q -BERNOULLI AND EULERIAN NUMBERS

BY
L. CARLITZ

1. **Introduction.** In a previous paper [2] the writer defined a set of rational functions η_m of the indeterminate q by means of

$$(1.1) \quad (q\eta + 1)^m = \eta^m \quad (m > 1), \quad \eta_0 = 1, \quad \eta_1 = 0,$$

and a set of polynomials

$$\eta_m(x) = \eta_m(x, q)$$

in q^x by

$$(1.2) \quad \eta_m(x) = ([x] + q^x \eta)^m, \quad \eta_m(0) = \eta_m,$$

where $[x] = (q^x - 1)/(q - 1)$; also

$$(1.3) \quad q^x \beta_m(x) = \eta_m(x) + (q - 1)\eta_{m+1}(x), \quad \beta_m(0) = \beta_m.$$

For $q=1$, β_m reduces to the Bernoulli number B_m , $\beta_m(x)$ reduces to the Bernoulli polynomial $B_m(x)$; η_m however does not remain finite for $m > 1$.

In the present paper we first define polynomials $A_{ms} = A_{ms}(q)$ by means of

$$(1.4) \quad [x]^m = \sum_{s=1}^m A_{ms} \begin{bmatrix} x + s - 1 \\ m \end{bmatrix} \quad (m \geq 1),$$

where

$$\begin{bmatrix} x \\ m \end{bmatrix} = \frac{(q^x - 1)(q^{x-1} - 1) \cdots (q^{x-m+1} - 1)}{(q - 1)(q^2 - 1) \cdots (q^m - 1)}.$$

Alternatively if we define the rational function $H_m = H_m(x, q)$ by means of $H_0 = 1$, $H_1 = 1/(x - q)$,

$$(1.5) \quad (qH + 1)^m = xH^m \quad (m > 1),$$

then we have

$$(1.6) \quad H_m(x, q) = A_m(x, q) / \prod_{s=1}^m (x - q^s),$$

where

$$(1.7) \quad A_m(x, q) = \sum_{s=1}^m A_{ms} x^{s-1} \quad (m \geq 1),$$

Presented to the Society, April 25, 1953; received by the editors February 5, 1953.

and the coefficients are the same as those occurring in (1.4). For $q=1$, A_{ms} and $H_m(x)$ reduce to well known functions; some of the properties of these quantities are stated in §2 below. As Frobenius [3] showed, many of the properties of the Bernoulli and related numbers can be derived from properties of H_m . We shall show that much the same is true in the case of the q analogues.

In [2] a theorem somewhat analogous to the Staudt-Clausen theorem was obtained for β_m (with q an indeterminate). We now show that if p is an odd prime and we put $q=a$, where the rational number a is integral (mod p), then if $a \equiv 1 \pmod{p}$,

$$(1.8) \quad p\beta_m \equiv -1 \pmod{p}$$

provided $p-1 \mid m$; otherwise β_m is integral (mod p). If $a \not\equiv 1 \pmod{p}$ the situation is more complicated. In particular, if a is a primitive root (mod p^2), then β_m is integral (mod p) for $p-1 \nmid m$, while for $p-1 \mid m$ we have

$$p\beta_m \equiv -\frac{1}{k} \pmod{p}, \quad (k = (a^{p-1} - 1)/p).$$

In general the denominator of β_m may be divisible by arbitrarily high powers of p (see Theorem 4 below).

Finally we derive some congruences of Kummer's type for H_m , etc. For example if $q=a$ is integral (mod p) while x is an indeterminate, then

$$H^m(H^w - 1)^r \equiv 0 \pmod{p^m, p^{re}} \quad (p^{e-1}(p-1) \mid w),$$

where after expansion of the left member H^k is replaced by H_k . We also obtain simple congruences for the numbers A_{ms} defined in (1.4). The corresponding results for η_m and β_m are more complicated.

2. **Eulerian numbers.** To facilitate comparison we quote the following formulas from the papers of Frobenius [3] and Worpitzky [5].

$$(2.1) \quad x^m = \sum_{s=1}^m A_{ms} \binom{x+s-1}{m} \quad (m \geq 1),$$

$$(2.2) \quad A_{m+1,s} = (m+2-s)A_{m,s-1} + sA_{m,s},$$

$$(2.3) \quad A_{ms} = \sum_{r=0}^s (-1)^r \binom{m+1}{r} (s-r)^m,$$

$$(2.4) \quad B_m = \frac{1}{m+1} \sum_{r=1}^m (-1)^{m-r-1} \binom{m}{r-1}^{-1} A_{mr}.$$

In the next place if we put

$$(2.5) \quad A_m = A_m(x) = \sum_{s=1}^m A_{ms} x^{s-1},$$

and let

$$H_m = H_m(x) = (x-1)^{-m} R_m(x),$$

then H_m satisfies

$$(2.6) \quad (H+1)^m = xH^m \quad (m \geq 1), \quad H_0 = 1.$$

The connection between H_m and the Bernoulli numbers is furnished by

$$(2.7) \quad \sum_{r=0}^{k-1} \zeta^{-r} B_m \left(\frac{r}{k} \right) = \frac{k^{1-m} \zeta}{1-\zeta} m H_{m-1}(\zeta),$$

where $\zeta^k = 1$, $\zeta \neq 1$. An immediate consequence of (2.7) is

$$(2.8) \quad k^m B_m \left(\frac{r}{k} \right) - B_m = -m \sum_{\zeta \neq 1} \frac{1}{\zeta - 1} H_{m-1}(\zeta),$$

where ζ runs through the k th roots of unity distinct from 1.

