)}$$

where the q 's are distinct prime ideals, and $\varphi(n-1)$ is the indicator of $n-1$. We may take as one of the q 's the ideal

$$q = (\beta - r, n)$$

* Presented to the Society, September 11, 1925; received by the editors in December, 1925.

† *Annals of Mathematics*, ser. 2, vol. 21 (1919), p. 78.

where r is a primitive root of n . Then (3) gives

$$\prod_{s=0}^{n-2} (x + \beta^s y) \equiv 0 \pmod{q};$$

hence there is an integer a in the set $1, 2, \dots, n-2$, such that

$$(4) \quad x + \beta^a y \equiv 0 \pmod{q}$$

if we note that $x + y \not\equiv 0 \pmod{q}$ since $z \not\equiv 0 \pmod{n}$. Now in the field $\Omega(\alpha\beta)$ we have, if θ is any integer such that (θ) is prime to (p) and the ideal prime $\mathfrak{p}$, with $\mathfrak{p}$ also prime to (p) , if $c = N(\mathfrak{p}) - 1$,

$$\theta^c \equiv 1 \pmod{\mathfrak{p}},$$

$N(\mathfrak{p})$ being the norm of $\mathfrak{p}$, by Fermat's generalized theorem, and consequently there is an integer s such that

$$\theta^{c/p} \equiv \alpha^s \pmod{\mathfrak{p}}$$

since $N(\mathfrak{p}) \equiv 1 \pmod{p}$. Set

$$\left\{ \frac{\theta}{\mathfrak{p}} \right\} = \alpha^s.$$

It follows that θ is congruent to the p th power of an integer in $\Omega(\alpha\beta)$ if and only if

$$\left\{ \frac{\theta}{\mathfrak{p}} \right\} = 1.$$

If the ideal $\mathfrak{P} = \mathfrak{p}'_1 \mathfrak{p}'_2 \dots \mathfrak{p}'_c$ then we use as definition

$$\left\{ \frac{\theta}{\mathfrak{P}} \right\} = \left\{ \frac{\theta}{\mathfrak{p}'_1} \right\} \left\{ \frac{\theta}{\mathfrak{p}'_2} \right\} \dots \left\{ \frac{\theta}{\mathfrak{p}'_c} \right\},$$

the $\mathfrak{p}'$'s being prime ideals in $\Omega(\alpha\beta)$. It follows from the definition that if ψ is an integer in the field $\Omega(\beta)$, then since $n-1 \not\equiv 0 \pmod{p}$,

$$(4a) \quad \left\{ \frac{\psi}{\Omega} \right\} = 1,$$

Ω being an ideal in $\Omega(\beta)$, and if ζ is an integer in $\Omega(\alpha\beta)$ and ζ_i denotes the integer obtained by the substitution (α/α^i) , i prime to p , then

$$(4b) \quad \left\{ \frac{\zeta_i}{\Omega} \right\} = \left\{ \frac{\zeta}{\Omega} \right\}^i.$$

Let

$$q = \mathfrak{p}_1 \mathfrak{p}_2 \dots \mathfrak{p}_d,$$

the $\mathfrak{p}$'s being prime ideals in $\Omega(\alpha\beta)$.

We shall now show that

$$(4c) \quad \left\{ \frac{\alpha}{q} \right\} = \alpha^{q(n)}.$$

Let

$$N(\mathfrak{p}_1) = 1 + w_1 p,$$

$$N(\mathfrak{p}_2) = 1 + w_2 p,$$

$$\dots \dots \dots$$

$$N(\mathfrak{p}_d) = 1 + w_d p;$$

multiplication gives

$$N(q) \equiv 1 + p \sum w \pmod{p^2}, \quad \frac{N(q) - 1}{p} \equiv \sum w \pmod{p}.$$

But $w_s = (N(\mathfrak{p}_s) - 1)/p$, so that

$$\frac{N(q) - 1}{p} \equiv \sum_{s=1}^d \frac{N(\mathfrak{p}_s) - 1}{p} \pmod{p},$$

and (4c) follows immediately from

$$\left\{ \frac{\alpha}{q} \right\} = \prod_{s=1}^d \left\{ \frac{\alpha}{\mathfrak{p}_s} \right\},$$

since

$$\left\{ \frac{\alpha}{q} \right\} = \alpha^{e/p};$$

and

$$N(q) = n^{p-1}.$$

Now take power characters of each member of (2) with respect to q , and since q is prime to (p) and (z) and therefore to $(x + \alpha^e y)$, we have

$$(5) \quad \prod_{r=1}^{k-1} \prod_{s=1}^{[rp/k]} \left\{ \frac{x + \alpha^{[1:r]} y}{q} \right\} = \left\{ \frac{\alpha}{q} \right\}^{-kyq(k)/(s+y)}$$