We also mention

$$(2.9) \quad H_m = \sum_{r=0}^m (x-1)^{-r} \Delta^r 0^m.$$

3. Some preliminaries. We shall use the notation of [2]; see in particular §2 of that paper. In addition the following remarks will be useful. Let $f(u)$ be a polynomial in q^u of degree $\leq m$. Then the difference equation

$$(3.1) \quad g(u+1) - cg(u) = f(u) \quad (c \neq q^r)$$

has a unique polynomial solution $g(u)$, as can easily be proved by comparison of coefficients. To put the solution in more useful form we rewrite (3.1) as $(E-c)g(u) = f(u)$ and recall that

$$\Delta = E - 1, \quad \Delta^2 = (E-1)(E-q), \quad \Delta^3 = (E-1)(E-q)(E-q^2), \dots$$

In the identity

$$\begin{aligned} \frac{1}{t-z} &= \frac{1}{t-z_1} + \frac{z-z_1}{t-z_1} \frac{1}{t-z_2} + \frac{(z-z_1)(z-z_2)}{(t-z_1)(t-z_2)} \frac{1}{t-z_3} + \dots \\ &\quad + \frac{(z-z_1) \cdots (z-z_n)}{(t-z_1) \cdots (t-z_n)} \frac{1}{t-z} \end{aligned}$$

take $t=c$, $z=E$, $z_s = q^{s-1}$, so that we get

$$\begin{aligned} \frac{1}{c-E} &= \frac{1}{c-1} + \frac{\Delta}{(c-1)(c-q)} + \frac{\Delta^2}{(c-1)(c-q)(c-q^2)} + \dots \\ &\quad + \frac{\Delta^n}{(c-1) \cdots (c-q^{n-1})} \frac{1}{c-E}. \end{aligned}$$

Hence if we take $n > m$, we obtain the following formula for $g(u)$:

$$(3.2) \quad g(u) = \sum_{s=0}^m \frac{\Delta^s f(u)}{(c-1)(c-q) \cdots (c-q^s)}.$$

4. The number A_{ms} . We suppose A_{ms} defined by means of (1.4). Using the identity

$$(q^{m+1} - 1)(q^x - 1) = (q^{m+1-s} - 1)(q^{x+s} - 1) + q^{m+1-s}(q^s - 1)(q^{x+s-m-1} - 1)$$

and multiplying both members of (1.4) by $[x]$, we get

$$\begin{aligned} [x]^{m+1} &= \sum_s A_{ms} \left\{ [m+1-s] \begin{bmatrix} x+s \\ m+1 \end{bmatrix} + q^{m+1-s} [s] \begin{bmatrix} x+s-1 \\ m+1 \end{bmatrix} \right\} \\ &= \sum_s \begin{bmatrix} x+s-1 \\ m+1 \end{bmatrix} \{ [m+2-s] A_{m,s-1} + q^{m+1-s} [s] A_{ms} \}, \end{aligned}$$

which implies the recursion

$$(4.1) \quad A_{m+1,s} = [m+2-s] A_{m,s-1} + q^{m+1-s} [s] A_{ms}.$$

For $q=1$ it is evident that (4.1) reduces to (2.2). As an immediate consequence of (4.1) we infer that A_{ms} is a polynomial in q with positive integral coefficients.

It is easy to show that A_{ms} is divisible by $q^{(m-s)(m-s+1)/2}$. Indeed if we put

$$(4.2) \quad A_{ms} = q^{(m-s)(m-s+1)/2} A_{ms}^*,$$

then (4.1) becomes

$$(4.3) \quad A_{m+1,s}^* = [m+2-s] A_{m,s-1}^* + [s] A_{ms}^*,$$

which proves the stated property. Moreover it follows easily from (4.3) that

$$(4.4) \quad \deg A_{ms}^* = (s-1)(m-s).$$

Indeed assuming the truth of (4.4), we get

$$\begin{aligned} \deg ([m+2-s] A_{m,s-1}^*) &= (m+1-s) + (s-2)(m+1-s) \\ &= (s-1)(m+1-s), \end{aligned}$$

$$\deg ([s] A_{ms}^*) = (s-1) + (s-1)(m-s) = (s-1)(m+1-s),$$

so that

$$\deg A_{m+1,s}^* = (s-1)(m+1-s),$$

which proves (4.4).

The symmetry properties

$$(4.5) \quad A_{m, m-s+1}^* = A_{ms}^*$$

and

$$(4.6) \quad A_{ms}^*(q) = q^{(s-1)(m-s)} A_{ms}^*(q^{-1})$$

will be proved below.

Comparing coefficients of q^{mx} on both sides of (1.4) we get

$$(4.7) \quad \sum_{s=1}^m A_{ms} = [m]! = [m][m-1] \cdots [1].$$

More generally if we expand both sides in powers of q^x and equate coefficients we get

$$(4.8) \quad \begin{bmatrix} m \\ s \end{bmatrix} \sum_{r=1}^m A_{mr} q^{rs} = \binom{m}{s} q^{ms-s(s-1)/2} [m]! \quad (0 \leq s \leq m).$$

The following table of A_{ms}^* , $1 \leq s \leq m \leq 5$, is easily computed by means of (4.3).

	1	2	3	4	5
1	1				
2	1	1			
3	1	$2(q+1)$	1		
4	1	$3q^2+5q+3$	$3q^2+5q+3$	1	
5	1	$4q^3+9q^2+9q+4$	$6q^4+16q^3+22q^2+16q+6$	$4q^3+9q^2+9q+4$	1

5. **A formula for A_{mr}^* .** It is easy to show that if $f(x)$ is a polynomial in q^x of degree $\leq m$,

$$(5.1) \quad f(x) = \sum_{s=0}^m C_{ms} \begin{bmatrix} x+s-1 \\ m \end{bmatrix} \quad (m \geq 1),$$

then

$$(5.2) \quad C_{m0} = (-1)^m q^{m(m+1)/2} f(0),$$

$$(5.3) \quad C_{m, m-r} = \sum_{s=0}^r (-1)^s \begin{bmatrix} m+1 \\ s \end{bmatrix} f(r+1-s) q^{s(s-1)/2}.$$

Since

$$\sum_{s=0}^{m+1} (-1)^s q^{s(s-1)/2} \begin{bmatrix} m+1 \\ s \end{bmatrix} f(x+m+1-s) = 0,$$

we have in particular

$$\sum_{s=0}^{m+1} (-1)^s q^{s(s-1)/2} \begin{bmatrix} m+1 \\ s \end{bmatrix} f(r+1-s) = 0,$$

and (5.3) yields

$$(5.4) \quad C_{mr} = \sum_{s=0}^r (-1)^{m-s} q^{(m-s)(m+1-s)/2} \begin{bmatrix} m+1 \\ s \end{bmatrix} f(s-r),$$

which includes (5.2) also. Thus the coefficients in (5.1) are determined.

If we take $f(x) = [x]^m$, then $C_{mr} = A_{mr}$ and we get after a little manipulation

$$(5.5) \quad A_{mr}^* = q^{r(r-1)/2} \sum_{s=0}^r (-1)^s q^{s(s-1)/2} \begin{bmatrix} m+1 \\ s \end{bmatrix} [r-s]^m;$$

for $q=1$, (5.5) reduces to (2.3).

Replacing q by q^{-1} , (5.5) becomes

$$q^{(r-1)(m-r)} A_{mr}^*(q^{-1}) = q^{(r-1)m+r(r-1)/2} \sum_{s=0}^r (-1)^s q^{s(s-1)/2+e} \begin{bmatrix} m+1 \\ s \end{bmatrix} [r-s]^m,$$

where

$$e = -\frac{s(s-1) - (m+1)(m+2)}{2} + \frac{(m+1-s)(m+2-s)}{2} \\ + \frac{s(s+1)}{2} - (r-s+1)m = -(r-1)m.$$

Hence

$$A_{mr}^*(q) = q^{(r-1)(m-r)} A_{mr}^*(q^{-1}),$$

which is identical with (4.6).

In the next place we observe that exactly as in the proof of (6.2) of [2] we have

$$\sum_{i=0}^m \binom{m}{i} [x]^{i+1} q^{(m-i)x} \frac{\eta_{m-i}}{i+1} + (q^{(m+1)x} - 1) \frac{\eta_{m+1}}{m+1} \\ = \sum_{s=1}^m A_{ms} q^{m-s+1} \begin{bmatrix} x+s-1 \\ m+1 \end{bmatrix}.$$

Divide both sides of this identity by $[x]$ and then put $x=0$. We find that

$$\beta_m = \frac{1}{[m+1]} \sum_{s=1}^m (-1)^{m-s-1} q^{-(m-s)(m-s+1)/2} \begin{bmatrix} m \\ s-1 \end{bmatrix}^{-1} A_{ms}.$$

Using (4.2) and (4.5) this becomes

$$\begin{aligned}\beta_m &= \frac{1}{[m+1]} \sum_{s=1}^m (-1)^{m-s-1} \begin{bmatrix} m \\ s-1 \end{bmatrix}^{-1} A_{ms}^* \\ &= \frac{1}{[m+1]} \sum_{s=1}^m (-1)^s \begin{bmatrix} m \\ s \end{bmatrix}^{-1} A_{ms}^*,\end{aligned}$$

the first of which may be compared with (2.4).

6. **The polynomial $A_m(x)$.** The polynomial $A_m(x) = A_m(x, q)$ is defined in (1.7) for $m \geq 1$; we put $A_0(x) = 1$. Put

$$(6.1) \quad \phi_m(x) = \prod_{s=0}^m (x - q^s)$$

and apply the Lagrange interpolation formula at the points $x = q^s$, $s = 0, 1, \dots, m$. Since

$$\begin{aligned}\phi'(q^s) &= \prod_{i=0}^{s-1} (q^s - q^i) \prod_{j=s+1}^m (q^s - q^j) \\ &= (-1)^{m-s} q^{m-s(s-1)/2} (q-1)^m [s]! [m-s]!,\end{aligned}$$

we get using (4.8)

$$(6.2) \quad A_m(x) = \frac{\phi_m(x)}{(q-1)^m} \sum_{s=0}^m (-1)^{m-s} \begin{pmatrix} m \\ s \end{pmatrix} \frac{1}{x - q^s}.$$

As a first application of (6.2) consider

$$A_m(x^{-1}, q^{-1}) = \frac{x^{-m-1} q^{-m(m+1)/2} \phi_m(x)}{q^{-m} (q-1)^m} \sum_{s=0}^m (-1)^{m-s} \begin{pmatrix} m \\ s \end{pmatrix} \frac{x q^s}{x - q^s},$$

which gives

$$(6.3) \quad x^{m-1} q^{m(m-1)/2} A_m(x^{-1}, q^{-1}) = A_m(x, q) \quad (m \geq 1).$$

Substituting from (1.7) in (6.3) we get

$$q^{m(m-1)/2} \sum_{s=1}^m A_{ms}(q^{-1}) x^{m-s} = \sum_{s=1}^m A_{ms}(q) x^{s-1},$$

which implies

$$(6.4) \quad q^{m(m-1)/2} A_{ms}(q^{-1}) = A_{m, m-s+1}(q).$$

Hence by (4.2) and (4.6), (6.4) becomes

$$q^{m(m-1)/2 - (m-s)(m-s+1)/2 - (s-1)(m-s)} A_{ms}^*(q^{-1}) = q^{s(s-1)/2} A_{m, m-s+1}^*(q),$$

which is the same as (4.5).