Now also by (4)

$$\{(x + \alpha^e y)/q\} = \{(x + \beta^a y + y(\alpha^e - \beta^a))/q\} = \{y/q\} \{(\alpha^e - \beta^a)/q\}.$$

By (4a)

$$\left\{ \frac{y}{q} \right\} = 1,$$

so that

$$\left\{ \frac{x + \alpha^e y}{q} \right\} = \left\{ \frac{\alpha^e - \beta^a}{q} \right\}.$$

We also have by (4b)

$$\left\{ \frac{\alpha^a - \beta^a}{q} \right\} = \left\{ \frac{\alpha - \beta^a}{q} \right\}^e.$$

Applying these relations to (5) we obtain with (4c)

$$\left\{ \frac{\alpha - \beta^a}{q} \right\}^{\sum [1:r]} = \alpha^{-k y q(k) q(n) / (x+y)},$$

and since*

$$-kq(k) \equiv \sum [1:r] \pmod{p},$$

we have

$$\left\{ \frac{\alpha - \beta^a}{q} \right\}^{-k q(k)} = \alpha^{-k y q(k) q(n) / (x+y)}.$$

For $k = p-1$ we have $q(k) \not\equiv 0 \pmod{p}$ so that

$$\left\{ \frac{\alpha - \beta^a}{q} \right\} = \alpha^{y q(n) / (x+y)},$$

or since

$$\left\{ \frac{\beta^{-a}}{q} \right\} = 1,$$

then

$$(6) \quad \left\{ \frac{\alpha \beta^{-a} - 1}{q} \right\} = \alpha^{y q(n) / (x+y)}.$$

Note that $(\alpha \beta^{-a} - 1)$ is a unit in $\Omega(\alpha \beta)$.

If we write

$$\left\{ \frac{\alpha \beta^{-a} - 1}{q} \right\} = \alpha^i$$

and $i = \text{ind}(\alpha \beta^{-a} - 1)$, then (6) shows that for some value of a included in the set $1, 2, \dots, n-2$,

$$(7) \quad \text{ind}(\alpha \beta^a - 1) - \frac{y q(n)}{x+y} \equiv 0 \pmod{p}.$$

---

* Vandiver, loc. cit., p. 77, relations 17.

This is equivalent to the relation

$$(7a) \quad \prod_{a=1}^{n-2} (\text{ind}(\alpha\beta^a - 1) - \frac{y}{x+y} q(n)) \equiv 0 \pmod{p}.$$

2. Let us now consider the first case of Fermat's Last Theorem; that is, when $xyz \not\equiv 0 \pmod{p}$. Let $-x/y = t$; then it follows from (1) that the relation

$$(8) \quad \prod_{a=1}^{n-2} ((1-v) \text{ind}(\alpha\beta^a - 1) - q(n)) \equiv 0 \pmod{p}$$

holds if v has any of the six values

$$(9) \quad t, \quad 1-t, \quad \frac{1}{t}, \quad \frac{1}{1-t}, \quad \frac{t}{t-1}, \quad \frac{t-1}{t}.$$

This criterion for (1) when $xyz \not\equiv 0 \pmod{p}$ was obtained under the assumption that xyz was prime to n . If either x , y or z is divisible by n , then it follows by Furtwängler's theorem* that $q(n) \equiv 0 \pmod{p}$. We may then state

THEOREM I. *If $x^p + y^p + z^p = 0$ is satisfied in integers none zero and all prime to the odd prime p , v is any number in the set (9), then for $\alpha = e^{2i\pi/p}$, $\beta = e^{2i\pi/(n-1)}$*

$$q(n) \prod_{a=1}^{n-2} ((1-v) \text{ind}(\alpha\beta^a - 1) - q(n)) \equiv 0 \pmod{p},$$

where $q = (\beta - r, n)$, r is a primitive root of n ,

$$\left\{ \frac{\alpha\beta^a - 1}{q} \right\} = \alpha^i, \quad q(n) = \frac{n^{p-1} - 1}{p},$$

$i = \text{ind}(\alpha\beta^a - 1)$, and n is a prime $\not\equiv 0$ or $1 \pmod{p}$.

The relation (7) is equivalent to

$$(10) \quad (1-t) \text{ind}(\alpha\beta^a - 1) - q(n) \equiv 0 \pmod{p}.$$

Because of (9), there is also an integer b in the set $1, 2, \dots, n-2$ such that

$$(11) \quad t \text{ind}(\alpha\beta^b - 1) - q(n) \equiv 0 \pmod{p}.$$

Eliminating t from (10) and (11) gives

$$\text{ind}(\alpha\beta^a - 1) \text{ind}(\alpha\beta^b - 1) - q(n)(\text{ind}(\alpha\beta^a - 1) + \text{ind}(\alpha\beta^b - 1)) \equiv 0 \pmod{p}.$$

This gives

---

* Wiener Berichte, IIa, 1912, 589-92.