7. **The functions $H_m(x)$ and $H_m(u, x)$.** Using (6.2) and (1.6) we get

$$(7.1) \quad (q-1)^m H_m(x) = (x-1) \sum_{s=0}^m (-1)^{m-s} \binom{m}{s} \frac{1}{x-q^s}.$$

We remark that (7.1) implies

$$(7.2) \quad H_m(x) = (x-1) \sum_{r=0}^{\infty} x^{-r-1} [r]^m$$

for $|x| > |q^s|$, $0 \leq s \leq m$. It is also evident that

$$\begin{aligned} (1+qH)^m &= (x-1) \sum_{r=0}^m \binom{m}{r} q^r (q-1)^{-r} \sum_{s=0}^r (-1)^{r-s} \binom{r}{s} \frac{1}{x-q^s} \\ &= (x-1) \sum_{s=0}^m \binom{m}{s} \frac{1}{x-q^s} \sum_{r=s}^m (-1)^{r-s} \binom{m-s}{r-s} q^r (q-1)^{-r} \\ &= (x-1) \sum_{s=0}^m \binom{m}{s} \frac{1}{x-q^s} \frac{q^s}{(q-1)^s} \left(\frac{-1}{q-1} \right)^{m-s} \\ &= (q-1)^{-m} (x-1) \sum_{s=0}^m (-1)^{m-s} \binom{m}{s} \frac{q^s}{x-q^s}, \end{aligned}$$

which implies

$$(7.3) \quad (1+qH)^m = xH^m \quad (m > 1).$$

We have therefore proved (1.5). Alternatively taking (7.3) as definition of H_m one can work back to the earlier formulas obtained for A_{ms} above.

For some purposes it is convenient to define $H_m(u; x) = H_m(u; x, q)$, a polynomial in q^u . We put

$$(7.4) \quad (q-1)^m H_m(u; x) = (x-1) \sum_{s=0}^m (-1)^{m-s} \binom{m}{s} \frac{q^{su}}{x-q^s},$$

so that $H_m(0; x) = H_m(x)$. It follows at once from (7.4) that

$$(7.5) \quad H_m(1-u; x^{-1}, q^{-1}) = (-q)^m H_m(u; x, q)$$

and that

$$(7.6) \quad xH_m(u; x) - H_m(u+1; x) = (x-1)[u]^m.$$

We have also

$$\sum_{r=0}^m \binom{m}{r} q^r H_r(u; x) = H_m(u+1; x),$$

which becomes, using (7.6),

$$(7.7) \quad (1+qH(u; x))^m = xH_m(u; x) - (x-1)[u]^m.$$

For $u=0$, (7.7) reduces to (7.3).

Clearly (7.6) implies

$$(7.8) \quad \sum_{i=0}^{k-1} x^{k-i} [u+i]^m = x^k H_m(u; x) - H_m(u+k; x),$$

which includes (7.2) as a special case.

Since $H_m(u; x)$ is a polynomial in q^u of degree m , the remarks in §3 apply to the difference equation (7.6). In particular, application of (3.2) leads to

$$(7.9) \quad H_m(u; x) = \sum_{s=0}^m \frac{\Delta^s [u]^m}{\psi_s(x)} \quad \left(\psi_s(x) = \prod_{r=1}^s (x - q^r) \right),$$

provided $x \neq q^r$, $r=0, 1, \dots, m$. To simplify the right member of (7.9), we used (2.6) and (3.1) of [2]; thus

$$\Delta^s [u]^m = \sum_{r=s}^m q^{r(r-1)/2} a_{m,r} [r]_s [u]_{r-s} q^{s(u-r+s)}$$

and (7.9) becomes after a little manipulation

$$(7.10) \quad H_m(u; x) = \sum_{r=0}^m q^{r(r-1)/2} a_{m,r} \sum_{s=0}^r \frac{q^{s(u-r+s)}}{\psi_s(x)} [r]_s [u]_{r-s}.$$

If we let $G_r(u)$ denote the inner sum it is clear from (3.2) that

$$xG_r(u) - G_r(u+1) = [u]_r.$$

In (7.10) put $u=0$, then

$$(7.11) \quad H_m(x) = \sum_{r=0}^m q^{r(r-1)/2} \frac{a_{m,r} [r]!}{\psi_r(x)},$$

which for $q=1$ reduces to (2.9).

Using (7.1) and (7.4) it is easy to verify the formula

$$(7.12) \quad H_m(u; x) = \sum_{r=0}^m \binom{m}{r} q^{ru} H_r[u]^{m-r} = (q^u H + [u])^m.$$

Next using (7.12), (7.11), and the explicit formula [2, (6.2)] for $a_{m,s}$ we get

$$(7.13) \quad H_m(u; x) = \sum_{r=0}^m \frac{1}{\psi_r(x)} \sum_{s=0}^r (-1)^s q^{s(s-1)/2} \begin{bmatrix} r \\ s \end{bmatrix} [u+r-s]^m,$$

which is useful later.

8. Connection with $\eta_m(u)$. Using the formula [2, (4.7)]

$$(q-1)^m \eta_m(u) = \sum_{s=0}^m (-1)^{m-s} \binom{m}{s} \frac{s}{[s]} q^{su},$$

we find that

$$\begin{aligned} (q^k - 1)^{m-1} \sum_{r=0}^{k-1} \zeta^{-r} \eta_m \left(u + \frac{r}{k}, q^k \right) &= \sum_{s=0}^m (-1)^{m-s} \binom{m}{s} \frac{\zeta q^{ksu}}{\zeta^{-1} q^s - 1} \\ &= m \sum_{s=0}^{m-1} (-1)^{m-1-s} \binom{m-1}{s} \frac{\zeta q^{ksu+ku-1}}{q^s - \zeta q^{-1}}, \end{aligned}$$

where

$$\zeta^k = 1, \quad \zeta \neq 1.$$

Comparing with (7.4) we have therefore

$$(8.1) \quad [k]^{m-1} \sum_{r=0}^{k-1} \zeta^{-r} \eta_m \left(u + \frac{r}{k}, q^k \right) = \frac{m \zeta q^{ku-1}}{1 - \zeta} H_{m-1}(ku; \zeta q^{-1}),$$

and in particular for $u=0$

$$(8.2) \quad [k]^{m-1} \sum_{r=0}^{k-1} \zeta^{-r} \eta_m \left(\frac{r}{k}, q^k \right) = \frac{m \zeta q^{-1}}{1 - \zeta} H_{m-1}(\zeta q^{-1}),$$

which may be compared with (2.7).

Next using the multiplication formula (see [2, (4.12)]); note that a term is missing in that formula)

$$(8.3) \quad [k]^{m-1} \sum_{r=0}^{k-1} \eta_m \left(u + \frac{r}{k}, q^k \right) = \eta_m(ku, q) + (-1)^m \frac{k - [k]}{(q - 1)^m}$$

together with (8.1) we get

$$\begin{aligned} (8.4) \quad k[k]^{m-1} \eta_m \left(u + \frac{r}{k}, q^k \right) - \eta_m(ku, q) - (-1)^m \frac{k - [k]}{(q - 1)^m} \\ = \frac{m}{q} \sum_{\zeta \neq 1} \frac{\zeta^{r+1}}{1 - \zeta} H_{m-1}(ku; \zeta q^{-1}), \end{aligned}$$

and in particular for $u=0$,

$$\begin{aligned} (8.5) \quad k[k]^{m-1} \eta_m \left(\frac{r}{k}, q^k \right) - \eta_m - (-1)^m \frac{k - [k]}{(q - 1)^m} \\ = \frac{m}{q} \sum_{\zeta \neq 1} \frac{\zeta^{r+1}}{1 - \zeta} H_{m-1}(\zeta q^{-1}). \end{aligned}$$

By means of (1.3) it is easy to write down formulas like (8.1), $\dots$, (8.5) involving β_m .

9. Multiplication formulas. For the polynomial $H_m(u; x)$ we have, using (7.4),

$$\begin{aligned}
 (q^k - 1)^m \sum_{r=0}^{k-1} \zeta^{-r} q^{rt} H_m \left(u + \frac{r}{k}; \zeta q^{-kt}, q^k \right) \\
 = (\zeta q^{-kt} - 1) \sum_{s=0}^m (-1)^{m-s} \binom{m}{s} \frac{q^{ksu}}{\zeta q^{-kt} - q^{ks}} \sum_{r=0}^{k-1} \zeta^{-r} q^{r(s+t)} \\
 = (\zeta - q^{kt}) \sum_{s=0}^m (-1)^{m-s} \binom{m}{s} \frac{q^{ksu}}{\zeta - q^{k(s+t)}} \frac{1 - \zeta^{-k} q^{k(s+t)}}{1 - \zeta^{-1} q^{s+t}}.
 \end{aligned}$$

Consequently if $\zeta^{k-1} = 1$, $\zeta \neq 1$, we get

$$(9.1) \quad [k]^m \sum_{r=0}^{k-1} \zeta^{-r} q^{rt} H_m \left(u + \frac{r}{k}; \zeta q^{-kt}, q^k \right) = \frac{\zeta - q^{kt}}{\zeta - q^t} H_m(ku; \zeta q^{-t}, q),$$

analogous to (8.3).

In the special case $x = -q^{-1}$, the polynomial $\epsilon_m(u)$ of [2, §8] satisfies

$$(9.2) \quad \epsilon_m(u) = H_m(u; -q^{-1}, q);$$

in this case (9.1) becomes ($\zeta = -1$, $t = 1$)

$$(9.3) \quad [k]^m \sum_{r=0}^{k-1} (-q)^r \epsilon_m \left(u + \frac{r}{k}, q^k \right) = \frac{q^k + 1}{q + 1} \epsilon_m(ku, q)$$

for k odd; note that (8.6) of [2] requires a slight correction.

10. Staudt-Clausen theorems for β_m . In [2] a theorem analogous to the Staudt-Clausen theorem was proved for β_m with q indeterminate. Now on the other hand we replace q by a rational number a which is assumed to be integral modulo a fixed prime p . We shall use the representation [2, (6.2)]

$$(10.1) \quad \beta_m = \sum_{s=0}^m (-1)^s a_{m,s} [s]! / [s+1],$$

where

$$(10.2) \quad a_{m,s} = \frac{q^{-s(s-1)/2}}{s!} \sum_{r=0}^s (-1)^r q^{r(r-1)/2} \begin{bmatrix} s \\ r \end{bmatrix} [s-r]^m;$$

the quantity $a_{m,s}$ is a polynomial in q and has occurred in (7.10) and (7.11) above.