THEOREM II. If $x^p + y^p + z^p = 0$ is satisfied in integers none zero and all prime to the odd prime p , then

$$q(n) \prod_{a,b} (\text{ind } (\alpha\beta^a - 1) \text{ind } (\alpha\beta^b - 1)) \\ - q(n)(\text{ind } (\alpha\beta^a - 1) + \text{ind } (\alpha\beta^b - 1)) \equiv 0 \pmod{p},$$

where a and b each range independently over the integers $1, 2, \dots, n-2$, the other symbols being defined as in Theorem I.

It will be noted that these criteria are independent of x, y and z .

For $n=3$, $q=(3)$, and

$$\left\{ \frac{\alpha\beta - 1}{3} \right\} = \left\{ \frac{-\alpha - 1}{3} \right\} = \left\{ \frac{\alpha + 1}{3} \right\} = \left\{ \frac{\alpha^{\frac{1}{3}}}{3} \right\} \left\{ \frac{\alpha^{\frac{1}{3}} + \alpha^{-\frac{1}{3}}}{3} \right\} = \left\{ \frac{\alpha^{\frac{1}{3}}}{3} \right\} = \alpha^{q(3)/2}.$$

Using this in connection with the criteria of Theorem II, we have

$$q(3) \left(\frac{1}{4}(q(3))^2 - 2 \cdot \frac{1}{2}(q(3))^2 \right) \equiv 0 \pmod{p},$$

whence $q(3) \equiv 0 \pmod{p}$ assuming $p > 3$.

Take $n=5$; then $n-1=4$ and $\Omega(\beta)$ is the field $\Omega(i)$ and we may set $q=(2-i)$. We have

$$(x-y)(x^2+y^2) \equiv 0 \pmod{5}$$

and similarly for (x, z) , (z, y) in lieu of (x, y) . It then follows easily that one of the integers $x-y, x-z, y-z$ is divisible by 5. If $x-y \equiv 0 \pmod{5}$ it follows from (7) that $q(5) \equiv 0 \pmod{p}$ unless $x-y \equiv 0 \pmod{p}$. This is equivalent to the condition that the set (9) satisfies

$$(12) \quad q(5)(t+1)(t-2)(t-\frac{1}{2}) \equiv 0 \pmod{p}.$$

Theorem I also gives

$$(13) \quad q(5) \prod_{a=1}^3 ((1-t) \text{ind } (\alpha\beta^a - 1) - q(5)) \equiv 0 \pmod{p}.$$

As in the case $n=3$ we find

$$\left\{ \frac{\alpha\beta^2 - 1}{q} \right\} = \alpha^{q(5)/2}.$$

Hence if we write

$$\text{ind } (\alpha\beta^a - 1) = I_a$$

we have from (13)

$$(14) \quad q(5)(t+1)((1-t)I_1 - q(5))((1-t)I_3 - q(5)) \equiv 0 \pmod{p}.$$

Now also

$$I_1 + I_3 = \text{ind}(\alpha^2 + 1) \equiv q(5) \pmod{p},$$

so that

$$(14a) \quad I_3 \equiv q(5) - I_1 \pmod{p}.$$

Comparing (12) and (14) it follows that

$$q(5)((1-t)I_1 - q(5))((1-t)I_3 - q(5)) \equiv 0 \pmod{p}$$

for $t=2$ and $t=\frac{1}{2}$, and these values give in each case, using (14a),

$$q(5)(I_1 + q(5))(I_1 - 2q(5)) \equiv 0 \pmod{p}.$$

3. We shall now consider the second case of the Last Theorem. In (7a) assume $y \equiv 0 \pmod{p}$; then we obtain

$$\prod_{a=1}^{n-2} \text{ind}(\alpha\beta^a - 1) \equiv 0 \pmod{p},$$

under the assumption that x, y and z are each prime to n . If x or z is divisible by n then $q(n) \equiv 0 \pmod{p}$, but this does not necessarily hold when $y \equiv 0 \pmod{n}$. Hence

THEOREM III. *If p is an odd prime and $x^p + y^p + z^p = 0$ is satisfied in integers, none zero, $y \equiv 0 \pmod{p}$, with $xz \not\equiv 0 \pmod{p}$, then either $y \equiv 0 \pmod{n}$ or*

$$q(n) \prod_{a=1}^{n-2} \text{ind}(\alpha\beta^a - 1) \equiv 0 \pmod{p},$$

the symbols being defined as in Theorem I.