Suppose first that $a \equiv 1 \pmod{p}$. Then from (10.1) or [2, §7] it is clear that the s th term in the right member of (10.1) is of the form $u_s = N_s(a)/F_{s+1}(a)$, where $F_{s+1}(x)$ is the cyclotomic polynomial and $N_s(x)$ is a polynomial with integral coefficients. If we recall that $F_k(1) = p$ when $k = p^e$, $e \geq 1$, but $F_k(1) = 1$ otherwise, it is clear that u_s is integral $(\text{mod } p)$ except possibly when $s+1 = p^e$; the same holds also for $F_k(a)$. Now let $s+1 = p^e$. Then by a simple computation it is seen that $[s]!$ is divisible by exactly p^e , where

$$f = (p^e - 1)/(p - 1) - e,$$

while the denominator is divisible by exactly p^e . Since $(p^e - 1)/(p - 1) \geq 2e$ for $e \geq 2$, $p \geq 3$, it follows that u_s is integral in this case. If $e = 1$, $p \geq 3$, we have first $p(a - 1)/(a^p - 1) \equiv 1 \pmod{p}$. As for the numerator of u_{p-1} , it follows readily from (10.2) and

$$\begin{bmatrix} p-1 \\ r \end{bmatrix} \equiv \binom{p-1}{r} \pmod{p}$$

that

$$\begin{aligned} [p-1]!a_{m,p-1} &\equiv \sum_{r=0}^{p-1} (-1)^r \binom{p-1}{r} r^m \\ &\equiv \sum_{r=0}^{p-1} r^m \equiv \begin{cases} -1 \pmod{p} & (p-1 \mid m), \\ 0 \pmod{p} & (p-1 \nmid m). \end{cases} \end{aligned}$$

We have therefore proved

THEOREM 1. *Let $p \geq 3$, $q = a \equiv 1 \pmod{p}$. Then*

$$(10.3) \quad p\beta_m \equiv \begin{cases} -1 \pmod{p} & (p-1 \mid m), \\ 0 \pmod{p} & (p-1 \nmid m). \end{cases}$$

For $p = 2$, the preceding argument shows that all terms in (10.1) are integral $\pmod{2}$ except perhaps u_1 and u_3 . Now

$$u_1 = \frac{a_{m,1}}{[2]} = \frac{1}{a+1},$$

while

$$u_3 = \frac{[3]!a_{m,3}}{[4]} = \frac{a^{-3}}{(a+1)(a^2+1)} \sum_{r=0}^3 (-1)^r a^{r(r-1)/2} \begin{bmatrix} 3 \\ r \end{bmatrix} [3-r]^m.$$

Let $2^e \mid (a+1)$, $2^{e+1} \nmid (a+1)$; then $(a^2 + a + 1)^2 \equiv 1 \pmod{2^{e+1}}$ and

$$\begin{aligned} &\sum_{r=0}^3 (-1)^r a^{r(r-1)/2} \begin{bmatrix} 3 \\ r \end{bmatrix} [3-r]^m \\ &\equiv (a^2 + a + 1)^m - (a^2 + a + 1)(a+1)^m + a(a^2 + a + 1) \\ &\equiv \begin{cases} 0 \pmod{2^{e+1}} & (m \text{ even}), \\ a+1 \pmod{2^{e+1}} & (m \text{ odd}). \end{cases} \end{aligned}$$

Consequently u_3 is integral $\pmod{2}$ for m even while for m odd $2u_3 \equiv 1 \pmod{2}$. This yields the following supplement to Theorem 1.

THEOREM 2. *Let $p = 2$, $q = a \equiv 1 \pmod{2}$; also let $2^e \mid (a+1)$, $2^{e+1} \nmid (a+1)$.*

Then if $e=1$ we have $2\beta_m \equiv 1 \pmod{2}$ for m even ≥ 2 , $2\beta_1 \equiv 1 \pmod{2}$, while β_m is integral $\pmod{2}$ for m odd ≥ 3 . If $e > 1$ then

$$(10.4) \quad 2^e \beta_m \equiv 1 \pmod{2}$$

for all $m \geq 1$.

In particular it is evident from (10.4) that the denominator of β_m may be divisible by arbitrarily high powers of 2.

In the next place we suppose $q = a \not\equiv 1 \pmod{p}$, $p > 2$. It is now convenient to use [2, (5.3)]

$$(10.5) \quad (q-1)^m \beta_m = \sum_{s=0}^m (-1)^{m-s} \binom{m}{s} \frac{s+1}{[s+1]}.$$

We shall assume first that a is a primitive root $\pmod{p^2}$. Clearly in the right member of (10.5) we need consider only those terms in which $p-1 \mid s+1$. Put $a^{p-1} = 1 + kp$, $p \nmid k$. Then

$$a^{(p-1)r} = 1 + rkp + \binom{r}{2} k^2 p^2 + \dots,$$

$$\frac{a^{(p-1)r} - 1}{rp} = k + \frac{1}{2} (r-1) k^2 p + \dots \equiv k \pmod{p}.$$

Thus (10.5) implies

$$(10.6) \quad (a-1)^m p \beta_m \equiv (-1)^m \frac{1}{k} \sum_{r>0} \binom{m}{r(p-1)-1} \pmod{p}.$$

But it is known [4, p. 255] that

$$\sum_{0 < r(p-1) \leq m} \binom{m}{r(p-1)-1} \equiv \begin{cases} -1 \pmod{p} & (p-1 \mid m), \\ 0 \pmod{p} & (p-1 \nmid m). \end{cases}$$

Hence (10.6) implies that p is integral when $m \not\equiv 0 \pmod{p-1}$. This proves

THEOREM 3. Let $p \geq 3$, $q = a$, a a primitive root $\pmod{p^2}$; then β_m is integral $\pmod{p}$ for $p-1 \nmid m$, while

$$(10.7) \quad p \beta_m \equiv -\frac{1}{k} \pmod{p} \quad (p-1 \mid m),$$

where $k = (a^{p-1} - 1)/p$.

It is now clear how to handle the general situation. We may state

THEOREM 4. Let $p \geq 3$, $q = a$, where a belongs to the exponent $e \pmod{p}$, $e > 1$. Put

$$(10.8) \quad a^e = 1 + p^l k \quad (p \nmid k).$$

Then

$$(10.9) \quad (a-1)^m p^l \beta_m \equiv \frac{e}{k} \sum_{r \geq 0} (-1)^{m-re} \binom{m}{re-1} \pmod{p}.$$

In particular if $e = p-1$, then

$$(10.10) \quad (a-1)^m p^l \beta \equiv \begin{cases} 0 \pmod{p} & (p-1 \nmid m), \\ -\frac{1}{k} \pmod{p} & (p-1 \mid m). \end{cases}$$

To prove (10.9) it is only necessary to observe that (10.8) implies

$$p^l \frac{re}{a^{re}-1} = p^l \frac{re}{(1+p^l k)^r-1} \equiv \frac{e}{k} \pmod{p}.$$

It is clear from (10.10) that the denominator of β_m may be divisible by arbitrarily high powers of p . We also remark that theorems like Theorems 3 and 4 can be framed for η_m .

When $p^e \mid a$, it is evident from (10.5) that

$$(10.11) \quad \beta_m \equiv \sum_{s=0}^m (-1)^s \binom{m}{s} (s+1) \equiv 0 \pmod{p^e} \quad (m > 1).$$

11. Congruences. The formula (7.11) together with (10.2) makes it possible to derive certain congruences satisfied by $H_m(x, q)$. We observe, to begin with, that if $q = a$ is integral $\pmod{p}$ then $u_m = [s]! a_{m,s}$ satisfies, for s fixed and $(p-1)p^{e-1} \mid w$,

$$(11.1) \quad u^m (u^w - 1)^r \equiv 0 \pmod{p^m, p^{re}},$$

where after expansion of the left member, u^n is replaced by u_n . To prove (11.1) we need only remark that

$$u^m (u^w - 1)^r = a^{-s(s-1)/2} \sum_{r=0}^s (-1)^r a^{r(r-1)/2} \begin{bmatrix} s \\ r \end{bmatrix} [s-r]^m ([s-r]^w - 1)^r.$$

If we look on x in (7.11) as an indeterminate and apply (11.1), we can assert that

$$(11.2) \quad H^m (H^w - 1)^r \equiv 0 \pmod{p^m, p^{re}}.$$

We interpret this congruence in the following manner. The left member of (11.2) is a rational function of x such that the coefficient of each term in the numerator $\equiv 0 \pmod{p^m, p^r}$. We may call (11.2) Kummer's congruence for H_m . Using (7.13) we can prove like results for $H_m(u; x)$, where u is now an integer.

In view of (1.6) the result (11.2) can be restated in terms of $A_m(x)$:

$$(11.3) \quad \sum_{s=0}^r (-1)^{r-s} \binom{r}{s} A_{m+sw}(x) \prod_{i=m+sw+1}^{m+rw} (x - a^i) \equiv 0 \pmod{p^m, p^{re}}.$$

We may state

THEOREM 5. *Let $q = a$ be integral $(\text{mod } p)$, x an indeterminate, and $r \geq 1$; then (11.3) holds.*

In the next place (11.3) implies congruences for the $A_{m,s}$ of (1.7). (For the case $q = 1$, compare [1].) Since

$$\prod_{i=m+sw+1}^{m+rw} (x - a^i) = \prod_{i=0}^{(r-s)w} (-1)^{(r-s)w-i} a^{i(i+1)/2+i(m+sw)} \begin{bmatrix} (r-s)w \\ i \end{bmatrix} x^i,$$

examination of the coefficient of x^{k-1} in (11.3) implies

$$(11.4) \quad \sum_{s=0}^r (-1)^{r-s} \binom{r}{s} \sum_i (-1)^{(r-s)w-i} A_{m+sw, k-i} a^{i(i+1)/2+i(m+sw)} \begin{bmatrix} (r-s)w \\ i \end{bmatrix} \equiv 0 \pmod{p^m, p^{re}}.$$

In order to obtain simpler results we consider some special values of the parameters. In the first place we take $r = 1$, so that (11.4) becomes

$$(11.5) \quad A_{m+w, k} - \sum_i (-1)^{w-i} A_{m, k-i} a^{i(i+1)/2+im} \begin{bmatrix} w \\ i \end{bmatrix} \equiv 0 \pmod{p^m, p^e}.$$

Now suppose first that $a \equiv 1 \pmod{p}$. It is necessary to examine

$$(11.6) \quad \begin{bmatrix} w \\ i \end{bmatrix} = \frac{(a^w - 1) \cdots (a^{w-i+1} - 1)}{(a - 1) \cdots (a^i - 1)}.$$

We assume from now on that $p > 2$. If we put $a = 1 + p^h$, $p \nmid h$, then as in the proof of Theorem 4 we find that

$$\begin{bmatrix} w \\ i \end{bmatrix} \quad \text{and} \quad \binom{w}{i}$$

are divisible by exactly the same power of p . But if $i < p^j$, it is clear from the identity

$$\binom{w}{i} = \frac{w}{i} \binom{w-1}{i-1}$$

that

$$\binom{w}{i} \equiv 0 \pmod{p^{e-j}} \quad (j \leq e).$$

Consequently if $p^{i-1} \leq k < p^j$ and $j < e$, we see that (11.5) implies

$$(11.7) \quad A_{m+w, k} \equiv A_{mk} \pmod{p^m, p^{e-j}}.$$

This proves

THEOREM 6. *Let $p \geq 3$, $q = a \equiv 1 \pmod{p}$, $p^{e-1}(p-1) \mid w$, and $p^{j-1} \leq k < p^j$, where $j < e$. Then (11.7) holds.*

When $a \not\equiv 1 \pmod{p}$ let a belong to the exponent $t \pmod{p}$. Then it is clear from (11.6) that we need only consider those factors in the right member with exponents divisible by t . Thus if i_0 is the greatest integer $\leq i/t$ we need only examine

$$\begin{bmatrix} w/t \\ i_0 \end{bmatrix}$$

with a replaced by a^t . The preceding discussion therefore applies and we obtain the following theorem which includes Theorem 6.

THEOREM 7. *Let $p \geq 3$, let $q = a$ belong to the exponent $t \pmod{p}$, $p^{e-1}(p-1) \mid w$ and $k < tp^j$, where $j < e$. Then (11.7) holds.*

The case $k = w$ is not covered by the theorem. We find for example that if $w = t = p - 1$ (so that a is a primitive root $\pmod{p}$), then

$$A_{m+p-1, k} \equiv \begin{cases} A_{m, k} & \pmod{p} & (k < p - 1), \\ A_{m, p-1} + \left(\frac{a}{p}\right) A_{m, 0} & \pmod{p} & (k = p - 1), \end{cases}$$

where (a/p) is Legendre's symbol.

Returning to (11.2) we can also consider the case in which x is put equal to an integer $\pmod{p}$, provided the resulting denominators are not divisible by p . Now the least common denominator is evidently

$$\psi_{m+rw}(x) = \prod_{s=1}^{m+rw} (x - a^s).$$

It will therefore suffice to assume that $x \not\equiv a^s \pmod{p}$ for any s . We may therefore state

THEOREM 8. *Let a and x be rational numbers that are integral $\pmod{p}$ and suppose that $x \not\equiv a^s \pmod{p}$ for any s . Let*

$$p^{e-1}(p-1) \mid w \quad \text{and} \quad r \geq 1.$$

Then

$$(11.8) \quad H^m(x)(H^m(x) - 1)^r \equiv 0 \pmod{p^m, p^{re}}.$$

In particular the theorem may be applied with slight changes to $\epsilon_m(u) = \epsilon_m(u, a)$ defined in (9.2); we have explicitly [2, (8.18)]

$$\epsilon_m(u) = \sum_{s=0}^m \frac{(-1)^s a^s}{(a+1)(a^2+1)\cdots(a^{s+1}+1)} \cdot \sum_{r=0}^s (-1)^r a^{r(r-1)/2} \begin{bmatrix} s \\ r \end{bmatrix} [u+s-r]^m,$$

which is included in (7.13). If u is an integer we have

$$\epsilon^m(u)(\epsilon^v(u) - 1)^r \equiv 0 \pmod{p^m, p^{re}}$$

provided $p \equiv 3 \pmod{4}$ and a is a quadratic residue $\pmod{p}$. For in this case -1 is a nonresidue $\pmod{p}$ and therefore $-1 \not\equiv a^s$ for any s .

12. Congruences involving η_m and β_m . Let

$$(12.1) \quad \omega_m = \omega_{m,k,r} = \frac{1}{m} \left\{ k[k]^{m-1} \eta_m \left(\frac{r}{k}, q^k \right) - \eta_m - (-1)^m \frac{k - [k]}{(q-1)^m} \right\}$$

so that by (8.5)

$$(12.2) \quad \omega_m = \frac{1}{q} \sum_{\zeta \neq 1} \frac{\zeta^{r+1}}{1-\zeta} H_{m-1}(\zeta q^{-1}),$$

where ζ runs through the k th roots of unity distinct from 1. As for the denominators in the right member of (12.2), note that

$$\prod_{\zeta \neq 1} (a^s - \zeta) = \frac{a^{ks} - 1}{a^s - 1} = a^{s(k-1)} + \cdots + a^s + 1,$$

which is prime to p for all s provided $p \nmid k$. We may therefore state

THEOREM 9. *If a is integral $\pmod{p}$ and $p \nmid k$, then*

$$(12.3) \quad \omega^m(\omega^v - 1)^r \equiv 0 \pmod{p^{m-1}, p^{re}},$$

where ω_m is defined by (12.1) and $p^{e-1}(p-1) \mid v$.

As for β_m we have

$$(12.4) \quad \begin{aligned} & k[k]^{m-1} q^r \beta_m \left(\frac{r}{k}, q^k \right) - \beta_m \\ &= \frac{(m+1)(q-1)}{q} \sum_{\zeta \neq 1} \frac{\zeta^{r+1}}{1-\zeta} H_m(\zeta q^{-1}) + \frac{m}{q} \sum_{\zeta \neq 1} \frac{\zeta^{r+1}}{1-\zeta} H_{m-1}(\zeta q^{-1}) \end{aligned}$$

analogous to (8.5). In much the same way as above (12.4) implies

THEOREM 10. *If a is integral $\pmod{p}$ and $p \nmid k$ then*

$$(12.5) \quad \Omega^m(\Omega^v - 1)^r \equiv 0 \pmod{p^{m-1}, p^{(r-1)e}},$$

where Ω_m stands for the left member of (12.4) and $p^{s-1}(p-1)|w$.

Unfortunately we seem unable to obtain simpler congruences for β_m and η_m .

13. Combinatorial interpretation of a_{msr} . Put

$$A_{ms}^* = \sum_{r=0}^{(s-1)(m-s)} a_{msr_0} q^r$$

$$(r_0 = s(s-1)/2 + r).$$

The following combinatorial interpretation of the coefficients a_{msr} was kindly suggested by J. Riordan. The number a_{msr} is the number of permutations of m things requiring s readings and such that $r=r_2+2r_3+\cdots+(s-1)r_s$, where r_k is the number of elements read on the k th reading. The following numerical illustration for $m=4$ was also supplied by Riordan.

Permutation	Reading	s	r
1234	1234	1	0
1243 1423 4123	123 4	2	1
1324 1342 3124 3142 3412	12 34	2	2
2134 2314 2341	1 234	2	3
1432 4132 4312	12 3 4	3	3
2134 2413 2431 4213 4231	1 23 4	3	4
3214 3241 3421	1 2 34	3	5
4321	1 2 3 4	4	6
